NONCOMMUTATIVE VERSIONS OF SOME CLASSICAL
BIRATIONAL TRANSFORMATIONS.

DENNIS PRESOTTO AND MICHEL VAN DEN BERGH

Abstract. In this paper we generalize some classical birational transfor-
mations to the non-commutative case. In particular we show that 3-di-
dimensional quadratic Sklyanin algebras (non-commutative projective planes) and 3-di-
dimensional cubic Sklyanin algebras (non-commutative quadrics) have the same function
field. In the same vein we construct an analogue of the Cremona transform
for non-commutative projective planes.

1. Introduction

Below $k$ is an algebraically closed field. Artin-Schelter regular algebras were in-
troduced in [1] and subsequently classified in dimension three [1, 3, 8]. Throughout
we will only consider three-dimensional AS-regular algebras generated in degree
one. For such algebras $A$ there are two possibilities:

(1) $A$ is generated by three elements satisfying three quadratic relations (the
“quadratic case”). In this case $A$ has Hilbert series $1/(1 - t)^3$, i.e. the same
Hilbert series as a polynomial ring in three variables.

(2) $A$ is generated by two elements satisfying two cubic relations (the “cubic
case”). In this case $A$ has Hilbert series $1/(1 - t)^2(1 - t^2)$.

For use below we define $(r, s)$ to be respectively the number of generators of $A$ and
the degrees of the relations. Thus $(r, s) = (3, 2)$ or $(2, 3)$ depending on whether $A$
is quadratic or cubic.

The first author was supported by a Ph.D. fellowship of the Research Foundation Flanders
(FWO), the second author is a senior researcher of the FWO.
If $B = k + B_1 + B_2 + \ldots$ is an $\mathbb{N}$-graded ring satisfying suitable conditions then we can associate a non-commutative scheme $\text{Proj } B$ to it whose category of quasi-coherent sheaves is defined to be $QGr(B) \overset{\text{def}}{=} \text{Gr}(B)/\text{Tors}(B)$ where $\text{Gr}(B)$ is the category of graded right $B$-modules and $\text{Tors}(B)$ is the category of graded right $B$-modules that have locally right bounded grading [5]. When $A$ is a quadratic three-dimensional AS-regular algebra then $\text{Proj } A$ may be thought off as a non-commutative quadric. The rationale for this is explained in [23].

The classification of three-dimensional AS-regular algebras $A$ is in terms of suitable geometric data $(Y, \sigma, \mathcal{L})$ where $Y$ is a $k$-scheme, $\sigma$ is an automorphism of $Y$ and $\mathcal{L}$ is a line bundle on $Y$.

More precisely: in the quadratic case $Y$ is either $\mathbb{P}^2$ (the “linear case”) or $Y$ is embedded as a divisor of degree 3 in $\mathbb{P}^2$ (the “elliptic case”) and $\mathcal{L}$ is the restriction of $\mathcal{O}_{\mathbb{P}^2}(1)$. In the cubic case $Y$ is either $\mathbb{P}^1 \times \mathbb{P}^1$ (the “linear case”) or $Y$ is embedded as a divisor of bidegree $(2,2)$ in $\mathbb{P}^1 \times \mathbb{P}^1$ (the “elliptic case”) and $\mathcal{L}$ is the restriction of $\mathcal{O}_{\mathbb{P}^1 \times \mathbb{P}^1}(1,0)$. The geometric data must also satisfy an additional numerical condition which we will not discuss here.

Starting from the geometric data $(Y, \sigma, \mathcal{L})$ we construct a so-called “twisted homogeneous coordinate ring” $B = B(Y, \sigma, \mathcal{L})$. It is an $\mathbb{N}$-graded ring such that

$$B_n = \Gamma(Y, \mathcal{L} \otimes \mathcal{L}^\sigma \otimes \ldots \otimes \mathcal{L}^{\sigma^{n-1}})$$

with product $a \cdot b = a \otimes b^{\sigma^n}$ for $|a| = n$. The corresponding AS-regular algebra $A = A(Y, \sigma, \mathcal{L})$ is obtained from $B$ by dropping all relations in degree $> s$. By virtue of the construction there is a graded surjective $k$-algebra homomorphism $A \to B$ and this is an isomorphism in the linear case and it has a kernel generated by a normal element $g$ in degree $s + 1$ in the elliptic case.

According to [4] there is an equivalence of categories $QGr(B) \cong \text{Qch}(Y)$. In our current language this can be written as

$$\text{Proj } B \cong Y$$

So the non-commutative scheme $X = \text{Proj } A$ contains the commutative scheme $Y$ (via the surjection $A \to B$). In the linear case $X = Y$, and in the quadratic case $Y$ is a so-called “divisor” in $X$ [22, Section 3.6].

If $Y$ is a smooth elliptic curve, $\sigma$ is a translation such that $\sigma^{s+1} \neq \text{id}$ and $\mathcal{L}$ is a line bundle of degree $r$ then we call the corresponding AS-regular algebra a Sklyanin algebra. In that case the normal element $g$ is actually central. Since any two line bundles of the same degree on a smooth elliptic curve are related by a translation, which necessarily commutes with $\sigma$, it is easy to see that the resulting Sklyanin algebra depends up to isomorphism only on $(E, \sigma)$. So we sometimes drop $\mathcal{L}$ from the notation. Furthermore $\text{Proj } A$ does not change if we compose $\sigma$ with a translation by a point of order $s + 1$ (See for example [2, §8]). In other words $\text{Proj } A$ depends only on $\sigma^{s+1}$.

A three-dimensional AS-regular algebra $A$ is a noetherian domain and in particular it has a graded field of fractions $\text{Frac}(A)$ in which we invert all non-zero homogeneous elements of $A$. The part of degree zero $\text{Frac}_0(A)$ of $\text{Frac}(A)$ will be called the function field of $\text{Proj } A$.

In this note we prove the following result announced in [20]. A similar result by Rogalski-Sierra-Stafford was announced in [18].
Theorem 1.1. If $A$, $A'$ are a cubic and a quadratic Sklyanin algebra respectively with geometric data $(Y, \sigma)$ and $(Y, \psi)$ such that $\sigma^3 = \psi^4$. Then $\text{Proj} A$ and $\text{Proj} A'$ have the same function field.

The proof of this result is geometric. In the commutative case the passage from $\mathbb{P}^1 \times \mathbb{P}^1$ to $\mathbb{P}^2$ goes by blowing up a point $p$ and then contracting the strict transforms of the two rulings through this point. One may short circuit this construction by considering a suitable linear system on $\mathbb{P}^1 \times \mathbb{P}^1$ with base point in $p$. It is this construction that we generalize first. To do this we have to step outside the category of graded algebras and work in the slightly larger category of $\mathbb{Z}$-algebras (additive categories whose objects are indexed by $\mathbb{Z}$, see §2 below).

So what we will actually do is the following: let $A$ be a cubic Sklyanin algebra and let $A^{(2)}$ be its 2-Veronese with the corresponding $\mathbb{Z}$-algebra being denoted by $\hat{A}^{(2)}$. Associated to a point $p \in Y$ we will construct a sub-$\mathbb{Z}$-algebra $D$ of $\hat{A}^{(2)}$ which is 3-dimensional quadratic Artin-Schelter $\mathbb{Z}$-algebra in the sense of [23]. Again invoking [23] this $\mathbb{Z}$-algebra must correspond to a 3-dimensional quadratic Artin-Schelter graded algebra $A'$. It will turn out that the geometric data of $A$ and $A'$ are related as in Theorem 1.1. Note that the use of $\mathbb{Z}$-algebras is essential here as there is no direct embedding $A' \hookrightarrow A^{(2)}$ of graded rings.

Another classical birational transformation is the so-called “Cremona transform”. It is obtained by blowing up the tree vertices of a triangle and then contracting the sides. In this note we will also show that the Cremona transform has a non-commutative version and that it yields an automorphism of the function field of a three-dimensional quadratic Sklyanin algebra. The properties of this automorphism will be discussed elsewhere.

In §8 we explain how in the non-commutative case the approach via linear systems is related to the blowup construction introduced in [22].

Remark 1.2. A more ring-theoretic approach to blowups of noncommutative surfaces was taken by Rogalski-Sierra-Stafford in [15]. They also used this technique in their companion paper [14] to classify certain orders in a generic 3-dimensional Sklyanin algebra.

Remark 1.3. Cubic 3-dimensional Artin-Schelter regular algebras are a special case of the non-commutative quadrics introduced in [23]. Theorem 1.1 generalizes to such quadrics but the proof becomes slightly more technical. For this reason we have chosen to write down the proof of Theorem 1.1 separately.

2. Reminder on AS-regular $\mathbb{Z}$-algebras

For background material on $\mathbb{Z}$-algebras see [17] and also sections 3 and 4 of [23]. Recall that a $(k)$-$\mathbb{Z}$-algebra is defined as a $k$-algebra $A$ (without unit) with a decomposition $A = \bigoplus_{(m,n) \in \mathbb{Z}^2} A_{m,n}$ such that the multiplication satisfies $A_{m,n}A_{m,j} \subset A_{m,j}$ and $A_{m,n}A_{i,j} = 0$ if $n \neq i$. Moreover we require the existence of local units $e_n \in A_{n,n}$ satisfying $e_mx = x = xe_n$ whenever $x \in A_{m,n}$. The category of $\mathbb{Z}$-algebras is denoted by $\text{Alg}(\mathbb{Z})$. Every graded $k$-algebra $A$ gives rise to a $\mathbb{Z}$-algebra $\hat{A}$ via $\hat{A}_{m,n} = A_{m-n}$. Most graded notions have a natural $\mathbb{Z}$-algebra counterpart. For example we say that $A \in \text{Alg}(\mathbb{Z})$ is positively graded if $A_{m,n} = 0$ whenever $m > n$. 
A \mathbb{Z}\text{-algebra} over \( k \) is said to be connected, if it is positively graded, each \( A_{m,n} \) is finite dimensional over \( k \) and \( A_{m,m} \cong k \) for all \( m \).

If \( A \in \text{Alg}(\mathbb{Z}) \) then we say \( M \) is a graded right-\( A \)-module if it is a module in the usual sense together with a decomposition \( M = \bigoplus_{n} M_{n} \) satisfying \( M_{m} A_{m,n} \subset M_{n} \) and \( M_{m} A_{i,n} = 0 \) if \( i \neq m \). We denote the category of graded \( A \)-modules by \( \text{Gr}(A) \).

(Obviously \( \text{Gr}(A) = \text{Gr}(\hat{A}) \) if \( A \) is a graded ring.) If \( A \) is a connected \( \mathbb{Z} \)-algebra over \( k \) we denote the graded \( A \)-modules \( P_{n,A} = e_{n} A \) and \( S_{n,A} \cong k \) is the unique simple quotient of \( P_{n,A} \).

**Definition 2.1.** A \( \mathbb{Z} \)-algebra \( A \) over \( k \) is said to be AS-regular if the following conditions are satified:

1. \( A \) is connected
2. \( \dim_{k}(A_{m,n}) \) is bounded by a polynomial in \( n - m \)
3. The projective dimension of \( S_{n,A} \) is finite and bounded by a number independent of \( n \)
4. \( \forall n \in \mathbb{N} : \sum_{i,j} \dim_{k} \left( \text{Ext}^{i}_{\text{Gr}(A)}(S_{j,A}, P_{n,A}) \right) = 1 \)

It is immediate that if a graded algebra \( A \) is AS-regular in the sense of \( [3] \), then \( \hat{A} \) is AS-regular in the above sense.

\( \mathbb{Z} \)-algebra analogues of three dimensional quadratic and cubic Artin-Schelter regular algebras were classified in \([23]\) (following \([6]\) in the quadratic case). We will describe the quadratic case as this is the only case we will need. In this case the classification is in terms of triples \( (Y, \mathcal{L}_{0}, \mathcal{L}_{1}) \) where \( Y \) is either a (possibly singular, non-reduced) curve of arithmetic genus 1 (the “elliptic case”) or \( Y = \mathbb{P}^{2} \) (the “linear case”) and \( \mathcal{L}_{0}, \mathcal{L}_{1} \) are line bundles of degree 3 on \( Y \) such that \( \mathcal{L}_{0} \neq \mathcal{L}_{1} \) in the elliptic case and \( \mathcal{L}_{0} = \mathcal{L}_{1} = \mathcal{O}_{Y^{2}}(1) \) in the linear case. The triple must satisfy some other technical conditions which are however vacuous in the case that \( Y \) is a smooth elliptic curve.

To construct a \( \mathbb{Z} \)-algebra from this data we first introduce the “elliptic helix” \( (\mathcal{L}_{i})_{i \in \mathbb{Z}} \) associated to \( (\mathcal{L}_{0}, \mathcal{L}_{1}) \). This is a collection of line bundles satisfying

\[ \mathcal{L}_{i} \otimes_{\mathcal{O}_{Y}} \mathcal{L}_{i+1}^{-2} \otimes_{\mathcal{O}_{Y}} \mathcal{L}_{i+2} = \mathcal{O}_{Y} \]

We put \( V_{i} = H^{0}(Y, \mathcal{L}_{i}) \) and

\[ R_{i} = \ker \left( H^{0}(Y, \mathcal{L}_{i}) \otimes H^{0}(Y, \mathcal{L}_{i+1}) \to H^{0}(Y, \mathcal{L}_{i} \otimes_{\mathcal{O}_{Y}} \mathcal{L}_{i+1}) \right) \]

By definition the quadratic AS-regular \( \mathbb{Z} \)-algebra \( A = (Y, \mathcal{L}_{0}, \mathcal{L}_{1}) \) associated to \( (Y, \mathcal{L}_{0}, \mathcal{L}_{1}) \) is generated by \( V_{i}(= A_{i,i+1}) \) subject to the relations \( R_{i} \subset V_{i} \otimes V_{i+1} \).

The “Hilbert function” of \( A \) is

\[ \dim A_{m,m+a} = \begin{cases} \frac{(a+1)(a+2)}{2} & \text{if } a \geq 0 \\ 0 & \text{if } a < 0 \end{cases} \]

Using the line bundles \( (\mathcal{L}_{i})_{i} \) be may define a \( \mathbb{Z} \)-algebra analogue \( B = B(Y, (\mathcal{L}_{i})_{i}) \) of a twisted homogeneous coordinate ring (see the introduction) where

\[ B_{m,n} = \Gamma(Y, \mathcal{L}_{m} \otimes \ldots \otimes \mathcal{L}_{n-1}) \]

If \( A \) is the 3-dimensional AS-regular \( \mathbb{Z} \)-algebra constructed above then there is a surjective map

\[ \phi : A \to B \]
where $A$ is obtained from $B$ by dropping all relations in degree $(m, n)$ for $n \geq m + s + 1$.

If $A$ is 3-dimensional quadratic AS-regular algebra with geometric data $(Y, \sigma, \mathcal{L})$ then the elliptic helix corresponding to $A$ is $(\mathcal{L}^\sigma)_i$. This follows immediately from the construction of $A$ from $(Y, \sigma, \mathcal{L})$ as given in [3] (see the introduction for an outline).

3. Non-commutative geometry

It will be convenient to use the formalism of non-commutative geometry used in [22] which we summarize here. For more details we refer to loc. cit.. See also [19]. We will change the terminology and notations slightly to be more compatible with current conventions.

For us a non-commutative scheme will be a Grothendieck category (i.e. an abelian category with a generator and exact filtered colimits). To emphasize that we think of non-commutative schemes as geometric objects, we denote them by roman capitals $X, Y, \ldots$. When we refer to the category represented by a non-commutative scheme $X$ then we write $\mathcal{Q}ch_p X$. A morphism $\alpha: X \to Y$ between non-commutative schemes will be a right exact functor $\alpha: \mathcal{Q}ch_p Y \to \mathcal{Q}ch_p X$ possessing a right adjoint (denoted by $\alpha^*$). In this way the non-commutative schemes form a category (more accurately: a two-category).

In this paper we often view commutative schemes as non-commutative schemes. More precisely if $X$ is a commutative scheme, then $\mathcal{Q}ch_p X$ will be the category of quasi-coherent sheaves on $X$. It is proved in [9] that this is a Grothendieck category. Furthermore $X$ can be recovered from $\mathcal{Q}ch_p X$ [7, 10, 16].

If $X$ is a non-commutative scheme then we think of objects in $\mathcal{Q}ch_p X$ as sheaves of right modules on $X$. To define the analogue of a sheaf of algebras on $X$ however we need a category of bimodules on $X$ (see [21] for the case where $X$ is commutative). The most obvious way to proceed is to define the category $\text{Bimod}(X - Y)$ of $X - Y$-bimodules as the right exact functors $\mathcal{Q}ch_p X \to \mathcal{Q}ch_p Y$ commuting with direct limits. The action of a bimodule $N$ on an object $M \in \mathcal{Q}ch_p X$ is written as $M \otimes_X N$.

If we define the “tensor product” of bimodules as composition then we can define algebra objects on $X$ as algebra objects in the category of $X - X$-bimodules and in this we may extend much of the ordinary commutative formalism. For example the identity functor $\mathcal{Q}ch(X) \to \mathcal{Q}ch(X)$ is a natural analogue of the structure sheaf, and as such it will be denoted by $\mathcal{O}_X$. If $A$ is an algebra object on $X$ then it is routine to define an abelian category $\text{Mod}(A)$ of right-$A$-modules. We have $\text{Mod}(\mathcal{O}_X) = \mathcal{Q}ch(X)$. Unraveling all the definitions it turns out that $- \otimes_X -$ (the “tensor product” (composition) in the monoidal category $\text{Bimod}(X - X)$) and $- \otimes_{\mathcal{O}_X} -$ (the tensor product over the algebra $\mathcal{O}_X$) have the same meaning. We will use both notations, depending on the context.

Unfortunately $\text{Bimod}(X - Y)$ appears not to be an abelian category and this represents a technical inconvenience which is solved in [22] by embedding $\text{Bimod}(X - Y)$ into a larger category $\text{BIMOD}(X - Y)$ consisting of “weak bimodules”. The category $\text{BIMOD}(X - Y)$ is opposite to the category of left exact functors $\mathcal{Q}ch_p Y \to \mathcal{Q}ch_p X$. Since left exact functors are determined by their values on injectives, they trivially form an abelian category. The category $\text{Bimod}(X - Y)$ is the full category of
BIMOD(\(X - Y\)) consisting of functors having a left adjoint. Or equivalently: functors commuting with direct products.

This being said, these technical complication will be invisible in this paper as all bimodules we encounter will be in Bimod(\(X - Y\)).

If \(A\) be a graded algebra then the associated non-commutative scheme \(X = \text{Proj } A\) is defined by \(\text{Qch}(X) = \text{QGr}(A) = \text{Gr}(A)/\text{Tors}(A)\), as discussed above. Note that \(\text{Proj } A\) is only reasonably behaved when \(A\) satisfies suitable homological conditions. See [5, 13]. We denote the quotient functor \(\text{Gr}(A) \rightarrow \text{QGr}(A)\) by \(\pi\). The object \(\pi A\) is denoted by \(\mathcal{O}_X\). The “shift by \(n\)” functor \(\text{Qch}(X)\) is written as \(\mathcal{M} \mapsto \mathcal{M}(n)\) and the corresponding bimodule is written as \(\mathcal{O}_X(n)\). In particular \(\mathcal{O}_X = \mathcal{O}_X(0)\) and \(\mathcal{O}_X(n) = \mathcal{O} \otimes_{\mathcal{O}_X} \mathcal{O}_X(n) = \pi(A(n))\).

4. Construction of the subalgebra \(D\) of \(\bar{A}^{(2)}\)

We devote the rest of the paper to the proof of Theorem 1.1 as well as the construction of the non-commutative Cremona transform. The treatment of both constructions will be almost entirely parallel. So let \(A\) be a 3-dimensional Sklyanin algebra, which may be either quadratic or cubic, and put \(X = \text{Proj } A\).

As explained in the introduction (see also [3]) \(A\) corresponds to a triple \((Y, \sigma, \mathcal{L})\), where \(Y\) is smooth elliptic curve, \(\sigma\) is a translation and \(\mathcal{L}\) is a line bundle of degree \(r\) on \(Y\). The relation is given by the fact there is a regular central element \(g \in A_{s+1}\) such that \(A/(g) = B(Y, \sigma, \mathcal{L})\) where \(B = B(Y, \sigma, \mathcal{L})\) is a so-called “twisted homogeneous coordinate ring” (see (1.1)).

Using the resulting equivalence of categories (see the introduction and [4])

\[
\text{Proj } B \cong Y
\]

we will write \(\mathcal{O}_Y(n) \in \text{Bimod}(Y - Y)\) for the shift by \(n\)-functor on \(\text{Proj } B\). Then we have

\[
\mathcal{O}_Y(1) = \sigma_\mathcal{L}( - \otimes_{\mathcal{O}_Y} \mathcal{L})
\]

(the tensor product takes place in the category of sheaves of \(Y\)-modules).

The inclusion functor \(\text{Qch}(Y) \subset \text{Qch}(X)\) (i.e. the functor dual to the graded algebra morphism \(A \rightarrow B\)) has a left adjoint which we denote by \(- \otimes_{\mathcal{O}_X} \mathcal{O}_Y\) (on the level of graded modules it corresponds to tensoring by \(A/gA\)). Note that in this way \(\mathcal{O}_Y\) is viewed as a \(X - Y\)-bimodule.

Below we will routinely regard a sheaf of \(\mathcal{O}_Y\)-modules \(\mathcal{N}\) as an object in \(\text{Bimod}(Y - Y)\) by identifying it with the functor \(- \otimes_{\mathcal{O}_Y} \mathcal{N}\). It is easy to see that the resulting functor

\[
\text{Qch}(Y) \rightarrow \text{Bimod}(Y - Y) \subset \text{BIMOD}(Y - Y)
\]

is fully faithful and exact.

Similarly we regard an \(Y - Y\)-bimodule \(\mathcal{M}\) as an \(X - X\)-bimodule by defining the corresponding functor to be

\[
\text{Qch}(X) \xrightarrow{- \otimes_{\mathcal{O}_X} \mathcal{O}_Y} \text{Qch}(Y) \xrightarrow{- \otimes_{\mathcal{O}_Y} \mathcal{M}} \text{Qch}(Y) \hookrightarrow \text{Qch}(X)
\]

In this way \(\mathcal{O}_Y\) becomes an \(X - X\)-bimodule and one checks that it is in fact an algebra quotient of \(\mathcal{O}_X\). Note that \(\mathcal{O}_Y\) now denotes both an algebra on \(X\) and an algebra on \(Y\) (the identity functor) but for both interpretations we have \(\text{Mod}(\mathcal{O}_Y) \cong \text{Qch}(Y)\).
For use in the sequel we write
\[ o_X(-Y) = \ker (o_X \to o_Y) \]
o_X(-Y) is the ideal in o_X corresponding to the graded ideal gA \subset A. Note that since g is central we have in fact o_X(-Y) = o_X(-3).

If \( M \in \text{Qch}(X) \) then we define the “global sections” of \( M \) as
\[ \Gamma(X, M) = \text{Hom}_X(O_X, M) \]
Similarly we define the global sections of an \( X - X \)-bimodule \( N \) as in [22, Section 3.5]:
\[ \Gamma(X, N) := \text{Hom}(O_X, O_X \otimes_{o_X} N) \]
Use of the functor \( \Gamma(X, -) \) on bimodules requires some care since it is apriori not left exact. However in our applications it will be.

Note that \( N \) is an algebra object in the category of bimodules then \( \Gamma(X, N) \) is in fact an algebra for purely formal reasons. The same holds true for graded algebras and \( \mathbb{Z} \)-algebras.

It is easy to see that \( A_n \) is equal to the global sections of \( o_X(n) \):
\[
\Gamma(X, o_X(n)) := \text{Hom}_X(O_X, O_X(n)) \\
= \text{Hom}_{\text{QGr}(A)}(\pi(A), \pi(A(n))) \\
= \text{Hom}_{\text{QGr}(A)}(A, A(n)) \quad [5, \text{Theorem 8.1(5)}] \\
= A_n
\]
where the third equality follows from the AS-regularity of \( A \). Thus for the \( \mathbb{Z} \)-algebra associated to the two-Veronese of \( A \) we have:
\[ A^{[2]}_{m,n} = \Gamma(X, o_X(2(n - m))) = \Gamma(X, o_X(-2m) \otimes_{o_X} o_X(2n)) \]

Below \( (p_i)_i \) is a collection of points on \( Y \): three distinct points in case \( (r, s) = (3,2) \) and one point in case \( (r, s) = (2,3) \). Let \( d = \sum_i p_i \) be the corresponding divisor on \( Y \). As above we consider \( O_d \) as a \( Y - Y \)-bimodule but to avoid confusion we write it as \( o_d \). Following our convention above we also consider \( o_d \) as an \( X \)-bimodule. Put
\[
m_{d,Y} = \ker (o_Y \to o_d) \\
m_d = \ker (o_X \to o_d)
\]
Clearly \( m_{d,Y} \in \text{Bimod}(Y - Y) \) as \( m_{d,Y} \) corresponds to an ordinary ideal sheaf in \( O_Y \) (see (4.1) above). The fact that \( m_d \in \text{Bimod}(X - X) \) follows by applying [22, Corollary 5.5.6] repeatedly for the different \( p_i \).

Finally consider the following bimodules over \( X \), respectively \( Y \):
\[
(D_Y)_{m,n} = \begin{cases} 
    o_Y(-2m) \otimes_{o_Y} m_{r-m,d,Y} \cdots m_{r-n+1,d,Y} \otimes_{o_Y} o_Y(2n) & \text{if } n \geq m \\
    0 & \text{if } n < m
\end{cases}
\]
\[
(D)_{m,n} = \begin{cases} 
    o_X(-2m) \otimes_{o_X} m_{r-m,d} \cdots m_{r-n+1,d} \otimes_{o_X} o_X(2n) & \text{if } n \geq m \\
    0 & \text{if } n < m
\end{cases}
\]
where \( \tau = \sigma^{s+1} \). Here \( m_{r-i,d} \) is the image of
\[
m_{r-i,d} \otimes_X \cdots \otimes_X m_{r-i,d} \to o_X \otimes_X \cdots \otimes_X o_X = o_X
\]
A priori this image lies only in \( \text{BIMOD}(X - X) \) but with the same method as the proof of [22, Proposition 6.1.1] one verifies that it lies in fact in \( \text{Bimod}(X - X) \).
The collections of bimodules \( D \equiv \bigoplus_{m,n} \mathcal{D}_{m,n}, \mathcal{D}_Y \equiv \bigoplus_{m,n} (\mathcal{D}_Y)_{m,n} \) represent \( \mathbb{Z} \)-algebra objects respectively in \( \text{Bimod}(X - X) \) and \( \text{Bimod}(Y - Y) \). For example the product

\[
\mathcal{D}_{m,n} \otimes_{\mathcal{O}_X} \mathcal{D}_{n,p}
\]

is given by

\[
\text{Hom}(\mathcal{O}_Y, \mathcal{O}_Y(-2m) \otimes \mathcal{M}_{m,n}) = \text{Hom}(\mathcal{O}_Y, \mathcal{O}_Y(-2m) \otimes \mathcal{M}_{m,n})
\]

Denote the global sections of \( \mathcal{D}_Y \) by \( D \), \( D_Y \) respectively. Thus \( D \) and \( D_Y \) are both \( \mathbb{Z} \)-algebras.

We now have to check that the \( \mathcal{D}_{m,n} \otimes \mathcal{O}_X \mathcal{D}_{n,p} \) for \( m,n \geq 1 \) is an autoequivalence compute for \( n \geq m \)

\[
(\mathcal{D}_Y)_{m,n} = B(Y, \{\mathcal{L}_i\})_{m,n} := \Gamma(Y, \mathcal{L}_m \otimes \ldots \otimes \mathcal{L}_{n-1})
\]

The functor \(-\otimes_{\mathcal{O}_Y} m_{d,Y}\) is given by \(-\otimes_{\mathcal{O}_Y} \mathcal{M}_{d,Y}\) where \( \mathcal{M}_{d,Y} \) is the ideal sheaf of \( d \) on \( Y \) (see (4.1) above). Moreover as we have already mentioned \( \sigma_1(1) = \sigma_a(-\otimes_{\mathcal{O}_Y} \mathcal{L}) \)

\[
\mathcal{L}_i = \mathcal{M}_{1-d,Y} \otimes \mathcal{L}_{\sigma^{2i}} \otimes \mathcal{L}_{\sigma^{2i+1}}
\]

A routine but somewhat tedious verification shows that the isomorphism constructed in (5.1) sends the product on the left to the obvious product on the right corresponding to the tensor product.

We now have to check that the \( \{\mathcal{L}_i\} \) constitute an elliptic helix as introduced in §2. Using our standing hypothesis that \( Y \) is smooth (since \( A \) was assumed to be a Sklyanin algebra) we must verify the following facts.
Proof. We compute in the quadratic case where Lemma 5.1.

If \( \psi \) is an arbitrary translation satisfying \( \psi^3 = \sigma^4 \).

Thus taking into account that in the quadratic case

\[
\sigma^*(\mathcal{L}_i) = \mathcal{L}_{i+1}
\]

and if \( A \) is cubic

\[
\psi^*(\mathcal{L}_i) = \mathcal{L}_{i+1}
\]

where \( \psi \) is an arbitrary translation satisfying \( \psi^3 = \sigma^4 \).

Let \( N \) be a line bundle of degree zero such that for any line bundle \( M \) on \( Y \) we have the following identities in Pic(\( Y \)):

\[
[\sigma^* M] = [M] \cdot [N]
\]

This statement is true in even higher generality, see [23, Theorem 4.2.3] Thus

\[
[\sigma^*(\mathcal{L}_i) \otimes \mathcal{L}_{i+1}^{-1}] = (\deg(\mathcal{M}_{s, d, Y}) + \deg(\mathcal{L}^{\sigma^3}) - 3 \deg(\mathcal{M}_{s, d, Y}) - 3 \deg(\mathcal{L}^{\sigma^3})) [N] = 0
\]

taking into account that in the quadratic case

\[
\deg(\mathcal{M}_{s, d, Y}) = - \deg d = -3
\]
\[
\deg(\sigma^{21} \mathcal{L}) = 3
\]

Now we consider the cubic case. It will be convenient to introduce a translation \( \sigma_3 \) which is a cube root of \( \sigma \)

\[
\sigma^3 (\mathcal{L}_i) \otimes \mathcal{L}_{i+1}^{-1} = \mathcal{M}_{s, d, Y}^{\sigma_3} \otimes \mathcal{L}^{\sigma_3^{6+i}} \otimes \mathcal{L}^{\sigma_3^{6+i}} \otimes (\mathcal{M}_{s, d, Y}^{\sigma_3^{12}})^{-1} \otimes (\mathcal{L}^{\sigma_3^{6+i}})^{-1} \otimes \mathcal{L}^{\sigma_3^{6+i}}
\]

Let \( \mathcal{N}_3 \) be a line bundle of degree zero such that for any line bundle \( \mathcal{M} \)

\[
[\sigma^3 \mathcal{M}] = [\mathcal{M}] \cdot [\mathcal{N}_3]
\]

We obtain

\[
[\sigma^3 (\mathcal{L}_i) \otimes \mathcal{L}_{i+1}^{-1}] = (4 \deg(\mathcal{M}_{s, d, Y}) + 4 \deg(\mathcal{L}^{\sigma^3}) + 7 \deg(\mathcal{L}^{\sigma^3}) - 12 \deg(\mathcal{M}_{s, d, Y}) - 6 \deg(\mathcal{L}^{\sigma^3}) - 9 \deg(\mathcal{L}^{\sigma^3})) [\mathcal{N}_3] = 0
\]

taking into account that this time

\[
\deg(\mathcal{M}_{s, d, Y}) = - \deg d = -1
\]
\[
\deg(\mathcal{L}^{\sigma^3}) = 2
\]
\[
\square
\]

We now verify that \((\mathcal{L}_i)_{1}\) is an elliptic helix. Condition (1) is immediate and condition (3) follows from Lemma 5.1. Assume that (2) is false in the quadratic case. Then \( \sigma^*(\mathcal{L}_0) = \mathcal{L}_0 \). In other words \( \sigma \) is translation by a point of order three. But this contradicts our assumption that \( A \) is a Sklyanin algebra. Now assume that (2) is false in the cubic case. The \( \psi \) is a translation by a point of order three and
from the definition of $\psi$ it follows that $\sigma$ is translation by a point of order four, again contradicting the fact that $A$ is Sklyanin algebra.

6. Showing that $D$ is AS-regular

For use below recall some some commutation formulas. First note that since $o_Y(1) = \sigma_a(\mathcal{O} \otimes \mathcal{L})$ we have

$$o_d \otimes o_Y o_Y(1) = o_Y(1) \otimes o_Y o_d$$

(we may see this by applying both sides to an object in $\text{Qch}(Y)$). Using the definitions of $m_d$, $m_d,Y$ (see (4.2), (4.3)) we deduce from this

$$m_d,Y \otimes o_Y o_Y(1) = o_Y(1) \otimes o_Y m_{d,Y}$$

$$m_d \otimes o_X o_X(1) = o_X(1) \otimes o_X m_{d}$$

Similar formulas also hold for longer products of $m$’s such as for example appear in the definition of $(D_{\gamma})_{m,n}$ and $D_{m,n}$.

If $M$ is a bimodule then we will write $O_X(a) \otimes o_X M$. Thus the “right structure” of $M$ is $(O)M$. For the sequel we need a resolution of $(a)D_{m,m+1}$. In the quadratic case we use the following lemma.

Lemma 6.1. Let $A$ be a quadratic AS-regular algebra of dimension 3. Let $q_1, q_2, q_3$ be distinct non-collinear points in $Y$ and let $Q_1, Q_2, Q_3$ be the corresponding point modules. Pick an $m$ in $(Q_1 \oplus Q_2 \oplus Q_3)_0$ whose three components are non-zero and let $M = mA$. Then the minimal resolution of $M$ has the following form

$$0 \to A(-3)^{\oplus 2} \to A(-2)^{\oplus 3} \to A \to M \to 0$$

Proof. Let $g$ be the normalizing element of degree three in $A$ and let $B = A/gA$. By using the explicit category equivalence $\text{Qch}(B) \cong Q\text{Gr}(Y)$ one easily proves that the map $B_{\geq 1} \to M_{\geq 1}$ is surjective. Whence the corresponding map $u : A_{\geq 1} \to M_{\geq 1}$ is also surjective.

Look at the exact sequence

$$0 \to \ker u \to A_{\geq 1} \to M_{\geq 1} \to 0$$

Tensoring this exact sequence with $k$ yields an exact sequence

$$\text{Tor}^A_1(M_{\geq 1}, k) \to \ker u \otimes_A k \to A_{\geq 1} \otimes_A k \to M_{\geq 1} \otimes k \to 0$$

Now both $A_{\geq 1}$ and $M_{\geq 1}$ are generated in degree one and furthermore $\text{dim} A_1 = \text{dim} M_1$. Hence it follows that $\tilde{u}$ is an isomorphism. Therefore $\ker u \otimes_A k$ is a quotient of $\text{Tor}^A_1(M_{\geq 1}, k)$. From the fact that $M_{\geq 1}$ is a sum of shifted point modules we compute that $\text{Tor}^A_1(M_{\geq 1}, k) = k(-2)^3$. Thus $\ker u$ is a quotient of $A(-2)^3$. Now using the fact that $M$ has no torsion and hence has projective dimension two we may now complete the full resolution of $M$ using a Hilbert series argument. □

Note that

$$D_{m,m+1} = o_X(-2m) \otimes o_X m_{\sigma - \sigma d} \otimes o_X o_X(2(m + 1))$$

and thus

$$O_X(a) \otimes o_X D_{m,m+1} = (O_X \otimes o_X m_{\sigma - \sigma - \sigma d})(a + 2)$$

1A point module over $A$ is a graded right $A$-module generated in degree zero with Hilbert function $1, 1, 1, 1, 1, \ldots$. There is a 1-1 correspondence between points in $Y$ and point modules over $A$. See [2].
where

\[ \mathcal{O}_X \otimes_{\mathcal{O}_Y} m_{\sigma^2 m - n + n_d} = \ker(\mathcal{O}_X \to \mathcal{O}_{\sigma^2 m - n + n_d}) \]

Thus \( \mathcal{O}_X \otimes_{\mathcal{O}_Y} m_{\sigma^2 m - n + n_d} \) is of the form \( \pi(\ker A \to M) \) with \( M \) as in Lemma 6.1. We conclude that we have a resolution of \( (a)D_{m,m+1} \) of the form

(6.1) \[ 0 \to \mathcal{O}_X(a - 1)^{\oplus 2} \to \mathcal{O}_X(a)^{\oplus 3} \to (a)D_{m,m+1} \to 0 \]

This resolution is actually of the form

(6.2) \[ 0 \to \mathcal{O}_X(a - 1)^{\oplus 2} \to \mathcal{O}_X(a) \otimes_k D_{m,m+1} \to (a)D_{m,m+1} \to 0 \]

In the cubic case the resolution will follow from the next lemma:

**Lemma 6.2.** Let \( A \) be a cubic AS-regular algebra of dimension 3. Let \( p \) be a point in \( Y \) and let \( P \) be the corresponding point module. Then there is a complex of the following form:

(6.3) \[ 0 \to A(-5) \overset{\zeta,0}{\to} A(-4)^{\oplus 2} \oplus A(-3) \to A(-2)^{\oplus 3} \to A \to P \to 0 \]

where \( \zeta \) is part of the minimal resolution of \( k \) as given in [1, Theorem 1.5.]

\[ 0 \to A(-4) \overset{\zeta}{\to} A(-3)^{\oplus 2} \overset{\xi}{\to} A(-1)^2 \overset{\delta_0}{\to} A \overset{\gamma}{\to} k \to 0 \]

Moreover the complex (6.3) is exact everywhere except at \( A \) where it has one-dimensional cohomology, concentrated in degree one.

**Proof.** From [2, Proposition 6.7.] we know \( P \) has the following (minimal) resolution:

\[ 0 \to A(-3) \to A(-2) \oplus A(-1) \to A \to P \to 0 \]

Combining this with the minimal resolution for \( k \) we get the following diagram
Put $\delta = \delta_0 \oplus \text{id}$. The existence of the map $\eta$ such that $\delta \circ \eta = \alpha$ follows from the projectivity of $A(-3)$ and the fact that $\gamma \circ \alpha$ is zero by degree reasons. By diagram chasing one easily finds that $\ker(\beta \circ \delta) = \text{im}(\varepsilon) \oplus \text{im}(\eta)$ and hence we end up with the following complex:

$$0 \to A(-5) \xrightarrow{\xi,0} A(-4) \oplus A(-3) \xrightarrow{\eta,\zeta} A(-2) \oplus A \xrightarrow{\eta,\delta} A \xrightarrow{\eta} P \to 0$$

Using diagram chasing again one easily checks that this complex is exact everywhere except at $A$. We then conclude with a Hilbert series argument. \(\square\)

In a similar way as in the quadratic case we conclude that $(a)\mathcal{D}_{m,m+1}$ has a resolution of the form

$$(6.4) \quad 0 \to \mathcal{O}_X(a-3) \xrightarrow{(\zeta,0)} \mathcal{O}_X(a-2) \oplus \mathcal{O}_X(a-1) \to \mathcal{O}_X(a) \to (a)\mathcal{D}_{m,m+1} \to 0$$

which is actually of the form

$$(6.5) \quad 0 \to \mathcal{J}(a) \oplus \mathcal{O}_X(a-1) \to \mathcal{O}_X(a) \otimes_k \mathcal{D}_{m,m+1} \to (a)\mathcal{D}_{m,m+1} \to 0$$

where

$$(6.6) \quad \mathcal{J} \overset{\text{def}}{=} \text{coker}(\mathcal{O}_X(-3) \xrightarrow{\zeta} \mathcal{O}_X(-2) \oplus)$$

We will now prove some vanishing results. An object in $\text{Qch}(X)$ will be said to have finite length if it is a finite extension of objects of the form $\mathcal{O}_p, p \in Y$. Likewise an object in $\text{Bimod}(X - X)$ will be said to have finite length if it is a finite extension of $\mathcal{O}_p$ for $p \in Y$. The objects of finite length are fully understood, see [22, Chapter 5]. Note that by [22, Proposition 5.5.2] $o_p$ is a simple object in $\text{Bimod}(X - X)$ so the Jordan-Holder theorem applies to finite length bimodules.

**Lemma 6.3.** A finite length object in $\text{Qch}(X)$ has no higher cohomology.

*Proof.* For an object of the form $o_p$ this follows from [22, Proposition 5.1.2] with $\mathcal{F} = \mathcal{O}_X$. The general case follows from the long exact sequence for $\text{Ext}$.

\(\square\)

**Lemma 6.4.** $H^2(X, (-l)\mathcal{D}_{m,n}) = 0$ for $l \leq 2n - 2m + s$.

*Proof.* We only need to consider the case $n \geq m$. This follows from the fact that $(-l)\mathcal{D}_{m,n} \subset \mathcal{O}_X(2n - 2m - l)$ with finite length cokernel and from the standard vanishing properties on $\text{QGr}(A)$ (see for example [5, Theorem 8.1]).

\(\square\)

**Lemma 6.5.** $H^1(X, (a)\mathcal{D}_{m,n}) = 0$ for $a \geq -s + 1$.

*Proof.* We only need to consider the case $n \geq m$. The proof for $a \geq -1$ is similar in the cases $(r,s) = (2,3)$ and $(r,s) = (3,2)$ so we will give the proof for the first case as it is slightly longer. Afterwards we will consider the case $(r,s) = (2,3)$ and $a = -2$.

Suppose $(r,s) = (2,3)$ and $a \geq -1$. We prove $H^1(X, (a)\mathcal{D}_{m,n}) = 0$ by induction on $n - m$. As $(a)\mathcal{D}_{m,m} = \mathcal{O}_X(a)$ the base case follows from the standard vanishing on $X$.

For the induction step we proceed as follows: From [22, Theorem 5.5.10] and the fact that $\mathcal{D}_{m,n} \subset o_X(2n - 2m)$ with finite length cokernel we may deduce that the kernel of the obvious surjective map

$$\mathcal{D}_{m,m+1} \otimes_{\mathcal{O}_X} \mathcal{D}_{m+1,n} \to \mathcal{D}_{m,n}$$
has finite length. Using [22, Lemma 8.2.1] we see that this remains the case if we left tensor with \( \mathcal{O}_X(a) \). Thus we obtain a short exact sequence in \( \text{Qch}(X) \)

\[
0 \rightarrow \text{f.l.} \rightarrow (a)D_{m,m+1} \otimes_X D_{m+1,n} \rightarrow (a)D_{m,n} \rightarrow 0
\]

from which we find \( H^1(X,(a)D_{m,n}) = H^1(X,(a)(D_{m,m+1} \otimes_X D_{m+1,n})) \) by Lemma 6.3. From (6.5) we obtain an exact sequence

\[
\tag{6.7} \text{Tor}_1^{\mathcal{O}_X}((a)D_{m,m+1}, D_{m+1,n}) \rightarrow J(a) \otimes_X D_{m+1,n} \oplus (a - 1)D_{m+1,n} \rightarrow \quad
\]

\[
D_{m,m+1} \otimes_k (a)D_{m+1,n} \rightarrow (a)D_{m,m+1} \otimes_X D_{m+1,n} \rightarrow 0
\]

One deduces again, for example using [22, Theorem 5.5.10], that \( \text{Tor}_1^{\mathcal{O}_X}((a)D_{m,m+1}, D_{m+1,n}) \) has finite length. It is clear that \( (a - 1)D_{m+1,n} \) has no finite length subobjects. We claim this is the same for \( J(a) \otimes_X D_{m+1,n} \). Indeed tensoring the short exact sequence

\[
0 \rightarrow J(a) \rightarrow \mathcal{O}_X(a) \otimes \mathcal{O}_X \rightarrow \mathcal{O}_X(a+1) \rightarrow 0
\]

on the right with \( D_{m+1,n} \) and using Tor-vanishing [22, Theorem 8.2.1] we obtain a short exact sequence

\[
\tag{6.8} 0 \rightarrow J(a) \otimes_X D_{m+1,n} \rightarrow (a)D_{m+1,n} \otimes (a + 1)D_{m+1,n} \rightarrow 0
\]

Hence in particular \( J(a) \otimes_X D_{m+1,n} \subset (a)D_{m+1,n} \) is torsion free. We conclude that (6.7) becomes in fact a short exact sequence

\[
\tag{6.9} 0 \rightarrow J(a) \otimes_X D_{m+1,n} \oplus (a-1)D_{m+1,n} \rightarrow D_{m,m+1} \otimes_k (a)D_{m+1,n} \rightarrow (a)D_{m,m+1} \otimes_X D_{m+1,n} \rightarrow 0
\]

We find that \( H^1(X,(a)(D_{m,m+1} \otimes_X D_{m+1,n})) \) is sandwiched between a direct sum of copies of \( H^1(X,(a)D_{m+1,n}) \) (= 0 by the induction hypothesis) and a direct sum of copies of \( H^2(X,J(a) \otimes_X D_{m+1,n}) \). Now \( H^2(X,J(a) \otimes_X D_{m+1,n}) \) is trivial as well because it is sandwiched between a direct sum of copies of \( H^2((a-2)D_{m+1,n}) \) (= 0 by Lemma 6.4) and \( H^3(X,(a-3)D_{m+1,n}) \) (= 0 as \( H^3(X,-) = 0 \)).

We now prove \( H^1(X,(-2)D_{m,n}) = 0 \) when \( (r,s) = (2,3) \). This can also be done by induction on \( n - m \). The case \( n = m \) again follows from the standard vanishing on \( X \). For the induction step recall that for any point \( q \) there is an exact sequence:

\[
0 \rightarrow \mathcal{O}_X(-3) \rightarrow \mathcal{O}_X(-2) \oplus \mathcal{O}_X(-1) \rightarrow \mathcal{O}_X \otimes_X m_q \rightarrow 0
\]

Applying \( - \otimes_X D_{m+1,n} \) yields an exact sequence

\[
0 \rightarrow (-3)D_{m+1,n} \rightarrow (-2)D_{m+1,n} \oplus (a-1)D_{m+1,n} \rightarrow \mathcal{O}_X \otimes_X m_q \otimes_X D_{m+1,n} \rightarrow 0
\]

where the injectivity of \( (-3)D_{m+1,n} \rightarrow (-2)D_{m+1,n} \oplus (a-1)D_{m+1,n} \) is a torsion/torsion free argument as above in the derivation of (6.9). In particular we can consider a long exact sequence of cohomology groups. As in this sequence \( H^1(X,(-2)D_{m,n}) = H^1(X,m_{r-m-1,p} \otimes_X D_{m+1,n}) \) is sandwiched between \( H^1(X,(-2)D_{m+1,n}) \) and \( H^1(X,(-3)D_{m+1,n}) \) we can conclude by the induction hypothesis, the case \( a \geq -1 \) which was already done and Lemma 6.4.

We may now draw some conclusions.

**Lemma 6.6.** \( D \) is generated in degree one.
Hence we must show that the leftmost arrow is zero.

Similarly in the cubic case the colength of $p$ follows from Lemma 6.5. For the second of these claim we invoke the definition (6.6). It follows that we have to show

$$\dim D_{m,m+1} = \frac{(a+1)(a+2)}{2}$$

Using the fact that $H^1(X, \mathcal{D}_{m,n}) = 0$ by Lemma 6.5 we obtain (for $a \geq 0$)

$$\dim D_{m,m+a} = \frac{(2a+1)(2a+2)}{2} - \frac{3(a+1)}{2} = \frac{(a+1)(a+2)}{2}$$

Similarly in the cubic case the colength of $\mathcal{D}_{m,m+a}$ inside $o_X(2a)$ is

$$\frac{a(a+1)}{2}$$

and again using the fact that $H^1(X, \mathcal{D}_{m,n}) = 0$ we obtain (for $a \geq 0$)

$$\dim D_{m,m+a} = \frac{(2a+2)^2}{4} - \frac{a(a+1)}{2} = \frac{(a+1)(a+2)}{2}$$

Hence in both cases (6.10) holds.

Finally we prove the following.

\textbf{Lemma 6.7.} The canonical map $D \to D_Y$ is surjective.
Proof. As $D$ and $D_Y$ are both generated in degree 1 (for $D_Y$ this is proved in the same way as for $B(Y, \sigma, \mathcal{L})$, see [3]), it suffices to check that $D_{m,m+1} \to (D_Y)_{m,m+1}$ is surjective. For this consider the following commuting diagram (with $\mathcal{O}_X(-Y) = \mathcal{O}_X \otimes_{o_X} o_X(-Y)$ the subobject of $\mathcal{O}_X$ correspoding to the ideal $gA \subset A$)

\[
\begin{array}{ccccc}
0 & 0 & 0 \\
\mathcal{O}_X(-Y) & \mathcal{O}_X \otimes_X m_d & \mathcal{O}_X \otimes_X m_{d,Y} & \\
0 & \mathcal{O}_X(-Y) & \mathcal{O}_X & \mathcal{O}_Y & 0 \\
0 & 0 & \mathcal{O}_d & \mathcal{O}_d & 0 \\
0 & 0 & 0 & 0 & 0
\end{array}
\]

The bottom two rows and the first column are obviously exact. The third column is equal to

$$0 \to M_{d,Y} \to \mathcal{O}_Y \to \mathcal{O}_d \to 0$$

and hence is exact. The exactness of the middle column follows as usual from [22, Lemma 8.2.1]. Hence we can apply the Snake lemma to the above diagram and find the following exact sequence:

$$0 \to \mathcal{O}_X(-Y) \to \mathcal{O}_X \otimes_X m_d \to \mathcal{O}_X \otimes_X m_{d,Y} \to 0$$

As the above obviously remains true when we replace $d$ by $\sigma^{-m}d$ and as $o_X(2)$ is an invertible bimodule we get an exact sequence

$$0 \to \mathcal{O}_X(-Y) \otimes_X o_X(2) \to \mathcal{O}_X \otimes_X D_{m,m+1} \to \mathcal{O}_X \otimes_X (D_Y)_{m,m+1} \to 0$$

The surjectivity of $D_{m,m+1} \to (D_Y)_{m,m+1}$ then follows from $H^1(X, \mathcal{O}_X(-Y) \otimes_X o_X(2)) = H^1(X, \mathcal{O}_X(-1)) = 0$ using that $o_X(-Y) = o_X(-3)$ (see §4) as well as the standard vanishing results for $X$ (see [5, Theorem 8.1]).

Since now the map $D \to D_Y$ is surjective, one checks using (6.10) that $D_{m,n} \to D_{Y,m,n}$ is an isomorphism for $n \leq m + 2$. Thus $D$ and $D_Y$ have the same quadratic relations. Let $D'$ be the quadratic AS-regular $\mathbb{Z}$-algebra associated to $(Y, \mathcal{L}_0, \mathcal{L}_1)$ (see §2). Then since $D'$ is quadratic, and has the same quadratic relations as $D_Y$ we obtain a surjective map $D' \to D$. Since $D'$ and $D$ have the same Hilbert series by (6.10) we obtain $D' \cong D$. Hence $D$ is the quadratic AS-regular $\mathbb{Z}$-algebra associated to $(Y, \mathcal{L}_0, \mathcal{L}_1)$. 

\[\square\]
7. Non-commutative function fields

As above let $A$ be a 3-dimensional Sklyanin algebra, which may be either quadratic or cubic, with geometric data $(Y, \sigma, \mathcal{L})$ and let $D$ be the AS-regular $\mathbb{Z}$-subalgebra of $\tilde{A}^{(2)}$ constructed in §4.

Let $A'$ be the 3-dimensional quadratic Sklyanin algebra with geometric data $(Y, \sigma, \mathcal{L}_0)$ if $A$ is quadratic and $(Y, \psi, \mathcal{L}_0)$ if $A$ is cubic where $(\mathcal{L}_i)_i$ is as in (5.2).

By the discussion at the end of §2 together with Lemma 5.1 we conclude that $D \cong \tilde{A}'$.

We will now show that there is an isomorphism between the function fields of $\text{Proj } A$ and $\text{Proj } A'$. In the case that $A$ is cubic this will be the final step in the proof of Theorem 1.1. If $A$ is quadratic then the relation between $A$ and $A'$ is a generalization of the classical Cremona transform.

By the graded version of Goldie’s Theorem [11, Corollary 8.4.6.] the non-zero homogeneous elements of $A$ form an Ore set $S$ and hence the graded field of fractions $A[S^{-1}]$ of $A$ exists. By the structure theorem for graded fields [12] it is of the form

$$\text{Frac}(A) = \text{Frac}_0(A)[t, t^{-1}, \alpha]$$

where $\text{Frac}_0(A)$ is a division algebra concentrated in degree zero, $|t| = 1$ and $\alpha$ is an automorphism $\alpha : \text{Frac}_0(A) \to \text{Frac}_0(A) : a \mapsto tat^{-1}$. $\text{Frac}_0(A)$ was introduced in the introduction as “the function field” of $\text{Proj } A$. Our aim is to show that $\text{Frac}_0(A) \cong \text{Frac}_0(A')$.

It is straightforward to generalize the concept of an Ore set and its corresponding localization to $\mathbb{Z}$-algebras. In fact this is the classical concept of an Ore set in a category (and its corresponding localization).

If $S \subset A$ is a multiplicative closed Ore set consisting of homogeneous elements then one defines a corresponding multiplicative closed Ore set $\tilde{S} \subset \tilde{A}$ by putting $\tilde{S}_{ij} = S_{j-i}$. A straightforward check yields $\tilde{A}[S^{-1}] \cong \tilde{A}[\tilde{S}^{-1}]$.

Now let $S$ and $S'$ be the set of nonzero homogeneous elements in $A$ respectively $A'$. Then the inclusion $A' \hookrightarrow \tilde{A}^{(2)} \hookrightarrow \tilde{A}$ restricts to $S' \hookrightarrow \tilde{S}$ and hence for arbitrary $i \in \mathbb{Z}$ there is an induced map $\zeta_i$:

$$\text{Frac}_0(A') = (\text{Frac}_0(A)[S'^{-1}])_0 \cong (\tilde{A}[\tilde{S}^{-1}])_i \to (\tilde{A}[\tilde{S}^{-1}])_{2i} \cong (A[S^{-1}])_0 = \text{Frac}_0(A)$$

Although this map depends on $i$ we will show that it is always an isomorphism.

As $\text{Frac}_0(A')$ and $\text{Frac}_0(A)$ are division rings and $\zeta_i \neq 0$, it follows that $\zeta_i$ is always injective, so the only nontrivial thing to do is proving its surjectivity. So given any $a, s \in \tilde{A}_{2i,2j} \setminus \{0\}$ we need to find a $j_2 \in \mathbb{Z}$ and $h \in \tilde{A}_{2j_1,2j_2}$ such that $ah, sh \in A'_{i,j_2}$. We claim we can find such an $h$ only depending on $n := j_1 - i$ and not on $a$ or $s$. For this consider the following map:

$$\Gamma(X, o_X(2n)) \otimes \Gamma(X, o_X(2n) \otimes_X \mathcal{I}) \to \Gamma(X, o_X(2(n + N) \otimes_X \mathcal{I}))$$

where $\mathcal{I}$ is the ideal in $o_X$ such that $o_X(2(n + N)) \otimes_X \mathcal{I} = D_{t_1,t_1+n+N}$ (see (4.5)).

If we can choose an $N$ such that

$$\dim_k \Gamma(X, o_X(2N) \otimes_X \mathcal{I}) \neq \{0\}$$

then there is an element $0 \neq h \in \tilde{A}_{2i+2n,2i+2n+2N}$ and an embedding

$$\tilde{A}_{2i,2i+2n} \hookrightarrow A'_{i,i+n+N} : a \mapsto ah$$
which yields the surjectivity of \( \text{Frac}_0(A') \to \text{Frac}_0(A) \) (as we may take \( j_2 = j_1 + N = i + n + N \) in the above). So it suffices to prove (7.1). As the cases \((r, s) = (3, 2)\) and \((r, s) = (2, 3)\) are completely similar, we only treat the first case.

Note that the codimension of \( \Gamma(X, \mathcal{O}_X(2N)) \) inside \( \tilde{A}_{2i_1 + 2n, 2i + 2n + 2N} \) is at most \( 3\frac{N(N+1)}{2} \) which grows like \( \frac{3N^2}{2} \). On the other hand \( \dim_k(\tilde{A}_{2i_1 + 2n, 2i + 2n + 2N}) = \frac{(2N+1)(2N+2)}{2} \) which grows like \( 2N^2 \), so for \( N \) sufficiently large (7.1) will be fulfilled.

8. Relation with non-commutative blowing up

For the interested reader we now sketch how the \( \mathbb{Z} \)-algebra \( D \) which was introduced in a somewhat ad hoc manner in §4 may be obtained in a natural way from the formalism of non-commutative blowing up as introduced in [22].

First let us remind the reader how the commutative Cremona transform works. Let \( p_1, p_2, p_3 \in \mathbb{P}^2 \) be three distinct non-collinear points on \( \mathbb{P}^2 \) and consider the linear system of quadrics passing through those points. This is a \( 5 \times 3 = 2 \) dimensional linear system and hence it defines a birational transformation \( \phi : \mathbb{P}^2 \to \mathbb{P}^2 \) with \( \{p_1, p_2, p_3\} \) being the points of indeterminacy.

The indeterminacy of \( \phi \) may be resolved by blowing up the points \( \{p_1, p_2, p_3\} \). Let \( \alpha : \tilde{X} \to \mathbb{P}^2 \) be the resulting surface and let \( L_1, L_2, L_3 \) be the exceptional curves. Then the Cremona transform factors as

\[
\begin{array}{c}
\mathbb{P}^2 \\
\phi \downarrow \\
\mathbb{P}^2
\end{array}
\begin{array}{c}
\tilde{X} \\
\alpha \downarrow \\
\mathbb{P}^2
\end{array}
\]

where the right most map is obtained from the sections of the line bundle \( \mathcal{O}_\tilde{X}(1) = \alpha^*(\mathcal{O}_{\mathbb{P}^2}(2)) \otimes \tilde{X} \mathcal{O}_X(-L_1 - L_2 - L_3) \) on \( \tilde{X} \).

Now we replace \( \mathbb{P}^2 \) by the non-commutative \( \mathbb{X} \) given by \( \text{Proj} A \) where \( A \) is a 3-dimensional quadratic Sklyanin algebra. We will use again the standard notation \( Y, \mathcal{L}, \sigma, p_1, p_2, p_3, d, \ldots \). According to [22] we may blow up \( \mathbb{P}^2 \) \( \mathbb{X} \) in \( d \) to obtain a map of non-commutative schemes \( \alpha : \tilde{X} \to X \). Then we need a substitute for the line bundle \( \mathcal{O}_\tilde{X}(1) \) on \( \tilde{X} \). Actually in the non-commutative case it is more natural to look for a substitute for the family of objects \( (\mathcal{O}_\mathbb{X}(n))_\mathbb{X} \) since then there is an associated \( \mathbb{Z} \)-algebra

\[
\bigoplus_{m,n} D_{m,n} = \bigoplus_{m,n} \text{Hom}_\mathbb{X}(\mathcal{O}_\mathbb{X}(-n), \mathcal{O}_\mathbb{X}(-m))
\]

This idea has been used mainly in the case that the sequence is ample in a suitable sense (e.g. [13]), but the associated \( \mathbb{Z} \)-algebra may be defined in general. Of course in the non-ample case the relation between the sequence and the underlying non-commutative scheme will be weaker.

Let us now carry out this program in somewhat more detail. According to [22] we have \( \tilde{X} = \text{Proj} D \) where \( D \) is a graded algebra in \( \text{Bimod}(\mathbb{X} - \mathbb{X}) \) given by

\[
ono_X \oplus m_d(Y) \oplus m_d m_{-1}d(2Y) \oplus \cdots \oplus m_d \cdots m_{-n+1}d(nY) \oplus \cdots
\]

The inclusion \( \mathcal{O}_X \to D \) yields the map \( \alpha : \tilde{X} \to X \).  

\footnote{In [22] we discuss the case of a blowup of a single point. Blowing up a set of points is similar.}
Suitable noncommutative analogue of the objects $O_X(-mL_1 - mL_2 - mL_3)$ turn out to be the objects in $\text{Bimod}(X - \tilde{X})$ associated to the $O_X - \mathcal{D}$-bimodules given by

$$m_{\tau + d} \otimes m_{\tau + m_{\tau + d}} \otimes m_{\tau - 1} \otimes m_{\tau - m_{\tau - 1} + d}(2Y) \otimes \cdots \otimes m_{\tau - n + 1} \otimes (nY) \otimes \cdots$$

Up to right bounded $O_X - \mathcal{D}$-bimodules (which are invisible in $\text{Proj}$) these are the same as

$$(O_X(-mY) \otimes X \mathcal{D})[m]$$

where $[1]$ is the shift functor on $\mathcal{D}$-modules (or bimodules, or variants thereof). So the non-commutative analogues of the objects $O_X(n)$ turn out to be associated to

$$(O_X(2n - nY) \otimes X \mathcal{D})[n]$$

where we have written $O_X(a + bY)$ for $O_X(a) \otimes X O_X(bY)$. Or ultimately

$$O_X(n) = \alpha^*(O_X(2n - nY))[n]$$

We now compute (the fourth equality requires an argument similar to [22, Proposition 8.3.1(2)])

$$D_{m,n} = \text{Hom}_X(O_X(-n), O_X(-m))$$
$$= \text{Hom}_X(\alpha^*(O_X(-2n + nY))[n], \alpha^*(O_X(-2m + mY))[m])$$
$$= \text{Hom}_X(O_X(-2n + mY), \alpha_*(\alpha^*(O_X(-2m + mY))[n - m]))$$
$$= \text{Hom}_X(O_X(-2n + nY), O_X(-2m + mY) \otimes_{O_X} D_{n-m})$$
$$= \text{Hom}_X(O_X(-2n), O_X(-2m) \otimes m_{\tau - m_{\tau - d}} \otimes m_{\tau - n + 1} \otimes (2n))$$
$$= \Gamma(X, O_X(-2m) \otimes m_{\tau - m_{\tau - d}} \otimes m_{\tau - n + 1} \otimes O_X(2n))$$

Hence we find indeed the same result as in §4.
