Welcome

On behalf of The European College of Sport Science (ECSS) and the Norwegian School of Sport Sciences (NSSS), I am delighted to welcome you to Oslo for the 14th annual ECSS Congress.

The Congress theme is 'Sport Sciences: Nature, Nurture and Culture'. Sport is a complex phenomenon that includes most dimensions of human life. The complete study of human activity in sport must build on a diversity of scientific approaches. The 14th Annual Congress programme feature theoretical, applied and cross-diosciplinary sport studies as well as research findings based on the natural, behavioural, social and human scientific disciplines.

The scientific programme is composed of more than 1.400 abstracts which were accepted after careful review by the scientific committee of the ECSS and the local scientific committee of the NSSS. The strong interest in this year's Congress underlines the growth and increasing significance of the ECSS as an interdisciplinary forum for ongoing debate. The presented abstracts comprise not only all relevant sport science subdisciplines and themes but also all continents and 79 different nations. The abstracts are distributed among four Plenary Sessions, 36 Invited Symposia, 74 Oral Sessions, and four Poster Sessions with more than 870 posters.

Oslo is the capital of Norway and is situated at the head of Oslo fjord surrounded by forested ridges. The city is unique, a city surrounding a sea inlet with mountains as a backdrop. Apart from the scientific programme features, I encourage you to enjoy Oslo and take advantage of our social programme with various sight seeing options, exercise and training possibilities and a closing banquet in the beautiful natural surroundings of the NSSS.

On behalf of the ECSS and the Oslo team I wish you all a pleasant and productive stay in Oslo!

Sigmund Loland

THE EFFECT OF EXHAUSTIVE EXERCISE ON IGA AND TNF A

NAMENI, F., GAIENII, A.A.

AZAD ISLAMIK UNIVERSITY , VARAMIN

Introduction: In vivo depletion of lymphocyte subsets allows investigation of the role of specific subsets in protective immunity. Immune cells are potent intracellular that regulate inflammation and immune response . The others have shown that exercise causes changes in specific types of immune components .The changes depend on duration and intensity of exercise . This study examined the effect of exhausting exercise on the IgA and TNFα .

Method: 20 recreational active women , volunteered for this study . Who were normal healthy , with no positive clinical finding . After having the procedures fully explained to them written information consent . Height (162.81±3.982 cm) ,weight (56.11± 5.79 kg) , BMI (21.74± 1.99 kg/h2) , and body fat (23.12±.57 %) of them measured , later subjects performed exhaustive exercise . Protocol exercise was an incremental treadmill(Bruce protocol) . Blood sampling were obtained before and after exercise and were drawn from an anticubital vein with subjects in the seated position . Paired t -test were used to determine before versus after exercise differences , α was set at 0/05. Data are presented as mean ± ME of the mean .

Results: The concentration of IgA increased and were significant , but TNFα concentration ,not changed (P ≤ 0 / 05).

Discussion: The effect of exhaustive exercise on subjects was significant that may be transient and related with intensity and duration. The results suggest that the exhaustive exercise induced changes in lymphocyte subsets but may not induced suppression immune function .

THE ALTERATION OF SOME IMMUNE SYSTEM FACTORS AFTER SIXTEEN SESSIONS OF PHYSICAL EXERCISE

POURVAGHAR, M.J., SHAHSAVAR, A.R.

1. UNIVERSITY OF KASHAN, 2. ISLAMI AZAD UNIVERSITY OF TEHRAN GHARB

The aim of this research was to examine the effects of regular running during 16 sessions on alteration in serum immunoglobulins including IgA, IgG and IgM. To this end, 12 male students participated in this semi-experimental research. The obtained average and standard deviations of factors such as age, height, weight and body mass index (BMI) are as follows: (22.1 ± 1.60), (175.2 ± 3.55), (70.51 ± 3.6) and (22.4 ± 2.1). The subjects were trained according to a running plan with a certain heart rate during 16 sessions. To determine the amount of serum immunoglobulins, the participants' blood samples were taken once before the first running session and a second time the day after the last training session. Also, a 12-minute running-walking test was performed to determine the Maximal Oxygen Consumption (VO2 Max).

In this study, the mean of the subjects' exercise time was 18.30 minutes and it seems that this time can not affect the immune system and its function. Also, the time allocated to training regarding the response from serum immunoglobulins is a determining factor in a way that the concentration alteration of serum immunoglobulins after 2 hours of pedaling was measured in an article. Another issue is the frequency of exercise sessions per week. The researches leading to a change in immunoglobulins result from more exercise sessions per week and even during one competition season.

LYMPHOCYTES APOPTOSIS INDUCED BY MARATHON RACE IN ATHLETES

CURY-BOAVENTURA, M.F., ALVES, S.R., MARQUES, C.C., CONEGLIAN, V.S., LEVADA-PIRES, A.C., PITHON-CURI, T.C., CURI, R.

INSTITUTE OF PHYSICAL ACTIVITY AND SPORTS, CRUZEIRO DO SUL UNIVERSITY

Introduction: Physiological Stress induced by marathon race is able to promote transient changes on immune function. Post-exhaustive exercise of immunosuppression is characterized by a decrease in number of leukocytes, suppression of natural killer (NK) cell activity, and lymphocyte proliferation. Recent studies have been suggested that the role of leukocyte death on immunossupression is induced by exercise. Objective: Lymphocyte function and death, after a race was investigated. Methods: Nine athletes (training 170 + 15 km/wk, body fat, 6,5 + 1,7 %, race time 2h 46 + 11 min; IMC: 21,5 + 0,4) and eight non-athletes volunteers were recruited. Athletes blood samples were collected (3-7 days before, on rest) and immediately after the marathon race (42,195 km, Curitiba, Brazil). Non-athlete's blood samples were collected on rest periods. Lymphocytes were isolated by density gradient, using Histopaque-1077 and studied immediately after

isolation, or after 18h ConA stimulation. The following determinations were carried out: lymphocyte proliferation, parameters of lymphocyte death (viability, DNA fragmentation, phosphatidylserine externalization, mitochondrial depolarization) and TNF-alpha, IL-1beta and IL-10 production. Results: Marathon race had no effect on lymphocyte proliferation, viability and mitochondrial membrane polarization, but increased phosphatidylserine externalization (35 %) and reduced by 70 % TNF-alpha, IL-1 beta and IL-10 production, compared with athletes before race and non-athletes volunteers. Conclusion: Marathon race induced lymphocytes death in athletes volunteers predominantly by apoptosis, and reduced pro and anti-inflammatory cytokine production. These facts may contribute to the hypothesis that endurance exercise induce immunosuppression and raise incidence of upper tract respiratory infection in athletes.

CORRELATION BETWEEN SALIVALRY AND SERUM CORTISOL CONCENTRATION AFTER ONE SESSION SEVER ENDURANCE AND RESISTANCE ACTIVITY IN WOMEN

PARIAD, M., HASANLOUI, H., GOLI VARJOEI, M.

1. ISLAMIC AZAD UNIVERSITY, 2. CENTER FOR SENSORY-MOTOR INTRACTION,DEPARTMENT OF HELTH SIENCE AND TECHNOLOGY, AALBORG UNIVERSITY ,AALBORG, DENMARK

Introduction: Measuring of stroeidal hormone which play an important role in metabolism regulating,specially during physical activities,has been remarkable for the researchers.a good correlation has been reported between amounts of salivarly and serum cortisol in exercise and clinical situation.but the results showed that there are some conflicts between salivarly and serum cortisol correlation.so,if we obtain a significant relation between salivarly and serum cotisol after strength and endurance training,we can obtain a better understanding of the hormone responces to physical activities.therefore,the aim of this study was to investigate the relation between salivary and serum cortisol concentration after resistance and endurance exercise protocol.

Metods: Twenty subjects (23.03±1.5yr,weight 63.88±5.88,height 168.69±6.63 kg)randomly divided into two group.endurance group participate in endurance protocol(Bruce test) and resistance group participate in resistance protocol(3 exercise,5sets×10 repetitions at 70%1RM with 3 min rest between sets).samples of salivary and serum cortisol were collected befor and immediately after both exercise protocol,and were measured using the spetial RADIM kits.data obtained from the assessing of the samples were analyzed using the statistical T-test and Pierson correlation (R). P≤0.05 was considered as the significant level.

Results: The result of this study showed that salivary and serum cortisol concentration increased in two group following both exercise protocol.and the rate of increases in salivary cortisol in both group was more than in serum cortisol concentration.and there is significant correlation between salivary and serum cortisol concentration in both group.

Discussion: We found a significant correlation between saliva and serum cortisol concentration after both exercise protocole,so this would suggest that salivary cortisol concentration might be a more suitable variable for assessing glucocorticoid activity in exercise than serum cortisol concentration,probably being less sensitive to pre-exercise emotional state.

THE EFFECTS OF 2-DAYS REPEATED COMPETITIVE STRESS ON SALIVA IMMUNOGLOBULIN-A RESPONSES IN TRAINED MALE ATHLETES

LAING, S., JACKSON, A.R., DJEDOVIC, N., CARDINALE, M.

OLYMPIC MEDICAL INSTITUTE

A decrease in the salivary concentration of immunoglobulin A (IgA) has been implicated as a possible causal factor in the increased susceptibility of athletes to upper respiratory tract infections (URTI). The aim of this investigation was to determine the effects of two days of competitive biathlon roller-ski racing upon s-IgA concentration and secretion rate, and salivary cortisol and testosterone concentrations. Five male athletes (mean ± SEM; age 25 ± 1 years; height 177 ± 2 cm; body mass 74 ± 2 kg; body fat 10 ± 1 %; VO2max 59 ± 2 ml.kg-1.min-1) volunteered to participate in this study. All athletes were members of the British national team. None of the athletes was taking medications and/or reported symptoms of infections in the 4 weeks prior to the study . On two consecutive days separated by 20 hours, athletes completed 2 biathlon roller ski races consisting or roller skiing and rifle shooting. Race 1 was a 9.3 km SPRINT race characterised by 3 x 3.1 km roller ski loops on an undulating course with 2 x rifle shooting (one lying in a prone position and one from a standing position). Race 2 was a 13 km PURSUIT race characterised by 5 x 2.6 km roller ski loops on an undulating course with 4 x rifle shooting (two lying in a prone position and two from a standing position). During rifle shooting athletes were required to hit five targets positioned at a distance of 50 meters. For every target missed athletes were required to complete a 200 meter penalty loop. Unstimulated whole saliva samples were collected pre- and post- SPRINT and PURSUIT races. Saliva was collected for 3 ± 0.25 minutes by the athlete leaning forward and passively drooling into pre-weighed polypropylene tubes with minimal orofacial movements The s-IgA, cortisol and testosterone concentrations were determined using sandwich-type ELISAs. Saliva IgA secretion rate was determined by multiplying the s-IgA concentration by saliva flow rate. Saliva flow rate increased post-SPRINT ($P < 0.01$) and post-PURSUIT ($P < 0.05$) races. Saliva IgA concentration decreased by 53 % following the SPRINT race ($P < 0.05$) and 47 % following the PURSUIT race. Saliva IgA secretion rate showed a trend to increase following both races however was not significant. Salivary cortisol concentration increased post-SPRINT and post-PURSUIT ($P < 0.01$) races whereas, salivary testosterone decreased post-SPRINT ($P < 0.01$) and increased post-PURSUIT race ($P < 0.05$). There was a strong correlation between salivary cortisol concentration and the percentage race time spent between 90-100 % HRmax (R2 0.71, $P < 0.01$) in the SPRINT race, and there was also a strong correlation between salivary cortisol concentration and the percentage race time spent between 80-89 % HRmax (R2 0.65, $P < 0.05$) in the PURSUIT race. These findings suggest that athletes undertaking repeated intensive competitions over consecutive days do not demonstrate a reduction in saliva flow rate or s-IgA secretion rate., Sympathetic stimulation does not appear to inhibit saliva flow rate and s-IgA output (secretion rate) shortly after the race.

THE EFFECT OF AEROBIC INTERVAL AND MAXIMAL STRENGTH TRAINING ON STROKE VOLUME IN CORONARY ARTERY DISEASE PATIENTS

KARLSEN, T.
NTNU TRONDHEIM

Background: High aerobic intensity endurance training is an effective means for improving peak oxygen uptake and endurance performance in coronary artery disease patients. The purpose of the present investigation was to study the effect of high aerobic intensity interval endurance training and maximal strength training upon peak stroke volume in coronary artery disease patients. Design: Eight coronary artery disease patients (age 61.4 +- 3.7 years) trained 30 interval training sessions with 4 x 4 minutes intervals at 85-95% of peak heart rate while ten coronary artery disease patients (age 66.5 +- 5.5 years) training 24 sessions of maximal horizontal leg press. In the interval training group peak stroke volume increased significantly by 23 % from 94.1 +- 23.0 mL. beat-1 to 115.8 +- 22.4 mL. beat-1 (p less than 0.05) from before to after training. Peak oxygen uptake increased significantly by 17 % from 27.2 +- 4.5 mL. kg-1 . min-1 to 31.8 +- 5.0 mL. kg-1 . min-1 (p less than 0.05) in the same group. No change was observed in peak stroke volume or oxygen uptake from before to after training in the maximal strength training group, despite a 35% improvement in submaximal walking performance. In the endurance training group a trend towards increased resting left ventricle ejection fraction was noted with increase in left ventricle ejection fraction from 62.3  6.5 to 65.4  7.2 % (p=0.06) from before to after training. Conclusion: High aerobic intensity interval training significantly improves peak oxygen uptake and peak stroke volume in coronary artery disease patients. Improved submaximal endurance after maximal strength training does not improve peak stroke volume or peak oxygen uptake in coronary artery disease patients.

GLUCOSE CONTROL WITH MINOR STRESS DURING RESISTANCE EXERCISE IN INDIVIDUALS WITH TYPE 2 DIABETICS

MOREIRA, S.R.
CATHOLIC UNIVERSITY OF BRASILIA

Introduction: Resistance and aerobic exercises has been proposed to treatment and/or control of diabetes (Albright, 2000), but there is a necessity to other investigations among different intensities for the glycaemia of diabetics. Therefore, the aim of this study was compare the effects of resistance exercise (RE) intensity on reducing blood glucose (GLUC) on type-2 diabetes (T2D) and healthy (NT2D) individuals.

Methods: Nine T2D (47.2±12.4 years; GLUC-179.6±70.1 mg.dL-1) and 10 NT2D (50.8±12.0 years; GLUC-80.3±14.9 mg.dL-1) performed: 1) a RE circuit (3 laps of ~25min) composed by Knee Extension, Bench-Press, Leg-Press, Pull-down, Knee Flexion and Seated Row, being 30 repetitions of 23% of one maximal repetition (1RM); 2) The same circuit but 16 reps x 43%1RM; and 3) Control session. Before each session the participants ingested a standard breakfast (285 kcal). Blood lactate (LAC) and GLUC were measured during exercise and at each 15min of the 120min of post-exercise recovery. Heart rate (HR), rate-pressure product (RPP) and rating perceived exertion (RPE) were also measured.

Results: The area under the curve (AUC) evidenced a significant effect of RE on reducing GLUC (mg.dL-1x145min) for 23%1RM (T2D - 12555.8±3268.9; NT2D - 10942.7±955.8) and 43%1RM (T2D - 13432.9±3054.4; NT2D -12156.2±1062.0) vs. Control (T2D - 14576.4±3922.2; NT2D -11498.2±881.9), $p<0.05$ for the intensities and among T2D e NT2D in control. Although that, the 43%1RM was more stressful than 23%1RM session ($p<0.05$) in both groups for LAC (T2D - 542.2±143.5 vs. 432.8±126.2 and NT2D - 615.0±148.7 vs. 479.0±144.1), RPP (T2D - 1691629.7±302358.8 vs. 1582176.0±188382.5 and NT2D - 1625613.3±295464.4 vs. 1506175.6±239996.0) and RPE (T2D - 384.7±64.6 vs. 323.9±62.5 and NT2D - 419.8±56.8 vs. 338.9±23.3).

Discussion: Resistance training for T2D is important for improvement of glycemic control, insulin sensitivity and muscular strength (Gordon, 2009). And one single session can provide transient improvements in glucose capitation. Our findings suggest that resistance exercise sessions performed at light and moderate intensities were effective on reducing blood glucose for T2D, with the 23%1RM session presenting a lower metabolic, hemodynamic and perceptual stresses.

INTRA-ARTERIAL BLOOD PRESSURE RESPONSE DURING RESISTANCE EXERCISE OF DIFFERENT INTENSITIES IN HYPERTENSIVES TREATED WITH ATENOLOL

FORJAZ, C.L.M., GOMIDES, R.S., SOUZA, D.R., COSTA, L.A.R., ORTEGA, K.C., FERNANDES, J.R.C., TINUCCI, T., MION JR, D.
UNIVERSITY OF SÃO PAULO

Introduction: Dynamic resistance exercise is recommended in association to aerobic exercise for hypertensive patients. Blood pressure increase during this kind of exercise is mainly due to an increase in peripheral vascular resistance; however, an increase in cardiac output might also be involved. This blood pressure increase seems to be exacerbated in non-medicated hypertensives when compared with normotensives. Nevertheless, most of the hypertensives are taking medications, and some of them are receiving β-blockers, which decreases cardiac output by the inhibition of sympathetic-induced increase on heart rate and cardiac contractility. Thus, β-blockers might decrease blood pressure rise during resistance exercise which, to our knowledge, has not been studied yet. Hence, the aim of this study was to verify the effects of the selective β-blocker atenolol on blood pressure increase during dynamic resistance exercise of different intensities.

Methods: Ten essential hypertensives with systolic/diastolic blood pressures under placebo condition maintained between 140 and 160 / 90 and 105 mmHg were recruited. These volunteers were studied after 6 weeks of placebo and atenolol treatment, and they were blinded for the medication used. In each phase, the volunteers executed, in a random order, 3 protocols of knee extension exercise until fatigue: a) 1 set at 100% of 1 repetition maximum (1RM); b) 3 sets at 40% of 1RM; and c) 3 sets at 80% of 1RM. Before, during and after the exercises, intra-arterial radial blood pressure was measured. Data were compared by paired student t-test and by two-way ANOVA for repeated measures. Newman-Keuls post-hoc test was applied when necessary. P≤0.05 was considered as significant.

Results: Atenolol decreased the absolute value achieved by systolic blood pressure during the exercise performed at the 3 intensities (maximum values: 100% = 186±4 vs. 215±7, 80%= 224±7 vs. 247±9 and 40% = 223±7 vs. 252±16, mmHg, P≤0.05). Moreover, atenolol also reduced systolic blood pressure increase in the first set of exercise at the 3 intensities (100% = +38±5 vs. +54±9; 80% = +68±11 vs. +84±13 and 40% = +69±7 vs. +84±14, mmHg, P≤0.05). In regard to diastolic blood pressure, atenolol decreased its

absolute values and its increase during exercise performed at 100% of 1RM (126±6 vs. 145±6 and +41±6 vs. +52±6, mmHg, P≤0.05), but it did not change diastolic blood pressure response at the other exercise intensities.

Conclusion:

Atenolol therapy was effective in reducing both systolic blood pressure absolute values and increase during resistance exercise of different intensities in hypertensive subjects; given them some cardiovascular protection. This result supports the hypothesis that cardiac output increase is important for blood pressure enhancement during this kind of exercise.

EFFECTS OF SHORT-TERM BODY-WEIGHT SUPPORTED TREADMILL TRAINING AND HEAD-UP TILT TRAINING ON HEART RATE DYNAMICS IN INDIVIDUALS WITH SPINAL CORD INJURY

MILLAR, P., RAKOBOWCHUK, M., ADAMS, M., HICKS, A., MCCARTNEY, N., MACDONALD, M.

MCMASTER UNIVERSITY

Increased risk of cardiovascular disease and autonomic disregulation are common health concerns in individuals with spinal cord injury (SCI) (Krassioukov and Claydon, 2006). Body-weight supported treadmill training (BWSTT) and head-up tilt training (HUTT) are two interventions that may help improve cardiovascular control in individuals with SCI. BWSTT has been shown to improve linear heart rate variability after 6 months of training in participants with SCI (Ditor et al., 2005), however, the effects of short-term training remain unknown. The purpose of this study was to compare the effects of short-term BWSTT and HUTT on neurocardiac regulation in SCI. Seven participants (6♂, 37.1 ± 7.7 yrs [mean ± SEM]) with SCI (lesion level: C5-T10, ASIA score: A-C; 5.0 ± 4.4 yrs post-injury) completed 4 wks of thrice-weekly BWSTT and HUTT (i.e. 12 sessions each), applied in a randomized, cross-over design, and separated by a 4 wk detraining period. Cardiac autonomic modulation was indirectly assessed at rest, before and after, each 4 wk training period using linear heart rate variability and non-linear (sample entropy and detrended fluctuation analysis (α1)) measures of heart rate dynamics. Participants completed equal amounts of BWSTT and HUTT (453.7 ± 27.3 min vs. 471.6 ± 19.7 min, p=0.24). There were no significant changes in any time or frequency indices of linear heart rate variability following either BWSTT or HUTT (p>0.05). A significant interaction effect (group x time) was detected for sample entropy as values increased following BWSTT (1.05 ± 0.14 to 1.57 ± 0.13, p<0.05) but not HUTT (1.36 ± 0.11 to 1.37 ± 0.17, p>0.05). The short-term scaling exponent (α1) exhibited a significant main effect for time (1.32 ± 0.10 to 1.17 ± 0.09, p=0.02), demonstrating an overall reduction following all training interventions. Due to the potential bidirectional responses of α1 we calculated a distance score from the value 1, which reflects healthy heart rate dynamics (Heffernan et al., 2008), defined as│1 – α1│. Following this calculation, a significant interaction effect was detected as BWSTT reduced the distance score (0.54 ± 0.06 to 0.26 ± 0.05, p=0.001), while no change was found after HUTT (0.36 ± 0.08 to 0.39 ± 0.09, p>0.05). In conclusion, 4 wks of BWSTT are sufficient to improve sample entropy and α1, but not traditional measures of linear heart rate variability. These improvements may reflect improved cardiac vagal modulation following short-term BWSTT. Further investigation is required to detail the potential effects of dynamic and passive training interventions on modulating non-linear heart rate dynamics in patients with SCI.

DECREASE IN HEART RATE AFTER LONGITUDINAL PARTICIPATION IN THE GRONINGEN ACTIVE LIVING MODEL (GALM) RECREATIONAL SPORTS PROGRAM

DE JONG, J.

HANZE UNIVERSITY OF APPLIED SCIENCES GRONINGEN

Objective: To investigate changes in heart rate during submaximal exercise as an index of cardiovascular function in older adults participating in the GALM recreational sports program who were sedentary or underactive at baseline.

Methods: A repeated measurement design was conducted; 151 participants were included, providing 398 heart rate files over a period of 18 months of GALM. Multilevel analyses were conducted; growth and final models containing a time variable and the covariates of sex, BMI, energy expenditure for recreational sports activities (EErecsport) and leisure-time physical activities (EEltpa) were developed.

Results: Significant decreases in mean heart rate over time appeared for all walking speeds. The covariates of sex and BMI were significantly related to mean heart rate at each walking speed, except for BMI at 7 km/h. No significant relations between EErecsport, EEltpa and mean heart rate occurred, except for EEltpa at 7 km/h. From baseline to T4, decreases in predicted mean heart rate were 5.5, 6.0, 10.0 and

9.0 beats/min at 4-, 5-, 6- and 7 km/h walking speeds; relative decreases ranged from 5.1 to 7.4%.

Conclusions: Significant decreases found in heart rate during submaximal exercise reflected a potential increase in cardiovascular function after 18 months of participation in GALM.

EFFECT OF VIGOROUS PHYSICAL ACTIVITY ON ARTERIAL STIFFNESS IN HIGH SCHOOL BOYS

MIURA, H.

LABORATORY FOR APPLIED PHYSIOLOGY

Introduction: Recently, the occurrence of life style-related such as hypertension, atherosclerosis, obesity, and hyperlipemia is increasing in young and old men. One of the reasons for this is lack of physical activity. Physical activity may play a pathophysiological role in the

development of atherosclerosis. Previous research reported that habitual exercise reduced arterial function in middle- to older aged men (Tanaka et al. 2000). However, few attempts have so far been made to identify the role of physical activity in arterial function on younger populations. Therefore, we tried to evaluate the influence of physical activity on arterial stiffness estimated by pulse wave velocity in high school students.

Methods: We studied 183 healthy high school boys aged 15 to 18 years (Height: 169.9±6.3cm; Weight: 63.1±10.2kg; %body fat: 14.6±5.8%). Subjects were divided into two groups: 83 were in the active group who participated in sports or athletic clubs in addition to physical education class and 100 were in the control group who were sedentary. The brachial systolic and diastolic blood pressure (SBP, DBP), and brachial to ankle pulse wave velocity (baPWV) were measured using a volume-plethymographic apparatus while in the supine position. In order to estimate the energy expenditure (EEA) during walking, moderate, and vigorous activities, the International Physical Activity Questionnaire with short format was adopted.

Results: In the active group, EEA during moderate and vigorous activities as well as the baPWV significantly differed from those in the control group (moderate-EEA: 87.3±94.1 vs. 37.5±38.2kcal/day; vigorous-EEA; 753.9±725.4 vs. 33.4±113.7kcal/day; baPWV: 1072.7±133.5 vs. 1150.6±162.7cm/sec, respectively). However, no significant differences of walking-EEA, of SBP, or of DBP were found between the active and control groups (walking-EEA: 5.4±9.5 vs. 8.9±13.9kcal/day; SBP: 124.7±10.2 vs. 124.7±10.1mmHg; DBP: 66.8±7.5 vs. 67.9±7.7mmHg, respectively). No significant correlation was found between all EEA and blood pressures. baPWV was significantly correlated to EEA during vigorous activity ($r=-0.27$, $p<0.05$).

Discussion: Compared with non-active boys, active high school boys have slower baPWV without any changes in blood pressure. Regular exercise increases the production of nitric oxide more and decreases endotheline-1 less (Maeda et al. 2001). The present results imply that these suggested effects are produced by greater physical activity. The level of physical activity influenced on arterial function in teenagers, which is agreement with previous results in middle- to older aged men (Seals 2003). From these results, spending more time performing vigorous physical activity has a favorable effect on arterial stiffness in teenagers as well as the elderly.

VALIDITY OF A WRIST-WORN ACCELEROMETER IN CHILDREN

EKBLOM, Ö., NYBERG, G., EKBLOM BAK, E., EKELUND, U., MARCUS, C.

SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES AND KAROLINSKA INSTITUTET

Introduction: Regular physical activity is a behaviour related to several positive health outcomes in children (Steele, RM, et al). However, the detailed relationships between activity and health outcomes have been hampered due to imprecise methodology, where intensity, type, frequency and duration of physical activity have been difficult to quantify. Furthermore, methodological shortcomings may have contributed to reduced contrast between physically "active" and "inactive" individuals and consequently an underestimation of the risks of physical inactivity. The aim of the present study was to assess the validity of a wrist worn accelerometer (Actiwatch) for estimating energy expenditure during various free-living activities and to determine cut-off values for light, moderate and vigorous intensity.

Methods: Twenty-two normal weight children (mean age [SD] 8.8 [0.9] years) performed eight different activities of different intensities. Energy expenditure was assessed using indirect caloriometry (Douglas bag technique) during these activities. Additionally, resting metabolic rate was measured at a separate occasion. Actiwatch motion sensors (Cambridge Neurotechnology Ltd Papworth, UK) were worn on the wrist of the non-dominant arm. Epoch length was set to 15 s.

Results: The equation for total energy expenditure (cal x min-1 x kg-1) was found to be 34. 44 + 0.22 x counts x 15s-1 and for activity energy expenditure 5,35 + 0,22 x counts x 15s-1. Accelerometer output explained 83% (95% CI; 0.77 to 0.89) and 86% (95% CI: 0,81 to 0,91), of the variance in total energy expenditure and activity energy expenditure, respectively. The explained variances were generally higher for prediction of activity intensity (METs) than energy expenditure (EE or AEE). Cut-off limits (95% CI) for inactivity (1.5 METs) , moderate intensity (3 METs) and vigorous intensity (6 METs) respectively was found to be 83 counts x 15s-1 (75 to 91), 251 counts x 15s-1 (226 to 274) and 584 counts x 15s-1 (531 to 637), respectively. Gender, age, resting energy expenditure and anthropometric variables increased precision only marginally.

Discussion: The present study indicates that a motion sensor, worn on the wrist of the non-dominant arm, appears to be valid for estimating energy expenditure and physical activity intensity in children aged 8 to 10 yrs. The proposed cut-off limits may be used to record time spent in physical activity of different intensities. Other measures of physical activity, such as self-reported data or direct observation, are generally less valid in children (Welk GJ et al), possibly due to the intermittent nature of their movement. Additionally, the placement on the wrist is comfortable and makes it possible to wear the monitor continuously for several days, without taking it off.

HABITUAL RESISTANCE TRAINING IN MEN ASSOCIATES WITH GREATER FOREARM VENOUS COMPLIANCE

KAWANO, H.

WASEDA UNIVERSITY

BACKGROUND and PURPOSE: Venous compliance of the extremities is a major determinant of the amount of blood that may be translocated to the central region, because small changes in peripheral blood volume can greatly impact cardiac filling pressure and subsequently cardiac output. It is reported that the venous compliance is reduced with age in sedentary and endurance-trained men, but compliance is greater preserved in endurance trained-men. Aerobic exercise as well as resistance exercise has become a popular modality of exercise performed by most populations, and has become an integral component of exercise recommendations endorsed by a number of national health organizations. It remains unclear, however, whether habitual resistance training affects venous compliance. The purpose of the present study was to compare the venous compliance in daily resistance-trained men with age-matched control men.

METHODS: Eleven resistance-trained middle-aged men (age, 37.7±1.5 yrs; height, 171.3±1.9 cm; body weight, 75.6±2.2 kg) and thirteen age-matched controls (age, 36.7 ± 1.6 yrs; height, 171.6±1.6 cm; body weight, 73.4±1.9 kg) were studied. Resistance-trained men had

been performing resistance training for over10 years. Changes in forearm volume were measured noninvasively using strain-gauge plethysmography at the maximal forearm circumference. Forearm venous compliance was measured in supine subjects by inflating a venous collecting cuff, placed around the upper arm, to 60 mmHg for 8 min and the decreasing cuff pressure at 1 mmHg/s to 0 mmHg. Forearm venous compliance was determined using the first derivative of the pressure-volume relation during cuff pressure reduction (compliance = β1 + 2•β2•cuff pressure).
RESULTS: The leg extension power and the handgrip strength in resistance-trained men were significantly higher than those in control men (2293±155 vs 1693±99 watts, 52.6±1.3 vs 44.3±1.9 kg, respectively; both p<0.05). Systolic blood pressure and mean arterial pressure were significantly higher in resistance-trained men as compared with control peers (132±4 vs 116±3 mmHg, 95±3 vs 85±2 mmHg, respectively; both p<0.05). There were no group differences in maximal oxygen consumption, resting or maximal heart rate, blood glucose, HDL-cholesterol and triglyceride. Forearm venous compliance at 20 mmHg cuff pressure was 16% greater in resistance-trained men as compared with age-matched sedentary controls (0.097±0.005 ml/dl/mmHg vs 0.083±0.004ml/dl/mmHg, p<0.05).
CONCLUSIONS: These results of the present study indicate that performing chronic resistance training may increase venous compliance in middle-aged men, suggesting that greater venous compliance with habitual resistance exercise may have important implications regarding arterial blood pressure regulation during orthostatic stress or during exercise in healthy adult men.

BONE MINERAL DENSITY AND IGF-1 IN 13-15 YEAR OLD FEMALE ATHLETES

GRUODYTE, R., JÜRIMÄE, J., SAAR, M., JÜRIMÄE, T.
UNIVERSITY OF TARTU; LITHUANIAN ACADEMY OF PHYSICAL EDUCATION, LITHUANIA

Introduction: It is well known that insulin-like growth factor-1 (IGF-1) is an effective osteoporotic growth factor, which increase dramatically during puberty, augmented by the increasing levels of sex steroids, and positively affects bone turnover by stimulating osteoblasts proliferation and differentiation (Davies et al., 2005). Bone mineralization increases with age, height, and body mass increase throughout childhood, with a significant gain during pubertal development, resulting in an increase of BMD of about 40% during this period (Gordon, 1991). The aim of this cross-sectional study was to evaluate the relationships between BMD and IGF-1 in adolescent female athletes.
Methods
The participants were eighty 13-15 year-old girls comprising three groups: gymnasts (n=23), sprinters (n=24) and controls (n=33). Body height and body mass were measured, and body mass index (BMI) was calculated (kg/m2). BMD at lumbar spine (L2-L4) and femoral neck (FN) were measured by DXA. Morning fasting blood samples were collected for analysis of IGF-1 and IGFBP-3, and IGF-1/IGFBP-3 molar ratio was calculated. For those girls who had menarche, the fasting blood samples were drawn on early follicular phase of the menstrual cycle.
Results: Gymnasts BMD FN was significantly higher than sprinters and controls (1.13 ± 0.15 vs. 1.05 ± 0.09 and 1.01 ± 0.11 g/cm2, respectively). The levels of IGFBP-3 were significantly greater in gymnasts than in sprinters (6.0 ± 0.7 vs. 5.5 ± 0.7 mg/L, respectively). There were significant correlations of IGF-1 and IGF-1/IGFBP-3 molar ratio with BMD FN and L2-L4 (r = 0.39-0.59) in gymnast and control groups, but not in sprinters. After adjusting for age, body height and body mass, the significant correlations between IGF-1 and BMD variables (r = 0.49-0.52) were revealed in gymnast group only. Stepwise multiple regression analysis indicated that BMD FN and L2-L4 were influenced by IGF-1 up to 31.0-34.6 % (R2x100) in gymnasts, and by IGF-1/IGFBP-3 – up to 19-32 % (R2x100) in controls.
Discussion: In our study, no significant differences between the groups were found in respect to IGF-1 levels and IGF-1/IGFBP-3 ratio, but BMD FN was significantly greater in gymnasts. Previously, IGF-1/IGFBP-3 was indicated as the most robust predictor of femoral neck BMD in young adult women with different physical activity patterns (Snow et al., 2000). This corresponds well with our research findings, although the significant relationships of BMD FN and L2-L4 with IGF-1 levels and IGF-1/IGFBP-3 ratio were found in pubertal gymnast and controls, but not in sprinters. We conclude that IGF-1 is strongly correlated with BMD FN and L2-L4 in adolescent gymnasts, but not sprinters.

THE CELLULARITY OF ADIPOCYTE AND SECRETION OF ADIPOCYTOKINES DURING AND AFTER VOLUNTARY WHEEL RUNNING EXERCISE IN HYPERPHAGIC AND OBESE OLETF RATS

KIMURA, M., SHINOZAKI, T., TAKIUE, Y., HOSOYAMADA, M., SHIBASAKI, T.
KEIO UNIV.

The purpose of this study was to investigate the optimal weight reduction program for the exercise therapy. We tested about the relationships between cellularity of adipocytes and secretion of adipocytokines at the end and 2-day after of voluntary wheel running exercise.
Otsuka Long-Evans Tokushima Fatty (OLETF) rats, an animal model of hyperphagia and obesity, were used in this study (19-week-old at the end of experiment). The rats were randomly assigned to either the 4-week voluntary wheel running exercise (15 to 19-week-old) or control group (Cont). The half numbers of exercising rats were killed at the end of exercise period (Ex-end), and the others were assigned to the 2-day recovery period at which these rats were prohibited from accessing to running wheel (Ex-recov). Throughout the experimental period, all rats were provided with water and standard chow food ad libitum. For the quantification of number and size of adipocyte, adipose tissue were fixed with 10% formalin phosphate buffer, and the sectional cell diameter of adipocyte were analyzed in the hematoxylin and eosin stained preparations. Adipocytokine levels in blood were measured using ELISA kit.
Compared to Cont group, Ex-end group exhibited the remarkable reduction in body weight, abdominal fat pad weight, blood leptin concentration, and size of adipocyte in abdominal fat pads. Compared to Ex-end group, Ex-recov group provided a marked increase in body weight, although there were no changes in weight and size of adipocyte in abdominal fat pads. Unexpectedly, blood leptin concentrations in Ex-recov group were higher than in Ex-end group.
These results suggested that the regulatory mechanism in expression and/or secretion of leptin from adipocyte is different between during and after exercise therapy.

IS SKELETAL MUSCLE LEPTIN SENSITIVITY REDUCED BY BED REST?

FUENTES, T., GUERRA, B., GUADALUPE-GRAU, A., SANTANA, A., MORALES-ALAMO, D., PILEGAARD, H., CALBET, J.A.L.

ULPGC (LAS PALMAS GC, SPAIN). GENETIC UNIT CHIMI (LAS PALMAS GC, SPAIN). RESEARCH UNIT HGCDRN (LAS PALMAS GC, SPAIN). DEPARTMENT OF BIOLOGY CU (COPENHAGEN, DENMARK).

Human obesity is mainly caused by a sedentary life style and is characterised by a high concentration of leptin in plasma associated with leptin and insulin resistance in peripheral tissues, such as skeletal muscle. Skeletal muscle expresses long and short protein isoforms of the leptin receptor. A mechanism that could explain skeletal muscle leptin resistance in obesity is a down-regulation of leptin receptors (OB-Rs) and/or up-regulation of suppressor of cytokine signaling 3 (SOCS3) and protein-tyrosine phosphatase 1B (PTP1B) which are negative regulators of insulin and leptin signaling. Both obesity and bed rest may induce inflammation and according to rodent experiments PTP1B protein expression may be increased by inflammation in skeletal muscle. Therefore, the aim of this study was to test the hypothesis that bed rest causes down- and upregulation of OB-R and SOCS3/PTP1B protein expression, respectively, in human skeletal muscle.

Methods. Deltoid and Vastus Lateralis muscle biopsies were obtained from 12 healthy men before and after one week bed rest performed in eucaloric conditions (mean ± SD, age: 26.2 ± 5.3 years; height: 181.7 ± 6.1 cm; body mass: 75.5 ± 11.2 kg; BMI: 22.8 ± 2.7 kg/m2 and VO2max: 3.9 ± 0.8 L/min). Total protein extracts were prepared from muscle biopsies and OB-R, SOCS3 and PTP1B protein expression was analyzed by Western blot. Serum leptin and soluble isoform of the leptin receptor (sOB-R) concentrations were determined by ELISA before and after bed rest.

Results. Serum leptin concentration was increased by 26% after bed rest compared with before bed rest ($P<0.05$). However, serum s-OBR concentration was unaffected by bed rest ($P=0.6$). Alpha tubulin protein expression, used as a loading control in our immunoblotting assays, was not affected by bed rest in either the deltoid or Vastus Lateralis muscle biopsies (both $P>0.05$ compared with before bed rest). OB-R (short and long isoforms) and SOCS3 protein expression normalized to alpha-tubulin was unchanged after bed rest compared with before bed rest in deltoid and Vastus Lateralis muscles (all $P>0.05$). PTP1B protein expression normalized by alpha-tubulin was unaffected by bed rest in deltoid muscle biopsies ($P>0.05$). However, PTP1B protein content in Vastus Lateralis muscle was 90% higher after bed rest than before bed rest ($P<0.01$).

Conclusions. PTP1B protein expression is markedly increased in human Vastus Lateralis but not in the deltoid muscles after one week of bed rest. Since PTP1B is able to dephosphorylate the insulin receptor and also the Janus Kinase 2 (JAK2) (first step in leptin signalling), it may induce both insulin and leptin resistance. Moreover, our results indicate that one-week bed rest elicits leptin resistance as reflected by the increased basal leptin serum concentration and its free fraction, despite no significant changes in body fat mass.

IS EXERCISE A LEPTIN SIGNALLING MIMETIC IN HUMAN SKELETAL MUSCLE?

PONCE-GONZÁLEZ, J.G., GUERRA, B., GUADALUPE-GRAU, A., FUENTES, T., OLMEDILLAS, H., SANTANA, A., DORADO, C., CALBET, J.A.L.

UNIVERSITY OF LAS PALMAS DE GRAN CANARIA. CHILDHOOD HOSPITAL-INSULAR-MATERNO INFANTIL DE LAS PALMAS. HOSPITAL DE GRAN CANARIA DR. NEGRÍN

Leptin plays a crucial role in the regulation of appetite, body fat mass and basal metabolic rate. Upon binding to the long form of its receptor (OB-Rb), leptin stimulates janus kinase 2 (JAK2) and signal transducer and activator of transcription 3 (STAT3) phosphorylation. OB-Rb mediated phosphorylation of STAT3 is required for leptin regulation of energy balance and body weight. In lean, but not in obese human skeletal muscle, leptin is able to stimulate fatty acid oxidation, suggesting triglyceride accumulation and lipotoxicity in obesity could be caused by changes in the leptin signaling cascade. Leptin may down-regulate leptin signaling in the target tissues by inducing the protein suppressor of cytokine signaling 3 (SOCS3), which blunts JAK2/STAT3-dependent leptin signaling and causes leptin resistance in the skeletal muscle. Protein-tyrosine phosphatase 1B (PTP1B) is a negative modulator of leptin and insulin signaling because is able to dephosphorylate JAK2 and the insulin receptor and may explain leptin and insulin resistance in peripheral tissues. Exercise partially prevents muscle leptin resistance in rodents. Therefore, the aim of this study was to study if sprint exercise could be a leptin signalling mimetic in human skeletal muscle.

Methods. Tyr1007/1008-JAK2 and Tyr705-STAT3 phosphorylation level and SOCS3/PTP1B protein expression were determined by western blot in fifteen young healthy men in response to a 30 s sprint exercise (Wingate test). Subjects were randomly distributed into two groups. One group exercised under fasting conditions (n=7, C), and the other ingested 75g of glucose (G) one hour before exercising (n=8).

Results. Tyr1007/1008-JAK2 phosphorylation was unaffected in the control Wingate test (all $P>0.05$ versus rest). In contrast, compared to pre-exercise levels, Tyr1007/1008-JAK2 phosphorylation was increased 120 min after the Wingate test performed following glucose ingestion ($P<0.05$). Compared to pre-exercise conditions, Tyr705-STAT3 phosphorylation was increased 30 min after the sprint exercise ($P<0.05$). Glucose ingestion blunted the increase in Tyr705-STAT3 phosphorylation detected 30 min after the Wingate test. In the glucose group, 2 hours ($P<0.05$) and 4h ($P<0.05$) after the Wingate test Tyr705-STAT3 phosphorylation was increased compared to pre-exercise levels. Compared to pre-exercise conditions, SOCS3 protein expression was increased 120 min after the sprint exercise ($P<0.05$ versus resting). Glucose ingestion blunted SOCS3 protein expression increase 120 min after the Wingate test. The level of PTP1B protein expression was not affected by either glucose ingestion or exercise (all $P>0.05$).

Conclusions. STAT3 phosphorylation level and SOCS3 protein expression is markedly increased 30 and 120 min respectively, after sprint exercise. These responses were blunted by oral glucose ingestion. Our results suggest that sprint exercise performed in fasting conditions is a leptin signalling mimetic in human skeletal muscle.

IS AEROBIC ENDURANCE A DETERMINANT OF THE AMPLITUDE OF THE SLOW COMPONENT OF THE V ̇O_2 KINETICS DURING AN EXERCISE OF SEVERE INTENSITY?

BOSQUET, L., LAROTUROU, M., LHEUREUX, O., CARTER, H.

UNIVERSITY OF POITIERS

Introduction: It is generally considered that performance in long duration events is mainly determined by maximal oxygen consumption (VO2 max), the energy cost of locomotion and the fractional utilization of VO2 max (also called aerobic endurance). It has been proposed that the amplitude of the slow component of the VO2 kinetics during severe intensity exercise should be added to this model. Since this variable shares many underlying mechanisms with aerobic endurance, we wanted to determine whether these two physiological parameters were independent one to each other.

Methods: Thirty moderately-trained male endurance athletes gave their written informed consent to participate in this study. They completed a maximal continuous graded exercise test (session 1), followed by two randomly ordered constant power tests (sessions 2 and 3), and a constant duration test (session 4). All tests were performed on a bicycle ergometer, Constant power tests were performed at an intensity corresponding to 90 and 100% of peak power output (PPO) measured during session 1. The slope of the relationship between intensity of exercise and the natural logarithm of time to exhaustion was considered as the index of aerobic endurance (IE, unitless), and used afterwards as the criterion measure for aerobic endurance. The slope of the relationship between work and time was considered as the critical power (CP, in W), and used afterwards for intensity determination during session 4. Constant duration test consisted in two bouts of 6 minutes of exercise at an intensity corresponding to 30% of the difference between CP and PPO. Sixty minutes of passive recovery were given between the two bouts of exercise. Oxygen uptake was determined continuously on a breath-by-breath basis during session 4. The signals from both tests were resampled to second by second and ensemble-averaged to produce an average response. A classical bi-exponential model was used to fit this new signal and estimate the amplitude of the slow component.

Results: Once the study completed, participants were ranked according to their IE. The median-third was excluded. The higher third formed the high aerobic endurance group (HEG) and the lower third formed the low aerobic endurance group (LEG). There was no overlap in IE between groups. Mean VO2 peak and IE for HEG and LEG were 4122 ± 511 vs 3911 ± 825 ml.min-1 (NS) and -21.7 ± 3.4 vs -13.9 ± 0.7 ($p < 0.001$), respectively. The amplitude of the VO2 slow component was not different between groups (626 ± 96 vs 536 ± 168 ml, corresponding to 26 ± 3 vs 24 ± 7 % of end exercise VO2, respectively; NS) and was not associated with IE ($r = 0.14$, NS).

Conclusion: Contrarily to our hypothesis, the amplitude of the VO2 slow component was not associated with aerobic endurance. It can therefore be considered as a possible independent predictor of performance in long duration events. Future studies should assess its relative weight when compared with the classical determinants.

A NEW MODEL AND MEANS OF ANALYSIS FOR THE HEART RATE KINETICS IN RESPONSE TO EXERICSE

STIRLING, J., ZAKYNTHINAKI, M.S.

UNIVERSIDAD POLITECNICA DE MADRID

Introduction: Mathematical models in the form of a nonlinear dynamical system have recently been developed both for heart rate (Stirling et al, 2008a) and oxygen uptake kinetics (Stirling et al, 2008b, 2005). The point of maximum curvature has been proposed by Stirling and Zakynthinaki, (2008) as a marker for physiological time series. This marker defines the point after which the heart rate no longer continues to rapidly rise and instead follows either a steady state or slow rise (i.e. the slow component). The aim of this study is to apply these methods of analysis and models to examine the way the point of maximum curvature changes with improved fitness resulting from training.

Methods: Beat to beat heart rate data were obtained from an athlete who performed a series of bouts of exercise at different constant intensities. The optimal fit of the heart rate model to the basic response pattern (Zakynthinaki et al, 2007) of the raw un averaged data was obtained used a stochastic optimization algorithm (Zakynthinaki and Stirling, 2007; 2008). The point of maximum curvature was then calculated using the method described in Stirling and Zakynthinaki (2008). The same point is calculated for the same exercise intensity following a period of training which has resulted in speeded kinetics.

Results: It was observed that by calculating the point of maximum curvature, the time and the value of the heart rate at which the heart rate time series changes from a rapidly rising function to either a steady state or slow component was easily detected. The point of maximum curvature was also found to change with speeded kinetics following a period of training.

Discussion: A method based on obtaining the point of maximum curvature was used for determining the time and heart rate (or oxygen uptake) after which a plateau or a slow component in the heart rate (or oxygen uptake) kinetics is achieved. This method was shown to be of much use for understanding the heart rate kinetics in response to constant intensity short duration exercise. We concluded that the point of maximum curvature is a useful tool for understanding speeded heart rate kinetics following training. This method also has many applications in similar problems in oxygen uptake kinetics.

TECHNICAL MODIFICATION OF THE METAMAX II METABOLIC ANALYZER FOR MEASUREMENTS ON FIREFIGHTERS IN THE HEAT

SYNNES, O., MEDBØ, J.I., VON HEIMBURG, E.
NATIONAL INSTITUTE OF OCCUPATIONAL HEALTH

Background

Fire-fighting is physically very demanding. Testing of firefighters' physical ability is needed, but there is no close agreement between performance on standard laboratory tests and results of simulated rescue operations [1]. This suggests that tests should be carried out on fire-fighting-related activities, which may include tasks in the heat. The Metamax II (Mmx) is a portable metabolic analyzer that allows field testing [2]. This instrument like all electronic instruments does not tolerate heat. Moreover, the Mmx' software requires that both inspired and expired air is passed thru its triple V flow transducer to work properly. When firefighters work at the scene of fire, they are dressed up for smoke diving, inspiring from bottles with pressurised air led to the face mask thru a solid tube. Expired air is released to the surroundings. Consequently, during smoke diving only expired air is available for analysis by the Mmx. Therefore, to measure the oxygen uptake of firefighters during smoke diving by the Mmx, we had to modify the instrument. We here describe our approach.

Principle of operation

The Triple V flow transducer is a turbine-type flow-meter a light-weight fan rotates in proportion to the flow. Two sets of diodes and photocells (flow 1 and flow 2) record each rotation, and the sequence 1–2 or 2–1 distinguishes between inspiration and expiration. Only data for expirations are used for further calculations, but the software requires an inspiration signal between two expirations to work properly.

Methods: An extension to the cable connecting the Triple V to the main unit was cut. The individual wires of the cut ends were mounted on a small circuit board with a Pic 16F 628/20 microprocessor, programmed to pass all signals thru during expiration. After a complete expiration the microprocessor produced an artificial inspiration signal. Noise was removed. The signal in each wire during use was read on an oscilloscope.

Connections to fit the Triple V to the outlet of the Interspiro face mask were made, thus allowing expired air to pass from the mask thru the Triple V. The Mmx II was placed in a dedicated heat-protected box mounted out the subject's back, and tubes as well as the Triple V were heat protected by isolating materials.

Results: With no inspiration signal the software did not work properly, reporting a lung ventilation at least 30% too low. The microprocessor reproduced the square-wave signals even during maximal expirations. During exercise lasting up to 8 min in a heat chamber (t > 120 °C) the temperature in the heat protecting box stayed below 30 °C.

Conclusions

By proper modifications the Mmx II may be used to measure the oxygen uptake of firefighters dressed up for smoke diving even in hot and polluted environments.

EFFECTS OF LOAD CARRIAGE AND POLES USE ON WALKING VELOCITY AT FIELD TRACKS

FERNANDES, R., BRITO, J., REIS, V., CONCEIÇÃO, A., LOURO, H.
ESCOLA SUPERIOR DE DESPORTO DE RIO MAIOR

INTRODUCTION: The use of the walking poles has increased, however de literature still does not a consensus about their benefits. It as also been reported that the load carriage with poles use, spite of reducing the mechanical load of the lower limb may cause higher fatigue. The purpose of this study was to determine the effects of poles and load carriage on the walking velocity and on rate of perceived exertion (RPE). The velocity was examined for four walking condition: non-poles and non-load (W), with poles and non-load (WP), non-poles and with load (WL), with poles and with load (WLP).

METHODS

Twenty six healthy masculine volunteers walked at a self-selected pace during a pedestrian field track with 821 m long on level terrain (mean±SD, age 23,30 ± 2,69 years; body weight 76,96 ± 12,19 Kg; height 176,25 ± 5,70 cm; body fat percentage 14,69 ± 5,89%). The subjects completed each trail in a randomized order after return to the metabolic rest values between trails. The rest heart rate (HR) and oxygen consumption (VO2) were recorded by a portable telemetric system. Rating of perceived exertion (RPE) was measured at the end of each trial by the modified Borg scale (1-10)[1]. The weight carriage was 25% of the subject's body mass, in a backpack with internal frame, sternum strap, hip belt and load lifters adjusted for each subject as well the telemetric poles.

RESULTS: Significantly differences were not found in RPE for comparisons M vs MP and ML vs MLP. Walking speed shows a significantly decrease (= 0,05, IC 95% 0,01 to 0,1, P 0,05) between M vs MP.

CONCLUSIONS

The results indicate that the use of poles doesn't increase the perceptive demands (RPE). The use of poles at load carriage didn't alter RPE and the walking speed. These results indicate that the use of poles may point as a strategy to reduce perceptions of physical exertion associated to the load carriage.

HEART RATE, VO2, BLOOD LACTATE, RECTAL TEMPERATURE AND VERTICAL JUMP MEASURED DURING CONTINUOUS AND INTERMITTENT <110% IAT> PROTOCOLS

AGUADO-JIMENEZ, R., IZQUIERDO, M., NAVARRO, I., RUESTA, M., GOROSTIAGA, E.M.

1. FACULTAD CIENCIAS DEL DEPORTE. UNIVERSIDAD DE CASTILLA-LA MANCHA, 2. CENTRO DE ESTUDIOS, INVESTIGACIÓN Y MEDICINA DEL DEPORTE. INSTITUTO NAVARRO DE DEPORTE Y JUVENTUD

INTRODUCTION: Objectives of the study were to analyze the response on VO2 (Vacumed mini-cpx), heart rate, blood lactate concentration, rectal temperature and maximal vertical jump during two intensities of treadmill protocol.

METHODS: Subject

Eleven male were recruited to take part in the study. Selection criteria included male; age 25-44 yr; high aerobic fitness, defined 62.6 (4.2) mL•Kg-1•min.

Protocol

Treadmill speeds were set at 100% (CON) of the individual velocity of the anaerobic, and of the same velocity (INT110), always preceded by 2.69 m•s-1 for 10 min of warm-up at level grade. Speed was kept constant for all remaining stages. During intermittent trials, every 3 min thereafter treadmill was stopped during 2 minutes, while in continuous trial this resting period was every 13 minutes. In both protocols this sequence was until the subject signalled that he had reached exhaustion.

Measures

Anaerobic threshold was determined during a maximal incremental test independently by two experienced individuals who compared their results and reached a consensus. Graphs of VE over time, Ve over •VO2, and/or Ve/•VO2 over •VO2 were used for this determination. This method of determining VT has been shown to be accurate and reliable (3)

The tests were performed at least 2 day apart but no more than 7 days apart

Statistical Analysis

Mean values and standard of deviation (SD) were calculated for all parameters. Comparisons during the protocols were done using analysis of variance (ANOVA)

Statistical significance was accepted at P < 0•05.

RESULTS: At the end of exercise trial (3, 13, 28, 43 minutes, and exhaustion time) VO2 were not different in INT110 (50.0±4.4; 52.1±5.1; 51.4±4.9; 52.2±5.4; 53.2±5.4 mL•kg-1) and CON (46.5±5.8; 51.5±5.1; 51.3±5.1; 53.0±4.4; 55.2±4.6 mL•kg-1). Blood lactate was not different in INT110 (1.0±0.3; 4.1±1; 4.3±1.2; 4.7±1.5; 6.0±1.8 mM) and CON (1.1±0.4; 4.0±0.9; 4.3±0.9; 4.7±1.1; 6.2±1.5 mM). Heart rate was not different in INT110 (164±11; 173±10; 178±7; 181±9; 186±5 bpm) and CON (158±9; 171±9; 177±8; 182±6; 188±6 bpm). Rectal temperature increased at a greater rate during the exercise in CON than in INT110, getting values of 39.8±0.1 vs. 39.3±0.1 (P<0.05) Basal stage was not different between both protocols. Time flight measured in the CMJ was no different in CON than in INT110, finding that before exhaustion, subjects had greater time flight in compare to basal values, only in INT110 (550.9±43vs 537.4±39ms p<0.05).

DISCUSSION/CONCLUSION

Continuous exercise at anaerobic threshold intensity, produce similar effects that intermittent exercise 110% of anaerobic threshold intensity, in VO2, heart rate, and lactate accumulation, but the core temperature is lower in intermittent exercise what allows to get fatigue later than in continuous exercise. These results obtained in intermittent exercise are showed in the maintenance of the legs power capacity during the vertical jump.

PHYSIOLOGICAL COMPARISON OF TWO TREADMILL EXERCISE PROTOCOLS FOR THE DETERMINATION OF LACTATE THRESHOLD AND VO2MAX

JACKSON, A., LAING, S., LAW, R., EARING, C., CARDINALE, M.

1. OLYMPIC MEDICAL INSTITUTE, 2. BANGOR UNIVERSITY

Introduction: Laboratory treadmill running tests are commonly used to assess the effects of training programmes and to prescribe training intensities for athletes. It is well established that some variability in the results exists as a consequence of varying the testing protocols (Froelicher et al. 1974; Pollock et al. 1976).

Aim: The purpose of this study was to determine the differences in two commonly used treadmill protocols for the determination of lactate threshold (LT) and VO2max.

Method: Eight healthy, recreationally active volunteers (mean +/- SD: age; 24 +/- 5 years, height; 177.8 +/- 4.8cm, mass; 73.9 +/- 10.8kg) participated in the study. All subjects completed two maximal graded treadmill (MGT) tests to volitional exhaustion in a randomised order. Expired air samples and heart rate were measured continuously throughout and earlobe blood samples were taken for the determination of blood lactate. On completion of each trial VO2max was determined by averaging the highest observed consecutive values over one minute. LT was identified as described by Weltman et al. (1990). Protocol # 1 comprised a 5 minute warm up at 10km.h-1 after which, the gradient was fixed at 1% and starting speed was 11km.h-1. Stages were 4 minutes in duration, at the end of which speed was increased by 0.6 km.h-1. Once blood lactate reached 4mmol.L-1, speed remained fixed and the gradient was increased by 1% every minute until volitional exhaustion was reached. Protocol # 2 comprised a 5 minute warm up at 10km.h-1. Gradient was fixed at 7.5%. The starting speed was 8km.h-1 and increased by 1km.h-1 every 3 minutes until volitional exhaustion was reached.

Results: All statistical analysis was conducted using SPSS version 12.0 for windows. Paired samples t-tests were used to determine any differences between the two protocols. Alpha was set at P <0.05. No significant differences were found between any of the variables.

Conclusion: Both tests are equally valid in a group of trained individuals.

EFFECTS OF PHARMACOLOGICAL BLOCKADE ON HEART RATE DYNAMICS IN PARTICIPANTS WITH SPINAL CORD INJURY

MILLAR, P., COTIE, L., ST. AMAND, T., MCCARTNEY, N., DITOR, D.
MCMASTER UNIVERSITY

Cardiovascular and autonomic dysfunction are common impairments in patients with spinal cord injury (SCI) (Krassioukov and Claydon, 2006). Non-linear heart rate (HR) variability techniques may help to detect subtle changes in HR behaviour (Mäkikallio et al., 2002), though the physiological basis of these measures in patients with SCI remains unknown. The present study examined the effects of pharmacological blockade on non-linear measures of HR dynamics in participants with incomplete tetraplegia. Measurements were taken during rest, sympathetic blockade with intravenous metoprolol (3 x 5 mg, each separated by 5 min), and vagal blockade with intravenous atropine (0.02 mg/kg), in the supine and cardiovascular stress positions. The cardiovascular stress position included simultaneous 40° tilt plus cold pressor (10°C) and isometric jaw contraction. Under these conditions, HR dynamics were assessed using sample entropy, detrended fluctuation analysis ($\alpha 1$ and $\alpha 2$), and correlation dimension techniques. Five male participants (41.7 ± 6.0 yrs; lesion level: C4-C7; ASIA scale: B-D, 13.4 ± 3.0 yrs post injury [mean ± SEM]) completed the study protocol. HR exhibited a significant effect for condition ($p<0.001$) and position ($p<0.05$). Non-linear measures were unchanged with metoprolol in both positions, compared to baseline. Atropine reduced sample entropy (1.48 ± 0.07 to 0.44 ± 0.09, $p<0.01$) and correlation dimension (2.90 ± 0.70 to 0.05 ± 0.02, $p<0.05$) while increasing $\alpha 2$ (0.77 ± 0.11 to 1.34 ± 0.12, $p<0.05$) in the supine position. Atropine also reduced $\alpha 1$ (1.29 ± 0.09 to 0.96 ± 0.11, $p<0.01$) and correlation dimension (1.13 ± 0.30 to 0.11 ± 0.11, $p<0.05$) during the cardiovascular stress position. A significant interaction effect was detected for sample entropy as values during baseline (1.48 ± 0.07 vs. 1.00 ± 0.07, $p<0.001$) and following atropine (0.44 ± 0.09 vs. 0.85 ± 0.07, $p<0.05$) differed between the supine and cardiovascular stress positions. Correlation analysis revealed significant associations between HR and non-linear measures ($p<0.01$). Thus, in comparison to blockade of the β1-adrenoreceptor system, vagal modulation is the main determinant of non-linear HR measures in male participants with incomplete tetraplegia. These measures may be useful in assessing neurocardiac function in clinical populations and requires further exploration.

ARTERIAL STIFFNESS OF JAPANESE JUNIOR HIGH SCHOOL STUDENTS IN 12-15YEARS OLD

MATSUMOTO, N., MIYACHI, M., TORIOKA, J., HIGASHI, Y., YOSHIOKA, A., KOMIYAMA, M., ONODERA, S.
GRADUATE SCHOOL OF KAWASAKI UNIVERSITY OF MEDICAL WELFARE

Purpose;
The arterial stiffness is an independent risk factor of cardiovascular diseases. The arterial stiffness was measured by the pulse wave velocity between brachial and ankle arteries (baPWV). In adults, it is known that the arterial stiffness increases with age. However, there are few reports to show relationship of the secondary sexual characteristic period and the arterial stiffness. It is considered that the secondary sex characteristic begins around 11years old in men, 9years old in women as for Japanese. Therefore, we estimated that junior high school students(age of 12-15) were in the secondary sex characteristic period. We examined the relationship of the arterial stiffness and the secondary sex characteristic.
Methods;
Sixty-eight Japanese junior high school students participated in this study (1st grade: men;n=12, women;n=11. 2nd grade: men;n=11, women;n=12. 3rd grade: men;n=15, women;n=7). All subjects were engaged in some kind of sport activities. We compared their arterial stiffness with their grade in school advanced. In addition, we examined the relationships between the degree of obesity and the arterial stiffness. We used Hibi-type (overweight child determination method in Japan) for a determination of the degree of obesity. We divided subjects into three groups depending upon the degree of obesity; overweight-group of over 20%, normal-group of 19~-19%, underweight-group of under –20%. We excluded underweight-group of women, because it was alone.
Results;
The baPWV of men increased with their grade in school advanced (1st graders 804±73, 2nd graders 871±144, 3rd graders 942±183cm/s). The 3rd graders were significantly higher than the 1st graders. On the other hand, the baPWV of women significantly decreased with their grade in school advanced (1st graders 973±102, 2nd graders 830±87, 3rd graders 763±104cm/s). The 1st graders were significantly higher than the other grades. When we divided men into overweight-group(n=11, 1011±241cm/s), normal-group(n=16, 843±125cm/s), underweight-group(n=15, 854±94cm/s), the baPWV of overweight-group was significantly higher than the other groups. However, no significant difference was seen in the baPWV in women between overweight-group(n=9, 891±121cm/s) and normal-group(n=20 863±130cm/s).
Discussion;
In the present data, junior high school students who predicted in the middle of the secondary sex character period, the arterial stiffness of men increased with age. However, women decreased. It is evident that the arterial compliance increases by the estrogen secretion in adult women. We are considered that a low arterial stiffness of women is related to the increase in the production of estrogen. Meanwhile, the arterial stiffness in overweight-men was increased even though they engaged in sports activities. However, there was no significant difference in the overweight-women. These results suggest that it is a different blood vessel dynamics in men and women of the secondary sex character period.

THE IMPACT OF A FEMALE INTERNATIONAL FIELD HOCKEY TOURNAMENT ON PERFORMANCE AND MARKERS OF IMMUNE STATUS AND MUSCLE DAMAGE.

MACUTKIEWICZ, D., SUNDERLAND, C.

NOTTINGHAM TRENT UNIVERSITY

Background: International field hockey tournaments requires teams to play a series of matches on consecutive days with no more than 1-2 days recovery before the next match. Little is known about the performance and physiological impact of such a schedule on elite female players. In male international field hockey players alterations in motion characteristics and the intermittent nature of the activity are altered with repeated match exposure (Sunderland et al., 2008). The aim of the present study was to assess the impact of a tournament schedule on performance, markers of immune status and muscle damage of elite female hockey players.

Method: Ten female international field hockey players gave informed consent to participate in the study. The mean (SD) age and mass of the players were 25.2 (4.0) years and 64.4 (6.4) kg respectively. Data were collected during a 5 day tournament (non ranking) period comprising: day 1-2, and 4-5 match days and day 3 recovery day. Fasted capillary blood samples were taken on all days. Plasma samples were analysed for immunoglobulin A (IgA), Creatine Kinase (CK), C-reactive protein (CRP) and Urea. Unstimulated saliva samples were taken for all days and analysed for testosterone, cortisol and testosterone/cortisol ratio (T/C ratio). A global positioning system was used to assess distance covered at particular speeds ('standing' 0-0.7; 'walking' 0.7-6.1; 'jogging' 6.1-11.2; 'running' 11.2-15.1; 'fast running' 15.1-19.1; 'sprinting' >19.1 km/h), intensities ('low' 0-6.1; 'moderate' 6.1-15.1; 'high' >15.1 km/h) and heart rate. Data was analysed using 1- and 2-way ANOVA with repeated measures. Statistical Significance was set at $P<0.05$.

Results: No differences were observed in the mean distance covered between games 1-4. As the tournament progressed no significant differences were observed in the distances covered in motion type or intensity. IgA was significantly lower on day 3 (1.46 (0.6) g/l, $P=0.018$) when compared to day 4, which corresponded to two consecutive matches (Day 1 and2) and a recovery day on day 3. CK increased from 116.0 (28.8) U/l at rest to 165.9 (42.8) U/l ($P=0.026$) after the second game, reduced below initial baseline following a recovery day and subsequently increased after the following game (181.7 (77.1) U/l; $P<0.001$).

Conclusions: The repeated match play experienced in the present tournament did not result in any residual or accumulated fatigue. It is possible that a more demanding competitive schedule such as that experienced during the Olympic Games will have an effect of the activity patterns of players during later matches.

THE EFFECT OF DELAYED ONSET OF MUSCLE SORENESS ON HABITUAL TRAPEZIUS ACTIVITY

MORK, P.J., WAKEFIELD, E., HOLTERMANN, A.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM, NORWAY

Introduction: The frequently cited pain adaption model (Lund et al 1991) predicts that muscle pain, acute or chronic, will cause inhibition of muscle activity to protect the muscle from further damage. The model is supported by laboratory studies but there is a lack of studies investigating the effect of muscle pain on habitual muscle activity during daily activities. The aim of the study was to investigate whether acute upper trapezius pain, caused by delayed onset of muscle soreness (DOMS), influences habitual trapezius activity.

Methods: Eleven right-handed female subjects (mean age 22 yrs, range 20-24 yrs) were recruited from a convenience sample of university students. Long-term (5 hrs) surface electromyographic (sEMG) activity was recorded (Myomonitor III, Delsys, US) bilaterally from the clavicular, descending, transverse, and ascending parts of trapezius on two consecutive weekdays. Inclinometers were used to record body posture (sitting, standing, walking) and bilateral upper arm movement synchronously with sEMG. Subject where instructed to maintain normal daily activities during recordings but to avoid vigorous physical activity. Immediately after the first field recording, muscle pain was induced to the left upper trapezius by eccentric shoulder depression exercise. Assessment of pressure pain threshold (PPT) at the start of the field recordings and hourly pain scores on visual analogue scale (VAS) during the field recordings was used to quantify trapezius pain.

Results: PPT decreased for the left medial, center, and lateral part of the upper trapezius ($P<0.004$ for all comparisons) from day 1 to day 2. PPT remained unchanged in the lower left and right trapezius. VAS scores increased from day 1 to day 2 for the left upper trapezius ($P<0.004$). The root-mean-square median sEMG level increased during seated posture for the left descending trapezius ($P<0.05$). Trapezius activity remained unchanged in all other parts of the left trapezius and all parts of the right trapezius. Arm elevation, arm movement, and time with different body postures remained unchanged from first to second field recording.

Discussion: Trapezius pain (i.e., DOMS) was demonstrated by the reduced PPT at the three sites associated to the exercised upper part of the left trapezius and by the raised hourly VAS scores during the second long-term recording. An increased level of sEMG activity in the pain-afflicted descending part of the left trapezius was observed in periods with seated posture, i.e., situations with very low muscle activity or nominal muscle rest. These findings indicate that nociceptive input induces increased trapezius muscle tonus during periods with low biomechanical loading. Thus, the present study opposes the prediction of the pain adaption model.

THE EFFECTS OF EXERCISE-INDUCED MUSCLE DAMAGE ON CYCLING ENDURANCE PERFORMANCE

BURT, D., TWIST, C.

UNIVERSITY OF CHESTER

The effects of exercise-induced muscle damage on cycling endurance performance

Burt, D.G. & Twist, C.

University of Chester

Introduction: The benefits of including resistance-based training for optimising endurance performance (Paavolainen et al., 1999) would suggest that endurance athletes engage more frequently in training that might cause symptoms of exercise-induced muscle damage (EIMD). Whilst, EIMD has been reported to impair muscle strength and power (Twist & Eston, 2007), the effects on endurance performance during ecologically valid settings have yet to be elucidated.

Method

Following ethical approval, 17 participants were randomly assigned to either a treatment (n = 8) or control group (n = 9). Participants initially performed an incremental ramp protocol on a cycle ergometer to establish the workload corresponding to ventilatory threshold (VT). After a minimum of 24 h, participants performed a 5-minute fixed-intensity cycling at VT, followed by a 15-minute cycling time-trial. Physiological, metabolic, and perceptual responses were measured during both fixed workload and time-trials. Perceived levels of muscle soreness and peak isokinetic knee extensor torque at 60 deg.s-1 were also recorded. Following 30 minutes rest from baseline measures, participants in the treatment group performed 10 x 10 plyometric jumps to induce symptoms of EIMD. After a further 48 h, measurements of perceived muscle soreness, peak isokinetic strength, and endurance performance during fixed-intensity and time-trial cycling were repeated.

Results: Significant interactions of time and group indicated increased muscle soreness and reduced knee extensor strength ($P < 0.05$) for the treatment group following EIMD. No significant interactions of time and group on heart rate, RER, or blood lactate response were evident during the fixed-intensity exercise ($P > 0.05$). However, VO2, VE, and RPE values were all significantly increased at VT in the treatment group at 48 h following EIMD ($P < 0.05$). During the 15-minute time-trial, mean power output, distance covered, and VO2 during the time-trial were significantly lower in the treatment group at 48 h following EIMD ($P < 0.05$). Moreover, there was no significant interaction of time and group for RPE ($P>0.05$), suggesting that effort perception was unchanged during the time-trial in both groups following EIMD.

Discussion: We propose that the increased VE response was a sensory cue for the increased RPE during fixed-load exercise following EIMD. Furthermore, the increased VO2 following EIMD might have been evident to facilitate the rise in VE during fixed-intensity cycling. EIMD also impairs time-trial cycling through altering the sense of effort. Athletes should be aware of performing muscle-damaging exercise in the days preceding competition.

CHANGES IN THE RATE OF FORCE DEVELOPMENT MEASURED AT DIFFERENT MUSCLE LENGTHS FOLLOWING ECCENTRIC AND ISOMETRIC EXERCISE

PHILIPPOU, A., BOGDANIS, G.C., MARIDAKI, M.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

Introduction: The maximum rate of force development (RFD) has been shown to decrease after eccentric exercise (Crameri et al., 2007). However, there is little information regarding the changes in RFD when it is assessed at different lengths of the exercised muscle (RFD-length relationship). Besides, although muscle damage can also occur after isometric contractions at a long muscle length (Philippou et al., 2003), it is not known whether RFD is similarly affected after this form of exercise. The aim of this study was to examine the effects of isometric exercise at long muscle length on RFD-length relationship and to compare them with those presented after eccentric exercise.

Methods

Fourteen male volunteers, randomly divided into the eccentric (ECC, n=7) or the isometric (ISO, n=7) exercise group, performed 50 maximal voluntary eccentric, or isometric contractions at a long length of the elbow flexors of the non-dominant arm, on an isokinetic dynamometer. Peak isometric force (PIF) and time to peak force (TPIF) were measured at five different elbow angles, i.e., 50o, 70o, 90o, 140o, 160o, before and for 4 consecutive days post-exercise, and maximum RFD was determined as the PIF/TPIF ratio. Flexed (FANG) and relaxed (RANG) elbow angles and muscle soreness (DOMS) were also assessed at the same time points. Two-way ANOVA with repeated measures on one factor (day) was used for statistics.

Results: Both exercise protocols induced significant changes in the indirect markers of muscle damage post-exercise, i.e., DOMS, FANG and RANG, compared with baseline ($P<0.01$). Maximum RFD before exercise was higher at the elbow angle of 140o compared with 50o and 70o ($P<0.001$), while a similar RFD-length relationship was found in both groups. Maximum RFD was significantly decreased in both groups at all the angles tested in the days after the exercise regimens ($P<0.05$-0.001). The percent changes in RFD (i.e., normalized to pre-exercise values) were also significant in each group over time ($P<0.05$-0.001), but not between angles in any group or between groups.

Discussion: RFD-angle relationship was found to be similarly affected after both eccentric and isometric exercise at a long muscle length. The decreased RFD following muscle damaging exercise has been attributed to changes in cytoskeletal integrity and to an increase in the compliance of some muscle fibers (McCully and Faulkner, 1985; Crameri et al., 2007). However, the similar decreases in RFD at various muscle lengths found in the present study imply that other factors such as neuromuscular disturbances following muscle damage (Sayers et al., 2000) may also play an important role.

MRF RESPONSES IN THE ARM FLEXOR MUSCLES TO HIGH-FORCE ECCENTRIC EXERCISE

HANSSEN, K.E., PAULSEN, G., DRANGE, M., KADI, F., RAASTAD, T.

NORWEGIAN SCHOOL OF SCIENCES

Introduction: High-force eccentric exercise may result in muscle damage involving myofibrillar disruptions and in some cases segmental fibre necrosis. The repair processes may involve activation of satellite cells leading to satellite cell proliferation and later differentiation and fusion with other satellite cells or damaged myofibers. After activation, the proliferation and later differentiation of satellite cells are driven by the myogenic regulatory factors (MRFs). Consequently, the expression of MRFs can be used as markers of myogenic events during the course of activation of satellite cells (1). The purpose of this study was to investigate the MRF responses in the arm flexors after unaccustomed eccentric exercise and to a repeated bout three weeks later. We hypothesized that in the exercised arm the MRF levels would increase after bout 1, but after bout 2 the increase would be attenuated do to less damage in the repeated bout.

Methods: Thirty-three young males and females (23-28 years) participated. Seventy unilateral voluntary maximal eccentric actions with the arm flexors were performed twice (bout 1 and 2) with the same arm, separated by three weeks. The participants were randomized into a test and a control group. The exercise was performed with the same arm, randomly chosen, on bout 1 and 2. The other arm served as a non-exercised control. Nine days after the exercise bouts, tests of the force-generation capacity were performed. Biopsies from m. biceps brachii were collected from both exercised and control muscle 1, 48, 96, 168 hours after bout 1 and 1, 48 hours after bout 2. In order to visualize satellite cells cross sections were analyzed for immunoreactivity against CD56/NCAM (immunohistochemistry- IHC), and MRF protein content was determined using Western blotting.

Results:

The force-generating capacity measured as isometric torque was markedly reduced (-40-50%) after both exercise bouts. Long lasting recovery indicates muscle damage confirmed by other histological methods. So far only three subjects have been analyzed for MRFs and the preliminary results indicate that the MRF responses are according to our hypothesis. The rest of the samples will be analyzed the next months and the complete results on MRFs and satellite cells will be presented at the congress.

Discussion: In this study, the combination of IHC and Western blotting will give new information about the MRF response after a single bout of muscle damaging eccentric exercise and following a less damaging repeated bout of exercise.

THE EFFECT ON NEUROMUSCULAR JUNCTION FORM AND CONTRACTILE PROPERTIES IN THE RAT SKELETAL MUSCLE FOLLOWING THE ECCENTRIC CONTRACTION EXERCISE.

NISHIZAWA, T., YUKI, A., TAMAKI, H., KASUGA, N., TAKEKURA, H.

CHUKYO WOMEN'S UNIVERCITY JUNIOR NATIONAL INSTITUTE OF FITNESS AND SPORTS, KANOYA, AICHI UNIVERSITY OF EDUCATION

Introduction: The purpose of this study was to investigate the effect of the muscle damage by the exercise on neuromuscular junctions (NMJs) form and function in the rat skeletal muscle. In skeletal muscle after eccentric contractions, exercise induced muscle injury has been studied. Our studies so far have reported that significant changes in ultrastructural features of architecture of NMJs occurred in skeletal muscle fibers damaged by BPVC during the degeneration processes. And degradation of the ultrastructural features in NMJs occurred due to temporary denervation during muscle fiber degeneration processes. On the other hand, it is not clear the muscle damage by exercise causes the abnormality of the neuromuscular junction. In this study, we observed the degeneration processes of NMJs form following muscle fibers damages by eccentric contraction exercise. Additionally, the muscular contraction immediately after eccentric contraction exercise was measured.

Materials and methods

Female Fischer 344/Jcl rats (10 weeks old, body weight, 150–170 g) were used. All procedures in the animal experiments were performed in accordance with the guidelines presented in the Guiding Principles for the Care and Use of Animals in the Field of Physiological Sciences, published by the Physiological Society of Japan.

Training protocol: Downhill training ran on the treadmill continuously for 5min running with 2min rest interval, 18bouts at 40m/min and 16 degree decline. Downhill training it carried out once.

Contraction characteristic: Single muscle fibers were dissected from the extensor digitorum longus (EDL) muscles. Muscle contraction characteristic was measured after eccentric contraction exercise: 1,2,4,8,16,24,60 hours after exercise. The contraction characteristic developed by the nerve stimulation and by the muscle stimulation.

Morphological observation: We observed the degeneration of neuromuscular junctions on the muscle after eccentric-exercise: 1,2,4,8,16,24,60 hours after exercise. Three Types of fibers were classified based on differences ATPase activity. The muscle fiber composition is shown at muscle fiber for different types the number ratio. The morphological observation of neuromuscular junction by optical microscope used cholinesterase and silver staining.

Results: Significant changes in NMJs form occurred in skeletal muscle fibers damaged by eccentric contraction exercise. There was a difference in comparing indirect stimulation tension for the direct stimulation tension after exercise 4 hours. Significant changes was recognized after 16 hours. Significant changes Significant changes of both characteristics appeared after 16 hours. The muscle contraction characteristic was decreased, when the NMJs form is abnormal. It was indicated that the abnormal NMJs form was a factor of the decrease of the muscle contraction force.

EFFECTS OF TENDON VIBRATION ON DISCHARGE BEHAVIOR OF HUMAN MOTOR UNIT DURING SUBMAXIMAL ISOMETRIC CONTRACTION

KAMO, M.

JAPAN WOMEN'S COLLEGE OF PHYSICAL EDUCATION

Introduction

Discharges of motor units (MU) are well known to show elongating trends in the spike interval during voluntary constant-force isometric contraction (e.g. Kamo, 2002), but neural mechanisms underlying those trends remain unclear. A reduction in Ia afferent activity have been advanced as a possible cause the spike interval elongation (Macefield et al., 1991; Griffin et al., 2001). This study examined effects of manipulation of peripheral afferent by tendon vibration on elongating trends in spike interval of MU during the constant-force contraction.

Methods: Subjects voluntarily performed isometric knee extension with a knee angle of 90 deg at slightly above the recruitment threshold force of the single MU for 60 s (control experiment). Two other situations were used to manipulate (reduce and gain) afferent input by tendon vibration: (1) during the contraction after prolonged vibration (10min), and (2) during the contraction with vibration. The single MU activities in the control experiment, in which there was no intervention, were compared under two experimental situations. Action potentials of single MU were recorded in the vastus medialis muscle using non-invasive surface-array electrodes. Vibratory stimulation was applied perpendicularly to the patella tendon with 75 and 100 Hz frequency and 0.5-0.8 mm displacement.
Results: In the first situation, the spike interval of MUs elongated gradually during contraction, but the amount of the elongation was less than that in control experiment. In the second situation, the spike interval of MUs at the onset of constant-force contraction was significantly longer than that in the control experiment and subsequently shortened to the same interval as that in the control experiment at 30 s, but it began to elongate thereafter.
Discussion: Irrespective of peripheral afferent manipulation, the elongating trend in the spike interval did not disappear during the constant-force contraction. Results suggest that changes in neural input information to single MUs with peripheral afferent stimulation do not eliminate the spike interval's trend of elongation in the presence of voluntary drive.

CHANGES OF REST METABOLIC RATE AND BODY FAT RELATED TO 8 WEEKS WHOLE BODY VIBRATION TRAINING OF YOUNG FEMALE

KUEHNE, T., MISHCHENKO, V.
NEW LIFE BALANCE ACADEMY

New Life Balance GmbH, Roesrath, Germany1
Academy of Physical Education and Sport, Gdansk2

Recent study showed that intensity and duration of aerobic training should be gradually increased so that to maintain the effect of fat oxidation activation in long term health-related physical training. There is a reason to consider strength and whole body vibration training as one of the most perspective types of such training. However, its influence upon energy expenditures and activation of fat losses at rest needs further investigations. The aim was to determine the effects of 8-weeks of mainly strength physical exercises in combination with vibration impacts of inclined type upon rest metabolic rate and fatless body mass, girth of hips as well as cellulite manifestation in young females.

Thirty seven young females aged 20-25 years (students) without any contra-indications took part in the studies. Subjects of experimental group were used vibration platform (VP) LADIES-№1, whereas those of control group performed the same exercises using non-working VP. One medial-distal complete inclined vibration constituted 0..10 mm at frequency of up to 14 Hz. 24 training sessions (45-55 min) were performed in 8 weeks. Total duration of vibration load at one session constituted 8-12 min. The program of physical exercises designated as 'vibrobic' was performed. The exercises preferentially stimulated leg and trunk muscles as well as those of back. After 4 and 8 weeks were measured: rest metabolic rate (VO2), RQ, BMI, fatless body mass (FBM), and girth of two hips.

The results showed that resting oxygen uptake in group of vibration training increased for 8 weeks - from 2,85 (0,15) up to 3,14 (0,13) ml.kg-1.min-1 ($p<0.05$);. resting RQ in 24 hours after last exercises session decreased in the first 4 weeks vibration training only – from 0,841 (0,004) up to 0,819 (0,003) ($p<0.05$). FBM at the end of 8 week trainings was the greater in group of vibration training – 47.30 (2.27) vs 46.73 (2.72) ($p<0.05$), whereas initial values did not differ from control group. In overweight young women only (BMI 25 kg/m2 and higher, n=9) at vibration training took place decrease of BMI (from 26.07 (1.57) up to 24.89 (1.52) kg/m2) and % body fat (from 31.4 (1.4) to 29.0 (1.5) %.

The girth of two hips decreased for 8 weeks in group of vibration training (from 97.8 (3.2) to 96.4 (3.6) sm whereas in control group it did not differ from initial values. Visibility of cellulite of a back surface of two hips in 4 weeks in group of vibration training decreased from 470.4 (35.5) up to 413.4 (29.7) sm2 ($p<0.05$). In control group significant changes were for 8 weeks only.

We concluded that young female special physical training with whole body vibration stimulation induced increasing of rest metabolic rate. The main effects of decreasing in body fat have occurred faster and have been more expressed by the end of training program. It is determined by high potential of vibration stimulation associated with impacts of physical exercises for health-related female training.

INFLUENCE OF THE WHOLE BODY VIBRATION STIMULATION IN THE PROCESS OF HEALTH- RELATED PHYSICAL EXERCISE UPON STRENGTH CAPACITIES OF YOUNG FEMALES

MISHCHENKO, V., KUEHNE, T.
NEW LIFE BALANCE ACADEMY

Academy of Physical Education and Sport, Gdansk1
New Life Balance GMBH, Roesrath, Germany2

Introduction. Vibration physical exercises represent a new type of physical exercises the influence of which has been related to the idea of muscle additional stimulation according to mechanism of spinal reflexes (2). Vibration impacts create additional load on neuromuscular apparatus without significant influence upon subjective perception of tension. Meanwhile, application of vibration impacts for the whole body in the course of health-related training of females is somewhat restricted due to insufficient elaboration of the technology of vibration load application in combination with strength exercises. The aim of the study consisted in revealing the effects of 8-weeks mainly strength physical exercises in combination with vibration inclined type for the whole body upon strength capacities and fatless body mass of young females.

Methods. Thirty seven young females aged 20-25 years (students) without any contra-indications took part in the studies. Subjects of experimental group were used vibration platform (VP) LADIES-№1, whereas those of control group performed the same exercises using non-working VP. One medial-distal complete inclined vibration constituted 0..10 mm at frequency of up to 14 Hz. 24 training sessions were performed in 8 weeks. The program of physical exercises designated as VIBROBICA® was performed. .Strength type exercises preferentially stimulated leg and trunk muscles as well as those of back. Total duration of vibration load at one session constituted

8-12 min. After 4 and 8 weeks were measured: isometric strength (knee extensors); isokinetic strength and strength endurance (feet and arms); explosive strength (in jumps) and jumps endurance (1).
Results. The results showed the special effects of concomitant whole body vibration and physical exercises upon isometric, isokinetic, jumping strength and strength endurance. Augmentation of strength has been observed both in experimental and control group. However, in the group of vibration stimulation these effects have occurred faster and have been more expressed by the end of training program. Mean increasing of feet and arms extensors isokinetic strength for 4 weeks were 9.82 (1.9)% in experimental group meanwhile in control group 5.92 (1.8) for 8 weeks ($p<0.05$). There were no differences of increasing of jump endurance (4.10 vs 3.81%). In group of vibration stimulation strength capacities were increased especially during the first 4 weeks of training and has occurred without any expressed augmentation of active body mass.
Conclusion. We concluded that young female subjected to physical training with whole body vibration stimulation main effects have occurred faster and have been more expressed by the end of training program. The more essential effects were related to maximal and time development of strength and height of jump but not to endurance values.

MECHANICAL EFFICIENCY AND RUNNING ECONOMY IN OCCASIONAL AND SKILLED RUNNERS AND THEIR RELATIONSHIP WITH THE KINEMATIC VARIABILITY OF THE BODY CENTRE OF MASS

NARDELLO, F., GHEZZI, S., ZAMPARO, P., ARDIGÒ, L.P., MINETTI, A.E.
UNIVERSITY OF VERONA

Aim. The aim of this study was to investigate whether a significant relationship does exist between metabolic cost (C), "apparent" mechanical efficiency (η) and temporal (step duration) and/or spatial (three-dimensional displacement) variability of the body centre of mass (BCOM) in running. Our hypothesis is that skilled runners (SR) have a lower C, a higher η and a lower BCOM variability in respect to less experienced ones (OR). Material and methods. Fourteen healthy males were studied: 7 OR (33±13 yrs of age, 71±3 kg of body mass, 1.76±0.05 m of stature) training up to 2 hours per week and 7 SR (32±12 yrs, 67±6 kg, 1.77±0.04 m) training from 2 to 6 hours per week. A motion capture system (Vicon®, USA) was employed to record kinematic data at 100Hz. The 3D displacement of the BCOM was obtained [1] and the difference between the maximal and minimal value in a step was calculated in the x, y and z direction; the duration of each step was calculated as well. The variability of these parameters was assessed by calculating the coefficient of variation (CV) of over 10 consecutive running steps. Finally, mechanical work (W, J/(kg m)) was also computed [1]. Experimental protocol. Each subject was requested to run, on the level, at 5 incremental speeds (v, from 8 to 16 km/h) on a treadmill (h/p/Cosmos, G). During the experiments, oxygen uptake (V'O2) was measured by means of a portable metabograph (K4b2, Cosmed, I). C was calculated as net V'O2/v and expressed in J/(kg m). The "apparent" mechanical efficiency was calculated as the ratio W/C. Results. C was found to be lower (albeit not significantly) in SR (4.39±0.36 J/(kg m)) than in OR (4.51±0.39 J/(kg m)) and W was found to be larger ($p<0.01$) in SR (1.94±0.23 J/(kg m)) than in OR (1.77±0.22 J/(kg m)). The larger W in SR is associated with a significantly larger ($p<0.05$) vertical BCOM displacement (0.09±0.01 m) in comparison with OR (0.08±0.01 m); indeed: $W=1.38+5.52 \times BCOMv$, $n=70$, $r=0.52$, $p<0.001$. Finally η was found to be larger ($p<0.001$) in SR (0.44±0.03) than in OR (0.39±0.02). Significant relationships were found between C and/or η and the temporal and spatial (vertical and forward direction) variability of the BCOM: the higher the variability, the larger C and the lower η. Discussion. The "apparent" efficiency of running (η) is larger in SR than in OR and this has to be attributed to differences in W rather than in C. In turn, the observed differences in W can be attributed to differences in the "active stiffness" of the lower leg: the higher the stiffness, the larger the BCOM vertical displacement and hence the larger W (and η). Larger η values are also associated with a lower intra step variability (both spatial and temporal) of the BCOM. These findings could tentatively be explained by a more symmetrical gait pattern in skilled runners in comparison with occasional ones.

CHARACTERISTICS OF THE SUPPORT LEG MOVEMENT IN THE START AND TOP SPEED PHASES OF ELITE SPRINTERS

KIJIMA, K., FUKUDA, K., ITO, A., ISHIKAWA, M.
OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

Purpose:
The purpose of the present study was to examine the characteristic of the sprint start movement of elite sprinters.
Methods:
The measurement was performed at the 100-m event of the 11th IAAF World Championships in Athletics, Osaka, Japan. The movements of four male and three female elite sprinters, whose results were 9.85-10.20 sec in male and 10.99-11.98 sec in female, recorded by four high-speed cameras (200 fps) and analyzed with direct linear transformation method. The analysis phases were during start phase (6 steps from start) and middle phase (around the 60m from start). Their running velocity, step length, and step frequency as well as the angles of joints, segments and leg during the supporting phase. The peak angular, segment and leg swing velocities were calculated. The leg swing angle of the supporting leg was defined as the angle between a line from the trochanter major to the lateral malleolus and a perpendicular line from the trochanter major to the ground.
Results and Discussion:
The leg swing velocity and forward rotation velocities of the thigh and shank segments were higher with increasing steps. During the start phase, the forward rotation velocity of the thigh segment was already reached those during the middle phase. However, the forward

rotation velocity of the shank segment was significantly lower during the start phase than during the middle phase. Therefore, the leg swing velocity during the start phase can be obtained mainly due to the increment of the forward rotation velocity of the thigh segment. The previous study had reported that the knee joint during the foot contact phase should not be extended to transfer the hip extension velocity effectively to the leg swing velocity during the middle phase (Ito et al., 1998). During the start phase, however, the extension velocity of the knee joint and the amplitudes of the knee joint changes were greater in the start phase than in the middle phase. In addition, the angle of the shank segment was smaller as compared to that during the middle phase. It is likely that the elite sprinters could obtain the leg swing velocity by the knee extension due to the forward rotation of the thigh segment during the start phase.

THE RELATION ANALYSIS ON THROWING ANGLE AND MOTION IN JAVELIN THROW

TAZUKE, S.

DOSHISHA UNIVERSITY

Introduction: Throwing angle is important for better performance in track & field javelin throw. Javelin throwers tend to throw higher than optimal angle. Coach instructs athlete to throw lower, and thrower tries to throw the javelin lower. However, it is difficult for throwers to throw the javelin in lower angle. In this study the factors of the throwing angle in javelin throw were examined from the viewpoint of the throwing motions.

Methods: Subjects were 9 javelin throwers (aged 19.33 years+-1.414, best performance 55.75m+-8.047, career of javelin throw 48.22month+-1.563, body height 171.04cm+-8.042, body weight 68.39kg+-10.925), 2 female and 7 male throwers. The experiment was carried out from the throwing gate, which enables measuring the throwing angle, initial velocity and attack angle immediately, right after throwing. Subjects got their throwing angle after throwing from this gate. For the first throw, they threw the javelin normally. From the second to sixth throw, they were to declare their target throwing-angle beforehand, e.g. "higher" or "lower", those were recorded. Every throwing motion was filmed with two high-speed video cameras, film rate 250 / sec. by NAC. 21 out of 54 feasible throwing motions were analyzed by the three-dimensional analysis with motion analysis software, Dynas-3D by Shin-Osaka Shokai Co., Ltd. The correlation of the analyzed data, initial velocity of javelin (IVJ), velocity of body gravity (VBG), throwing angle (THA), attack angle (ATA), trunk angle (TRA), arm angle (ARA), arm-trunk angle (A-TA) and elbow angle (EA) etc. at release (R); last (LFC), second (SFC) and third foot contact (TFC) before releasing; third foot takeoff (TFT) before releasing were analyzed with the statistic software, SPSS.

Results and Discussion: A clear interactive relation was observed throwing angle and IVJ (r=-0.787, p=.01), VBG at R (r=-0.666, p=.01), THA on the XZ plane at TFT (r=-0.711, p=.01) and at TFC (r=-0.882, p=.01), TRA on the XY plane at TFC (r=0.642, p=.05), TRA on the XZ plane at R (r=0.593, p=.05) and SFC (r=0.700, p=.01), ARA on the XY plane at R (r=0.585, p=.05), and ARA on the XZ plane at SFC (r=0.552, p=.05), at TFT (r=0.803, p=.01) and at TFC (r=0.724, p=.01), and left ARA on the XY plane at R (-0.597, p=.05), at LFC (r=-0.787, p=.01) and at SFC (r=0.795, p=.01), left ARA on the XZ plane at RFC (r=0.550, p=.05) and at TFT (r=0.623, p=.05), A-TA at LFC (r=0.754, p=.01), TRA on the ZY plane at R (r=0.700, p=.01) and at TFT (r=0.561, p=.05).

3 followings were mainly suggested from the experiment. 1) When the direction of javelin leans toward X axis at TFC, the throwing angle is lower. 2) When the trunk leans toward horizontal line at TFC, the throwing angle is higher. 3) When the throwing arm leans toward horizontal line at R, the throwing angle is higher.

BIOMECHANICAL ANALYSIS OF SPRINT RUNNING MOVEMENT OF ELITE SPRINTERS: THE THIGH AND SHANK SEGMENT'S MOVEMENT DURING THE CONTACT PHASE

FUKUDA, K., KIJIMA, K., ITO, A.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

Purpose:

The purpose of the present study was to examine the characteristics of lower limb's movements around the top sprint speed phase of elite sprinters. Especially, it focused on the movements of the thigh and shank segments during the contact phase.

Methods:

The subjects were 6 male (9.85-11.24 sec) and 6 female (10.99-13.10 sec) sprinters, who participated in a 100-m races in 11th IAAF World Championships in Athletics, Osaka, Japan. Their running movements of one stride at approximately 60-m point were recorded by two high-speed video cameras (200fps) and calculated the following parameters with three-dimensional direct linear transformation method: average running velocity during the one stride, step length and step frequency as well as the average segment and joint angles of legs during the contact phase. The contact phase was divided into the ratio of 43% and 57% as the deceleration and acceleration phases, respectively. These phases were defined by the previous study (Fukuda et al., 2004) which calculated from the horizontal components of the ground reaction forces.

Results and Discussion:

The average angular velocity of the shank segment during the deceleration and acceleration phases were positively related to their running velocity. In these subjects, the average angular velocity of the shank during the deceleration phase was slightly higher than that of the thigh. It is likely that the greater forward rotation velocity of the shank segment could be occurred by the deceleration force of the initial impact. Consequently, the angular velocity of the knee joint showed a flexor direction during the deceleration phase. During the acceleration phase, on the other hand, the average angular velocity of the thigh segment increased, especially for the lower sprint velocity group, and did not showed any significant difference with that of shank segment. However, the average angular velocity of shank segment decreased similarly to all of them from the deceleration to acceleration phase. Consequently, the knee joint extended during the acceleration phase in the lower sprint velocity group. These results suggest that the elite sprinters can be hardly extended of the knee during the acceleration phase due to the greater angular velocity of shank segment. This is likely that elite sprinters could be transferred angular velocity of thigh segment effectively to the leg swing velocity.

INITIAL ROTATIONAL VELOCITY OF HIPS IS A KEY FACTOR IN DISCUS THROW

YAMAMOTO, D., ITO, A.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

The purpose of this study was to investigate relationships between the official discus throwing distance and the movements of discus throw or the release conditions of discus. The throwing movements of 18 male discus throwers were recorded by two digital video cameras (60 Hz) in the 11th World Championships in Athletics in Osaka and the Japan Track and Field National Championships, and also in experimental trials. From the video data of trials when each athlete had thrown the longest distance, real-life three-dimensional coordinates of their body landmarks and the center of the discus were calculated with the direct linear transformation method. The throwing movements were divided into six instants and analyzed.

The initial velocity and the height of discus at the moment of release showed a positive correlation with the throwing distance. The throwing distance had no relation with the release height normalized by the body height and the release angle. These results suggested that the initial velocity and the release height of discus must be important to take longer throws, however the release height was dependent on the body height. At the right-foot takeoff (R-off) and the left-foot touchdown (L-on), both discus velocity and rotational velocity of hips indicated positive correlations with the throwing distance. Positive relations were shown between the discus velocity at R-off and rotational velocity of shoulders and hips at the same instants. The discus velocity at L-on had a positive relationship with the rotational velocity of shoulders at that time. The higher discus velocity at R-off of longer-distance throwers suggested that increase of rotational velocity of the whole body at the beginning of throwing movements is important. The translational velocity of the center of mass including thrower and discus (CM) at left-foot takeoff (L-off), right-foot touchdown (R-on) and L-on were recognized as a negative correlation with the official distance. The translational velocity of CM showed a negative relation with the rotational velocity of hips at L-off, and also velocity of CM indicated a negative correlation with torsion angle of trunk at R-on. These results suggested that longer-distance throwers might keep lower translational velocity of CM to obtain lager torsion angle of trunk during the flight phase.

These findings were concluded as follows. Differences in movements which determine throwing distance appeared from the beginning of throwing movements. That is, it is necessary for throwers to increase discus velocity with rotational velocities of shoulders and hips from the initial phase of throwing. At the middle phase, to maintain a lower translational velocity of CM must obtain higher rotational velocity of hips, and thus a larger torsion angle of trunk is produced by the higher rotational velocity of hips. The increase of rotational velocity of hips, shoulders and arm swing occurred in order during the final phase before discus release.

FOOT STRIKE PATTERNS OF HIGH LEVEL MALE 800M RUNNERS

HAYES, P.R., CAPLAN, N.

NORTHUMBRIA UNIVERSITY

Recently Hasegawa et al (2007) investigated the foot strike patterns and ground contact times during a half marathon. They found that foot strike patterns were related to running speed with forefoot and midfoot strikers exhibiting shorter ground contact times and faster running speeds. The purpose of this study was to conduct a similar analysis in male 800m runners. Ten seeded sub-elite races were filmed on one evening at a British Milers Club meeting. Seventy one runners were filmed by a 100-Hz video camera at a height of 15 cm placed 15 m from the start / finish line. All runners completed their race and were captured on both laps of the race. Average race time showed a range of 14.46 s from 107.53 to 121.99 s with a mean 115.21 +/- 3.41s and coefficient of variation of 3.0%. The mean contact time for lap 1 was 156 +/- 12 ms and for lap 2 it was 168 +/- 16 ms. On lap 1 35%, 48% and 17% of runners made initial ground contact with the forefoot, midfoot and heel respectively. For lap 2 these values were 34%, 51% and 15%. Two way ANOVA s comparing ground contact time across the different races for lap 1 and lap 2 revealed significant main effects for both lap ($F_{1,61} = 46.315$; $P < 0.000$) and race ($F_{9,61} = 2.766$; $P = 0.009$). Those runners who displayed the same foot strike pattern on both laps ($N = 48$) were entered in to a 2x3 ANOVA comparing ground contact times by lap and foot strike position. This showed significant main effects for both lap ($F_{1,45} = 32.600$; $P < 0.000$) and foot strike position ($F_{2,45} = 12.779$; $P < 0.000$). Post-hoc analysis revealed significant differences between the heel and both other contact points. The shortest ground contact times were for the forefoot (156 ms) followed by midfoot (161 ms) and heel (177 ms). For each contact point there was a significant increase (forefoot – $t_{15} = 2.782$, $P = 0.014$; midfoot – $t_{24} = 3.501$, $P = 0.002$; heel – $t_{8} = 5.292$, $P = 0.001$) in ground contact time between lap 1 and lap 2. Linear regression revealed a significant relationship between average running speed and ground contact time for both lap 1 and lap 2, however only a small portion of average running speed was accounted for (10.3% lap 1 and 11.9% lap 2). This study found that foot strike patterns were related to running speed. The relationship between ground contact time and running speed supports the notion of a spring-mass model of locomotion. Over the course of an 800m race ground contact time increased irrespective of foot strike position. This implies an element of fatigue, with runners presumably requiring longer to generate the same impulse. Alternatively, this may have been a reflection of the pacing strategy during the races, with all races adopting a first lap that was quicker than average race speed.

FOOT STRIKE PATTERNS OF HIGH LEVEL FEMALE 800M RUNNERS

HAYES, P.R., CAPLAN, N.

NORTHUMBRIA UNIVERSITY

Recently Hasegawa et al (2007) investigated foot strike patterns and ground contact times during a half marathon. They found foot strike patterns were related to running speed with forefoot and midfoot strikers exhibiting shorter ground contact times and faster running speeds. The purpose of this study was to conduct a similar analysis in female 800m runners. Five seeded sub-elite races were filmed on one evening at a British Milers Club meeting. The runners ($N = 34$) were filmed by a 100-Hz video camera at a height of 15 cm placed 15 m from the start / finish line. All runners completed their race and were captured on both laps of the race. Average race time showed a range of 15.85 s with a mean 132.84 +/- 4.43 and CV of 3.3%. Mean contact time for lap 1 and lap 2 were 163 +/- 14 ms and 179 +/- 16 ms. On lap 1 27%, 44% and 29% of runners made initial ground contact with the forefoot, midfoot and heel respectively. These values

were essentially unchanged at 27%, 41% and 32 % on lap 2. An ANOVA comparing ground contact time across the different races for both laps revealed significant main effects for lap ($F_{1,29} = 35.445$; $P < 0.000$) and race ($F_{4,29} = 6.112$; $P = 0.001$). Runners displaying the same foot strike pattern on both laps (N = 27) were entered in to a 2x3 ANOVA comparing ground contact time by lap and foot strike position. This showed significant main effects for lap ($F_{1,24} = 28.707$; $P < 0.000$) and foot strike position ($F_{2,24} = 4.299$; $P < 0.025$). Post-hoc analysis revealed significant differences between heel and forefoot strikers. The shortest ground contact times were for the forefoot (167 ms) followed by midfoot (172 ms) and heel (181 ms). Both forefoot and midfoot strikers exhibited a significant increase (forefoot – $t6 = 5.435$, $P = 0.002$; midfoot – $t10 = 4.038$, $P = 0.002$) in ground contact time between laps. Heel strikers showed no significant increase in ground contact times across the two laps (heel – $t8 = 1.692$, $P = 0.129$). Linear regression revealed a significant relationship between average running speed and ground contact time for lap 1, lap 2 and average contact time. Only a moderate portion of variation in average running speed was explained (29.9 %, 25.6 % and 36.9% for lap 1, lap 2 and average contact time respectively). This study found that foot strike patterns were related to running speed. The relationship between ground contact time and running speed supports the notion of a spring-mass model of locomotion. Over the course of an 800m race ground contact time increased. This implies an element of fatigue, with runners presumably requiring longer to generate the same impulse. Alternatively, this may be a reflection of the pacing strategy during the races, with all races adopting a first lap that was quicker than average race speed.

FOOT STRIKE PATTERNS OF HIGH LEVEL FEMALE 1500M RUNNERS

CAPLAN, N., HAYES, P.

NORTHUMBRIA UNIVERSITY

Recently Hasegawa et al (2007) investigated the foot strike patterns and ground contact times during a half marathon. They found that foot strike patterns were related to running speed with forefoot and midfoot strikers exhibiting shorter ground contact times and faster running speeds. The purpose of this study was to conduct a similar analysis in male 800m runners. Two seeded sub-elite female 1500 m races were filmed on one evening at a British Milers Club meeting. Twenty four runners were filmed by a 100-Hz video camera at a height of 15 cm placed 15 m from the start / finish line. All runners completed their race and were captured on all four laps of the race. Average race time showed a range of 46.21 s from 254.66 to 300.87 s with a mean 272.04 +/- 10.63 s and coefficient of variation of 3.9%. The mean contact time for laps 1 – 4 was 172 +/- 12 ms, 178 +/- 16 ms, 186 +/- 16 ms and 185 +/- 20 ms. On lap 1 20.8, 50.0 and 29.2% of runners made initial ground contact with the forefoot, midfoot and heel respectively. For lap 4 these values were 25.0, 41.7 and 33.3%. A two way ANOVA comparing ground contact time across the different races for each lap revealed significant main effects for lap ($F_{3,66} = 12.367$; $P < 0.000$) but not race ($F_{1,22} = 2.151$; $P = 0.151$). Those runners who displayed the same foot strike pattern on both laps (N = 18) were entered in to a 4x2 ANOVA comparing ground contact times by lap and foot strike position. This showed significant main effects for each lap ($F_{3,45} = 7.014$; $P < 0.001$) and foot strike position ($F_{2,15} = 4.372$; $P < 0.032$). Post-hoc analysis revealed significant differences between the heel and midfoot contact points. The shortest ground contact times were for the midfoot (174 ms) followed by forefoot (179 ms) and heel (196 ms). Lap 1 had shorter ground contact times than any of the other three laps. Linear regression revealed a significant relationship between average running speed and average ground contact time however only a moderate portion of average running speed was accounted for (23.8%). This study found that foot strike patterns were related to average running speed. The relationship between ground contact time and running speed supports the notion of a spring-mass model of locomotion. Over the course of a 1500m race ground contact time increased irrespective of foot strike position. This implies an element of fatigue, with runners presumably requiring longer to generate the same impulse. Alternatively, this may have been a reflection of the pacing strategy during the races, with all races adopting a first lap that was quicker than average race velocity.

FOOT STRIKE PATTERNS OF HIGH LEVEL MALE 1500M RUNNERS

CAPLAN, N., HAYES, P.

NORTHUMBRIA UNIVERSITY

Recently Hasegawa et al (2007) investigated the foot strike patterns and ground contact times during a half marathon. They found that foot strike patterns were related to running speed with forefoot and midfoot strikers exhibiting shorter ground contact times and faster running speeds. The purpose of this study was to conduct a similar analysis in male 1500m runners. Five seeded sub-elite races were filmed on one evening at a British Milers Club meeting. Fifty two runners were filmed by a 100-Hz video camera at a height of 15 cm placed15 m from the start / finish line. All runners completed their race and were captured on all four laps of the race. Average race time showed a range of 37.65 s from 225.34 to 262.99 s with a mean 236.91 +/- 8.83 s and coefficient of variation of 3.7%. The mean contact time for laps 1 – 4 was 167 +/- 16 ms, 172 +/- 17 ms, 175 +/- 17 ms and 176 +/- 19 ms. On lap 1 34.6, 46.2 and 19.2% of runners made initial ground contact with the forefoot, midfoot and heel respectively. For lap 4 these values were 36.5, 36.5 and 27.0%. Two way ANOVA s comparing ground contact time across the different races for each lap revealed significant main effects for both lap ($F_{3,141} = 12.109$; $P < 0.000$) and race ($F_{4,47} = 3.863$; $P = 0.009$). Those runners who displayed the same foot strike pattern on both laps (N = 44) were entered in to a 4x3 ANOVA comparing ground contact times by lap and foot strike position. This showed significant main effects for each lap ($F_{3,123} = 6.694$; $P < 0.000$) and foot strike position ($F_{2,41} = 23.132$; $P < 0.000$). Post-hoc analysis revealed significant differences between the heel and both other contact points. The shortest ground contact times were for the forefoot (161 ms) followed by midfoot (169 ms) and heel (192 ms). Lap 1 had shorter ground contact times than any of the other three laps. Linear regression revealed a significant relationship between average running speed and ground contact time for all four laps and average contact time, however only a moderate portion of average running speed was accounted for (24.8 – 34.9%). This study found that foot strike patterns were related to average running speed. The relationship between ground contact time and running speed supports the notion of a spring-mass model of locomotion. Over the course of a 1500m race ground contact time increased irrespective of foot strike position. This implies an element of fatigue, with runners presumably requiring longer to generate the same impulse. Alternatively, this may have been a reflection of the pacing strategy during the races, with all races adopting a first lap that was quicker than average race velocity.

PP-CO02 Coaching 2

THE MEETING IN A SUCCESSFULLY COACH-ATHLETE RELATIONSHIP

JOHANSEN, B.T., SVELA, A.E.

UNIVERSITY OF AGDER

Introduction: The purpose of this study was to investigate the meeting that take place in professional coaching in a coach-athlete relationship, all facets related to the process leading up to a successfully coach-athlete relationship (Jowett, 2008), communication in the relationship, type of leadership, and factors related to their satisfaction with performance and instruction of their coach-athlete relationship.

Method

Due to the two different types of sports that exist, individual and team sports, two different coach-athlete relationships were included in this study, but only results from the team dyad will be presented in this paper. The team sport coach and athlete are performing at top national level in football, and the dyad is respectively the head coach and the captain of the team. They share a history of three years together. The coach is 42 years of age, coaching experience from top national level for eight years with national cup trophy in 2000. The athlete is 35 years of age and has been playing at top national and international level for more than fifteen years.

In-depth interviews were conducted and arranged to take place individually. An interview guide was used for gathering data and an Ipod recorder was used during the interview. Both interviews lasted for approximately 1 hours and 10 minutes.

The analyses of the data obtained followed a phenomenological procedure (Aanstoos, 1983) trying to grasp and identifying meaning units, specifying central themes, and then articulating their psychological sense or meaning in order to examine the nature of the meeting in a successfully coach-athlete relationship.

Results: Results from interviews with both the coach and the athlete in the team sport coach-athlete relationship indicated that factors such as social support, commitment, humor, use of time, attention, and carefulness are all important facets for the dimension building a successfully relationship. In the dimension communication vital facets appear to be thoroughly, the frequency, the consistency between verbal and non verbal communication, and the art of the informal communication during everyday practice. For the dimensions leadership and performance and instruction it seems to be respectively consistency for the coaching process, and focus on the impact of intrinsic motivation (Jowett, 2008) and evaluation of own development as most important.

Discussion: In general both the coach and the athlete underlined the significance of consistency and commitment for a successfully relationship in order to perform in sport. The study also revealed that communication and democratic leadership is vital factors for the meeting in the relationship for both the coach and athlete to grow and develop which is in line with former research.

LEADERSHIP BEHAVIORS AND COACH-ATHLETE RELATIONSHIPS IN SCANDINAVIAN COACHES

JOHANSEN, B.T., CHRISTENSEN, J.B., ENOKSEN, E., FAHLSTRÖM, P.G., HAGESKOG, C.A., HØIGAARD, R.

UNIVERSITY OF AGDER

Introduction: The purpose of the study was to investigate in a sample of Scandinavian elite coaches, the relationship between perceptions of their own leadership behavior and their perception of the coach-athlete relationship.

Method

149 elite coaches (e.g. national top and/or international level) from Denmark (n=50), Norway (n=50) and Sweden (n=49) participated (134 male, mean age 38.3±9.8yrs; 15 female, mean age 39.1±8.4). 58 percent of the coaches were coaches of individual sports and 42 percent were coaches of team sports. 59 percent of the participants had at some point, undertaken academic study related to sport at university level. A paper-copy questionnaires were distributed by post to all coaches listed in each country's athletic federation index.

Leadership behaviour: Coaches self reported their perceptions of their own leadership behaviors using the Leadership Scale for Sport (Chelladurai & Saleh, 1980). The Cronbach's alpha for self reported leadership behavior was: .79 training and instruction, .59 positive feedback, .66 social support, .78 democratic behavior, and .46 autocratic.

Coach-athlete relationship: The nature of the coach-athlete relationship was evaluated using the 13-item Nordic Coach–Athlete Relationship Questionnaire (NOR-CART-Q; Jowett & Ntoumanis, 2003). The Cronbach's alpha for closeness, commitment, and complementarity was .83, .72 and .67 respectively.

Results: Positive feedback, training and instruction, and democratic behavior were the most frequent self-reported behavior subscales amongst the coaches. Moreover, it is a positive relationship between commitment and training and instruction ($r=.25$, $p < 0.01$) positive feedback ($r= 22$, $p < 0.01$) and social support behavior($r=.22$ $p < 0.01$). Complementarity was positively related to training and instruction behavior ($r=.17$, $p < 0.01$). Multilevel logistic regression analyses indicated a significant difference between coaches in Denmark and Sweden on commitment (5.39 vs. 5.95) and complementarity (5.82 vs. 6.26) and coaches who are educated in sport use more positive feedback (4.25 vs. 4.41). Moreover, coaches with more than 10 years experiences in coaching us significantly more training and instruction (3.65 vs. 3.82) and social support (3.02 vs. 3.23) than coaches with less experiences. Furthermore, coaches in individual sport reported more democratic behavior (3.80 vs. 3.23) and less autocratic behavior (2.56 vs. 2.78) then coaches in team sport.

Discussion: In general coaches with more experience and more sport education used more positive feedback and social support. The study also revealed differences in leadership behavior between individual and team sport which is in line with former research.

THE PENALTY IN FOOTBALL

VICENTE, A., FERNANDO, C., LOPES, H., ALMADA, F.

UNIVERSITY OF BEIRA INTERIOR, UNIVERSITY OF MADEIRA, VML LTD.

INTRODUCTION: The penalty is important in a football game, because of the percentage of achieved goals, and since through them the tie situations can be resolved. It is known by "the lottery'.

We reject, however, these statements, because in previous studies we've found that, considering 8 possible directions (1 - initial position, 2 - up, 3 other – right: high, medium low and, 3 more identical to the left) for the goalkeeper to displace in order to defend the ball, in more than 40% of the situations, they've chosen the correct direction (even arriving late), which would not have been possible if the decision was purely random.

The question we ask, to diagnose and prescribe training situations with greater intentionality, is: which variables settle the success in a penalty?

METHODS: We've analyzed 250 penalties, through image digitization of video, football games of the FIFA and UEFA top competitions over the last 10 years.

Knowing the space (e) that the ball should travel to the goal (11m), the goal dimensions (2.44mx7,32m), that one second of film contains 25 frames (0,04 seconds), we measured the time the goalkeepers took to move up to intercept the ball, the time that the ball took to reach the goal or be intercepted, the moment when the goalkeeper started his displacement in relation with the kick, and the ball average speed

We've also defined, in the situations that haven't ended in goal, what corrections should be made into the striker to be successful.

We've made the same analysis for the goalkeepers in situations where they could not avoid the goal.

In this sense, we've defined what corrections should be made and when these could result in success for both the striker and the goalkeeper.

After making the sequence we've functionally defined what was happening in each penalty.

RESULTS: From the 250 penalties analyzed, we've seen that:

- 157 (62,8%) were scored;
- The other 93 (37,2%) weren't scored. From theses, 44 were intercepted by the goalkeeper (47,3%) and in the other 49 the ball was not kicked in the goal direction (52,7%).
- We've also get that:

• the goalkeepers reaction time was at least 0,7 seconds (complex reaction time)

• the ball time to reach the goal even varied between 0,4 and 1,2 seconds was only higher that 0,6 seconds when the goalkeeper was already out of balance when the ball was kicked.

• the goalkeepers started their displacement, in average, 0,4 seconds before the ball was kicked.

• in 47% of the situations the goalkeepers moved in the ball direction.

DISCUSSION: Although the penalty is not a purely random situation, despite the great variability of situations and values for the different variables involved, we've set a time where key decisions are taken either to the goalkeeper and the striker.

This is the time for the kinetic energy accumulation of the movement of different segments used in the kick. At this stage there is an inverse relationship between the acceleration time and the speed that the ball can reach.

DO ELITE COACHES UNDERSTAND SPORT SCIENTISTS? – A STUDY ABOUT THE USEFULNESS OF RESEARCH DATA

ESTEVES, D., PINHEIRO, P., BRÁS, R., O'HARA, K.

UNIVERSIDADE DA BEIRA INTERIOR

Despite the abundance of scientific literature, databases and electronic papers concerning sport sciences (Lippi et al., 2008), there is a general perception that coaches lack operative data to the decision making process (Midgley et al., 2007), that is the major task of the sport training process (Abraham et al. 2006). In this sense, we came to a paradox: the amount of available data may not correspond to the enhancement of sport performance during training process. This paradox may be related to a data overflow problem (Liautaud & Hammond, 2000).

Under the scope of contributing to minimise that "gap" between research and coaching practice, this work aims (1) to evaluate the usefulness of research data, concerning the needs of the coaches and (2) to propose some major solutions to minimise this problem.

This study used a survey to evaluate the perceptions of 47elite coaches in Portugal regarding both the usefulness of data in scientific literature and data overflow problem. Results show that elite coaches lack operative data, or because they perceived is not available for ecologic training process, or it is available but not in an "adequate", understandable language.

Among this investigation, we reach several major conclusions: (1) data overflow may be a problem in sport sciences; (2) to do a proper use of available data, it is necessary the implementation of mechanisms in data's search, selection and treatment, according to Information Management Theory (Eppler & Mengis, 2004; Savolainen, 2007) and (3) research results in sport sciences must be oriented to the training process, and transmitted more efficiently to the coaches (similar results were pointed out by Williams & Kendall, 2007).

THE FEINT IN FOOTBALL

VICENTE, A., LOPES, H., FERNANDO, C., ALMADA, F.

UNIVERSITY OF BEIRA INTERIOR, UNIVERSITY OF MADEIRA, VML LTD.

INTRODUCTION: In football training to be able to identify the variables involved in a feint makes it possible to do specific corrections in the action of a player, even if it is a higher level one (but not only), because it allows diagnosing the cause of the error and what can be most useful to train, prescribing exercises that require more emphasis on the improvement of relevant aspects and not the generality of the situation, and even to control the progress that is being achieved through the measurement of the evolution that is happening in the factors trained.

So, it's increased the profits yield because the training is directed to the important aspects in that situation for that player.

METHODS: We've analyzed 276 feint situations through image digitization of videos from high competitive level football matches of clubs and national teams.

In the analysis were considered the time of each frame (0.04 seconds) and the relationship established between the stimuli that were provided by the player who made the feint and the response of the opponent.

We've considered also as a point of reference of minimum reaction time 0.4 seconds.

We've found in 134 of analyzed situations, those that were not successful, what corrections should be made to avoid the error.

In all feints we've analyzed the relation between the two players and the corrections that each could make to improve his performance.

We've also analyzed a number as high as possible of the same situations from the same players, and also in these sets of situations obtain successful as well as missed feints.

RESULTS: From the 276 analyzed situations we've obtained the following distribution:

- Total of players analysed 35
- From this 35 players, 26 of them have a sample of 10 feints with an average of 6 succeeded and 4 missed.
- From the other 9 players we have a percentage of 12,8 feints from each one being 30 of them missed.

We've seen that the successful feints were not the ones with shorter execution time, on the contrary, in 76% of them, they were significantly slower that the identical feints from the same player than the feints that were missed.

When considering what corrections should be made, was considered that the action of the opponent who made the cut would be the same and found that in 91% of cases if the player action had been slower (taking into account that the opponent's position would be the same) that he would had naturally succeeded.

DISCUSSION: The success of a feint is not dependent of the speed with which it is made but in the effect it is possible to obtain in the opponent and the ability of the player who will perform the feint has to wait for the signal that sends to the opponent will make effect before changing his action to what he must to do.

The feint, as we set, 'is played' in times of decision making and reaction times of both players.

PP-HF04 Health and Fitness 4

EFFECTS OF A CORPORATE FITNESS PROGRAM UPON EMPLOYEES OF DIFFERENT AGE RANGES

MELLO, A.

FEDERAL UNIVERSITY OF RIO DE JANEIRO

Introduction: Competitiveness of globalized markets demands, besides quality products, the attention of business companies to the environment, safety and health, differentials of great relevance. Among many initiatives, companies have implemented corporate fitness programs aiming the health and the fight against their employees' chronic degenerative diseases (OPS/OMS, 2005), promoting decrease in absenteeism and in early retirement. In Brazil, Petrobras – Petróleo Brasileiro S/A, in its CENPES unity located in Rio de Janeiro, offers a physical conditioning program (bodybuilding, gymnastics and stretching) to its employees at the Espaço Bem-Estar wellness center.

Methods: The aim of the present study was to investigate possible impacts on the employees' health who participated in the program, according to four different age ranges. The sample consisted of 107 users of both genders and the following variables were investigated: Weight, Body Mass Index (BMI), Fat Percentage (%Fat), Lean Body Mass (LBM), Flexibility and Maximum Volume of Oxygen (VO2maximum). Individuals were assessed in two moments: 1- Before the beginning of the activities in the program and 2- After six months of enrollment. The Exploratory Data Analysis technique was applied to the treatment of rough data and verification of the adherence variables to the normal curve (NIST/SEMATECH, 2006). The parametric t-test, two paired samples for the means, was applied for comparison of the means and identification of the differences. Statistical analysis was conducted using the Statistica 6.0, R 2.4.1 and Microsoft Excel 2003 softwares.

Results: Frequency distribution demonstrated the following behavior: between 20<x≤30 years of age were 22.43% of the participants, between 30<x≤40, 29.91%, between 40<x≤50, 38.32% and over 51, 9.35%. Results indicated that at the age range of 20<x≤30 there was an increase in LBM and in Flexibility in the comparative analyses conducted before and after six months in

the program at a 5% significance level. In 30<x≤40 there was a reduction in %Fat and increase in Flexibility. The 40<x≤50 age range was the most significant in the study because all variables underwent positive changes, except for Flexibility. Over 51 years of age it was observed an increase in VO2maximum.

Discussion: The results of the study showed that the fitness program resulted in benefits to the employees' health, be it in the LBM increase, %Fat decrease, Flexibility increase or VO2maximum, but benefits may vary according to age ranges. Youths tend to improve Flexibility more, whereas the employees over 40 improve VO2maximum more.

CORPORATE FITNESS AND NUTRITION AS AGENTS IN THE REDUCTION OF RISK FACTORS FOR NON-TRANSMISSIBLE CHRONIC-DEGENERATIVE DISEASES

MELLO, A.

FEDERAL UNIVERSITY OF RIO DE JANEIRO

Introduction: Public institutions and business companies are concerned about non-transmissible chronic degenerative diseases (NTCDD) as arterial hypertension, cardiovascular diseases and diabetes mellitus. Petrobras, a Brazilian company of oil and gas, has created policies of prevention and control of its employees' health and founded the Center for Health Promotion/ CHP [Centro de Promoção de Saúde] in its main building in Rio de Janeiro, integrating fitness performed every week and regular food guidelines. The aim of this study was to verify possible alterations in the risk factors for NTCDD in groups of participants in the program at the CHP after the period of a year of activities, according to the week frequency to the program.

Methods: The functional and biochemical profiles of a sample composed of 357 employees were assessed, selected according to the presence of risk factors for NTCDD through an annual medical exam. The sample was divided into three groups: employees with frequency (F) to the program of physical exercise ≥ twice a week (G1, n=59); F = once a week (G2; n=115); and assessed employees who did not join the program (G3; n=215). All were submitted to the initial anthropometric and nutritional assessment but only G1 and G2 had all the variables re-assessed. Total body mass, relative body fat (%F), waist perimeter (WP) were assessed. We considered hypertensive individuals those who presented systolic blood pressure (SBP) ≥ at 140mmHg, and/or diastolic blood pressure (DBP) ≥ at 90mmHg. The biochemical variables were composed by the assessment of fast glycemia and determination of the lipid profile (triglycerides, total cholesterol, LDL and HDL). We determined the prevalence of the Metabolic Syndrome (SM) according to criteria established by the American Heart Association (2005). For the statistical analysis we used the two way-ANOVA in the SPSS 13.0 program, with 0.05 significance level.

Results and Discussion: As regards the lipid profile, we observed a reduction in all the assessed fractions where were highlighted the decrease in LDL (G1 males: 139.4 vs. 112.9 mg/dl and G1 females: 130.6 vs. 117.7 mg/dl); (G2 males: 133.5 vs. 117.8 mg/dl and G2 females: 134.9 vs. 103.7 mg/dl) ($p < 0.05$); G3: (G3 males: 134.5 vs. 122.3 mg/dl and G3 females: 123.1 vs. 117.3 mg/dl ($p > 0.05$). We observed the maintenance of the MS percentage among the females in G2, and a statistical significant increase in the female participants in G3 (50% vs. 100%). Among males, there was a decrease in MS in G1 (50% vs. 39%) and an increase with statistical significance in G3 (50% vs. 100%). As regards the glycemic profile, there was a good control of the levels of serum glucose, as in G1 as in G2, and a tendency of increase in G3. There were statistically significant reductions in SBP, DBP, %F and WP in physically active individuals. Even with low weekly frequency to the fitness and nutrition program participants obtained benefits in the reduction of risk factors for NTCDD.

ELDERLY WORKERS IN PHYSICALLY DEMANDING JOBS: HOW DO THEY MANAGE?

JEBENS, E., MEDBØ, J.I., MAMEN, A., KNUTSEN, O.

NATIONAL INSTITUTE OF OCCUPATIONAL HEALTH

Introduction: Work in the construction industry is physically demanding and influence the workers' physical and psychological resources. Musculo-skeletal disorders constitute the most common diagnose for disability pensions in the trade. The construction industry is the second largest branch for disability retire¬ment for the age group 60–64 yr. This supports the concept that may be called the "strenuous work hypothesis". Senior construc¬tion workers that report lasting health problems or feel they are so worn out that their work ability is considerably reduced, have the largest tendency to retire early.

Physical ability is reduced by age. A common and important misunderstanding is that workers with physically demanding tasks assume that they maintain their physical work ability through their work. This may not be correct. Therefore, elderly workers may be at disadvantage in physically demanding job.

The purpose of this study was to examine conditions that may retain the seniors (50+ yr) in working life until they reach the age of normal retirement of 67 year (national insurance).

Methods: First a survey (questionnaires) was carried out among all employees in a medium-sized construction company (n = 100). Thereafter 40 construction workers (20 above 45 yr, 20 below 30 yr) were tested for muscular strength, cardio-respiratory fitness, and body fatness. Moreover, 18 of the older and 12 of the younger workers were followed for 1 h each during their normal work while oxygen uptake and heart rate were measured continuously by automatic analysers.

Results

Having good health / not being worn out was reported as the most important requirement for staying in work to normal age of retirement. Moreover, most of the workers stated that the work was medium to very strenuous, that they had demanding working positions and that they had daily handling of tools and equipment weighing from 1 to 45 kg. They reported varying degrees of pain and duration of pain in neck, upper and lower back, shoulders, arms, hands, hips and knees.

The group of young workers had a higher VO2-max than the older group: 53±8 vs. 41±6 ml kg-1 min-1. For both groups the work taxed on average 31% of VO2-max and 53% of HR-max. Peak load for a few minutes duration was 54±12% of VO2max and 71±9% of HR-max.

Discussion: For both age groups VO2-max was typical for relatively untrained persons of their age, suggesting that their work did not improve their fitness. During work both groups taxed their aerobic power similarly and equal to the internationally accepted level of a mean of 30 % of max aerobic power during an 8 h working day. These data suggest that elderly workers, when given the possibility, may adjust the physical demands to a level they can sustain. However, individual values suggest that for some unfit senior workers the aerobic demand may exceed the proposed upper limit.

DO PEOPLE ON LONG TERM SICK LEAVE EXPERIENCE AN INCLUDING WORKING LIFE?

BARSNES, B., MAGNUSSEN, L.H., RÅHEIM, M.

SOGN OG FJORDANE UNIVERSITY COLLEGE AND UNIVERSITY OF BERGEN

Introduction: During the last decades, many countries have experienced increasing numbers of people on disability pension and long-term sick leave, despite economic growth and expanding health care systems (Ahlgren and Hammerstrøm, 1999.) In Norway, official reports have investigated the subject to search for explanations and solutions (NOU, 2000). An agreement towards a common responsibility for an including working life has been signed by the Norwegian government and the employee and employers organizations (Arbeids- og velferdsetaten, 2008). The aim of our study is to provide an insight into how people on sick leave experience the cooperation with their employer, their doctor and the governing authorities.

Methods: Focus groups were used for the interviews (Kvale, 1996). The interviews were a part of a larger intervention study at a workplace including 60 employees on long-term (> 6 weeks) sick leave. Twenty-five of the employees were asked to participate in the focus groups. Seventeen responded positively, and were divided into three groups.

Preliminary Results: Most of the participants were satisfied with the way their employer supported them during their period of sick leave, but participants with non-specific disorders (no diagnosis) and participants with a psychiatric diagnosis expressed problems in communicating with their employer.

The views of the doctors' involvement were divided. Some participants expressed very high regards for their doctors, while others complained about them being hard to reach and difficult to communicate with.

The Norwegian Labour and Welfare Services (NAV) mainly received negative reviews, with the participants expressing that they were offered little help. For instance they had to figure out their own rights and remember to fill out the correct forms at the appropriate times on their own.

Discussion: More knowledge is required at the workplaces for employers to better handle employees with non-specific disorders or a psychiatric diagnosis. Social support at the workplace has been shown to be an important factor for job satisfaction, and the opposite might discourage motivation staying in or returning to work (Drabløs, 1993).

For both doctors and officers at NAV a focus on individual communication skills and attitudes should be emphasized (Magnussen et al, 2007). The focus group participants in the present study also suggested that there should be advisers at NAV designated to helping people on sick leave, and that those advisers should be separate from the caseworkers.

RELATION TO CORPORATE HEALTH PROMOTION WHICH AIMS TO PREVENT METABOLIC SYNDROME USING E-WELLNESS SYSTEM

YOSHIZAWA, Y., YOKOYAMA, N., SAKATO, Y., KUNO, S.

UNIVERSITY OF TSUKUBA

[Introduction]This study implemented a health promotion project with a central focus on lifestyle-type exercise programs conducted at convenient times and places to suit the individual lifestyles of the metabolic syndrome research subjects, as well as people at risk, by taking company A, which is expanding nation-wide, as a model. These results will be studied concerning how changes to attitudes in relation to physical activity, as well as the type of effects brought about by work environment thought to affect the volume of physical activity would influence increases in the quantity of physical exercise program activity.

[Method]Six month interventions were carried out on 351 consenting males taken from 4,233 persons that undertook a physical examination, that were aged above 40 years (48.8±8.9 years), and had the company in-house reference value of more than two items as being a metabolic syndrome risk group/applicable group. Intervention results were split into two groups; a group where the average increase per day was less than 3,000 steps (N=170) and a group where the average increase per day was greater than 3,000 steps (N=89).

[Results]With regards to changes in body composition and the number of steps pre and post-intervention, comparing post intervention to pre-intervention, a decrease was seen in body weight, BMI, body fat ratio and physical strength age and an increase was seen in muscle ratio and number of steps. In relation to work environments, including increased number of steps and commuting environment, there was no significant difference in job types and commuting time, but significant differences were seen in whether or not commuting was done by car and whether or not overtime was performed. Further, significant differences were seen in the items where commuting was done by walking, walks were taken, and where exercise was taken during breaks from work. In the greater than 3,000 steps group, commuting was by means of public transport such as buses and trains implied that life was also lived with a high awareness of physical activity. In contrast to this, in the less than 3,000 steps group, the result was that more than 40% commuted by car and a large ratio of respondents stated that overtime was performed.

[Discussion and Conclusions]In the event the standard is taken as an increase of greater than 3000 steps per day, it was evidenced that for the work environments studied, the causal factors of commuting method (non-car usage group) and whether or not overtime was performed were significantly high for the number people who managed to achieve the standard. Further, from the fact that whether commuting is by walking or not has an effect, even on awareness of physical activity, potential was evidenced to deliver certain effects on metabolic syndrome outbreak and its prevention through implementation of exercise programs for the mode of commuting amidst working environments.

BODY COMPOSITION, HANDGRIP STRENGTH AND AEROBIC FITNESS IN 6000 FINNISH MEN

HEISKANEN, J., LÄHDESMÄKI, A., HAKONEN, H., KANKAANPÄÄ, A., KOMULAINEN, J., HAVAS, E.

LIKES FOUNDATION

INTRODUCTION: Obesity is a health threat in Finnish population and there is no wide measured data of Finnish working aged male. Jack the Finn truck tour was executed in September 2007 and May 2008 to increase working aged men's awareness of their health and physical fitness and at the tour was measured over 6000 Finnish men.

METHODS: Body composition (n=6082) was measured by bio electric impedance device InBody 720, which were 3-4 in a truck according to city.

Aerobic fitness (n=3161) was assessed by Polar OwnIndex (VO2max, ml-1*kg-1*min).

Handgrip strength (n=3241) was measured by Saehan hand dynamometer.

Socioeconomic status was researched in three different inquiries (n=1038).

RESULTS: Of all tested men (n=6187) were 55–64 years 27 %, 45–54 yrs 24 %, >64 17 %, 35–44 15 %, <25 6 % and 25–34 11 %. 51 % of the men consisted of workers.

According to BMI slightly or significantly overweight (BMI>25) were <25 years 43% (n=349), 25-34 62% (n=667), 35-44 76 % (n=900), 45-54 79 % (n=1452), 55-64 80 % (n=1686) and >64 79 % (n=1028). Estimated by fat percent (F%) slightly or significantly overweight (F%>20) were <25 years 24%, 25-34 40 %, 35-44 55 %, 45-54 62 %, 55-64 69 % and >64 76 %. The averages of visceral fat area (VFA=cm2) were: <25 years 60, 25-34 86, 35-44 107, 45-54 120, 55-64 133 and >64 143. According to the device manufacturer for individual's health the recommendable value should be under 100 m2 regardless the age.

Skeletal muscle mass (kg) averages were: <25 years 36,7, 25-34 37,6, 35-44 38,3, 45-54 37,3, 55-64 36,0 and >64 33,7. Handgrip strength (kg) had a significant correlation to skeletal muscle mass (kg): 0,60. The correlation of fat mass (kg) was -0,52, F% -0,46, BMI -0,45 and VFA -0,48 to VO2max.

CONCLUSIONS: Obesity is quite common in this kind of population judged by fat percent. Visceral fat tends to increase and skeletal muscle mass decrease according to ageing. Skeletal muscle mass is highly in connection with handgrip strength. Excessive body fat mass reduces aerobic fitness. An average Jack Finn according to this data is approximately 50 years, slightly overweight and abdominal obese, is in fair aerobic shape and has good muscle strength.

This study gives fresh reference value data of working aged male population's physical fitness and health.

AEROBIC FITNESS OF PHYSICAL THERAPY STUDENTS

GJØVAAG, T.

OSLO UNIVERSITY COLLEGE

IntroductionIt is reported that aerobic fitness of Norwegian military recruits from 1985 to 2002 decreased by 8%, while body mass and body mass index increased by 7 and 6% (Dyrstad 2005). It is also reported that the number of military recruits that are dismissed from duty because of poor fitness has increased over the years (Kurtze 2003). Consequently, it is interesting to investigate the aerobic fitness of young male and female students that perform some physical activity as part of their curriculum and examine whether their fitness level have changed in the last decade. MethodsEach year from 2000 to 2009, ~10 % of the physical therapy students enrolled at the Oslo University College were randomly selected to participate in an exercise test. The test was performed on a Monark E834 ergometer. Following warm-up, the work load was increased by 25 W every 60 second until exhaustion. Gas exchange was measured by a SensorMedics 229 metabolic cart. Work rate was recorded in Watts (W). All tests were performed by the same investigator. Results were analysed by ANOVA and independent samples t-test. Statistical significance was set at $p < 0.05$. ResultsMean (SD) age, height, bodyweight and BMI of the 137 persons (67 females and 70 males) in the present study was 23 ±3.9 yrs, 175±9.3 cm, 72 ±12 kg and 23.2 ±2.2. Body weight and BMI did not change during the analysis period.Average (SD) VO2max values over 10 years show significantly higher values for men than for women, i.e. 3.83 ±0.6 vs. 2.67 ± 0.3 L min-1, $p<0.001$.There were no changes in aerobic capacity of neither women nor men during the period from 2000 – 2009. For women and men the average VO2max (SD) values from 2000-2009 were as follows: 2.76±0.2 vs. 3.99±0.5, 2.51±0.29 vs. 4.23±0.29, 2.73±0.49 vs. 4.10±0.36, 2.46±0.27 vs. 3.75±0.41, 2.69±0.36 vs. 3.96±0.66, 2.78±0.27 vs. 3.94±0.56, 2.71±0.28 vs. 3.93±0.43, 2.77±0.15 vs. 3.86±0.63, 2.69±0.43 vs. 3.61±0.68, 2.67±0.43 vs. 3.53±0.75 L min-1. DiscussionThe present findings suggest that the VO2max of young students is unchanged during the last decade. This is in contrast to the findings of Dyrstad (2005). Our population is, however, small (n=137) compared to the study of Dyrstad (loc.cit.), thus our data may not reflect the true aerobic capacity of the general population of young men. In contrast to Dyrstad (2005), body weight and BMI of the men (and women) in the present study was unchanged during the last decade. Hermansen (1965) examined the aerobic capacity of male and female students and observed values of 3.2 and 2.3 L min-1, respectively, which seem comparable to the present findings. This suggests that the aerobic capacity of young male and female students have remained unchanged for the last decades, and that the aerobic capacity of young male physical therapy students is somewhat higher than VO2max of young Norwegian recruits.ReferencesDyrstad SM, Aandstad A, Hallen J (2005). EFFECTS OF THE SLOW SPEED RESISTANCE TRAINING ON ARTERIAL STIFFNESS BY ONE'S OWN WEIGHT.

WOORAM, B., RYOSUKE, T., SHO, O.

KAWASAKI UNIVERSITY OF MEDICAL WELFARE

Properly done resistance training increased strength, muscle mass, bone mineral density, glucose tolerance, functional abilities, and hence potentially reduces morbidity and premature mortality. However, high strength resistance training increased arterial stiffness of a major contributor to cardiovascular disease (1). Okamoto et al. (2006) reported that arterial stiffness was decreased by low-intensity resistance training with slow lifting and lowering for eight weeks (2). However, it did not clarify the effect of slow speed resistance training on arterial stiffness by one's own weight. We hypothesized that slow speed resistance training by one's own weight for eight weeks decreased arterial stiffness.

Subjects were six healthy men (21.2±0.75years old, 169.7±3.93cm, 63.3±5.78kg). Subjects were voluntary participated in this study. Experiments were carried out under the approval of the Ethical Committee of the Kawasaki University of Medical Welfare and all subjects provided written informed consent. Subjects performed slow speed resistance training three times a week for eight weeks. Training was

conducted by two sets of 10 repetitions (3s for eccentric and concentric actions, 1-s pause) of push up, reverse push up, sit up, side arm back extension, half squat, hip lift. Each training items of interval was one minute. It was measured height, weight, body mass index, body fat, brachial blood pressure, ankle blood pressure, brachial-ankle pulse wave velocity (baPWV), pulse pressure, heart rate by four times (before training, four weeks, eight weeks, twelve weeks) for twelve weeks. Subjects rested in the supine position for 10 min before measurements. baPWV was measured using formPWV/ABI (Colin Co., Ltd, Komaki, Japan) and by the oscillometric method. This device recorded the PWV, blood pressure, an electrocardiogram.

There were no significant differences in the before training baPWV among the four groups. Blood pressure, pulse pressure and heart rate were unchanged by slow speed resistance training for eight weeks. %HRmax was 47±4.04 during the slow training.

Consequently, it was clarified that arterial stiffness was not changed by slow speed resistance training of one's own weight for eight weeks.

MEASURING PHYSICAL ACTIVITY IN ACTIVE COMMUTING

SCHANTZ, P., STIGELL, E.

THE RESEARCH UNIT FOR MOVEMENT, HEALTH AND ENVIRONMENT

Purpose

From a public health point of view it is of interest to position different forms of existing physically active behaviours in relation to potential health outcomes. In order to do so, there is a need to establish the energy turnover per week related to a certain form of physical activity. With a research focus on active commuting, it is possible to combine data on route distance, frequency of trips per week and energy demands per kg body weight and km of commuting. For this purpose is has proven to be necessary to develop different methods, and recently we have established a criterion method for route distance measurements (Schantz & Stigell 2009). For reasons of simplicity and large scale studies, the aim of this study is to investigate whether other often used methods for estimating route distances are valid and reproducible.

Methods: A total of 133 individuals participated in the study after having been recruited while walking or cycling to work in the inner urban area of Stockholm, Sweden. They drew their commuting routes on maps and answered different questions in a questionnaire twice, with slightly more than two weeks in between. Route distances were determined with the criterion method (Schantz & Stigell 2009) and compared with distance values obtained by four other methods: self-reported data, straight-line distance, geographic information system (GIS) modelled shortest routes and global positioning system (GPS).

Results: No order effects were noted for any of the methods. All of them, with self-reported data being the sole exception, displayed a very high reproducibility. However, to varying degrees, the methods either under- or overestimated the route distances (range: -21 to +27%).

Conclusion: The study reveals that a number of methods commonly used within the transport sector for determining route distances are not successful in accurately describing route distance when walking or bicycling for commuting purposes. By using correction factors, the deviations in mean values from the corresponding values obtained by the criterion method, can be neutralized. However, on the individual level, deviances from the correct value will still exist. This problem exists for all methods, but it is particularly evident for the self-reported data. Therefore, when there is need for distance values for analytical purposes, for example in a scientific context, the criterion method (Schantz & Stigell 2009) is recommended.

INCREASING PHYSICAL ACTIVITY AND IDENTIFYING REASONS FOR INCATIVITY - A REVIEW

ROVIO, E., LINTUNEN, T., HAVAS, E.

LIKES RESEARCH CENTER, JYVÄSKYLÄ, FINLAND

Introduction: The aim of this poster is to (1) evaluate intervention studies aiming at increasing physical activity and (2) suggest new approaches to the study of physical inactivity and behavioral change from the sociological and social psychological points of view. Most of the people in the developed countries are not sufficiently physically active for physical activity to have a beneficial effects on their health. In addition, physical inactivity decreases productivity in the work place, causes workplace absenteeism and has significant effect on social and health care costs.

Methods: A review of the current literature and earlier physical activity intervention studies.

Results: Researchers have used a wide variety of interventions to stimulate increased physical activity (Biddle & Mutrie, 2008). Informational approaches aim at increasing knowledge and changing attitudes, while behavioral and social approaches aim at teaching behavioral management skills and at creating facilitative social environments. Environmental and policy approaches in turn aim at building a safe and attractive structure for physical activity (e.g., on the institutional/legislative level through changing organizational regulations, policies, and laws). Targets of interventions have been individuals, groups and communities (e.g., school, workplace). In general, it is relatively easy to increase physical activity in the short term, but not permanently (Biddle & Mutrie, 2008). Strategies that would be successful in enhancing physical activity have been hard to determine.

A less studied approach to the investigation of physical activity is to apply tools used in the sciences of sociology and social psychology. Researchers would then be able to focus "hard to reach" segments of the population and identify their complex social and environmental determinants. There is a need to understand the interaction between these inactive individuals and their everyday environment, such as combining work/school and leisure time, shared family time, especially around the (hidden) norms of eating, or evaluating the effect of the information society on physical activity. Inactive individuals in different groups should be identified and the effect of these groups on their physical activity studied. It would be valuable to understand how the role of an inactive person develops.

Conclusions : The challenge of getting people to be physically active is a global one. There is a need for a greater understanding of the determinants of inactivity in people's everyday lives. Long-term studies focusing on inducing change in exercise behavior, explaining what works, how and for whom are missing. Identifying such factors could provide essential guidance for behavioral change.

PERCEPTION OF FATIGUE DURING WATER FITNESS EXERCISE

INVERNIZZI, P., SCURATI, R., LONGO, S., MICHIELON, G.

FACULTY OF ECERCISE SCIENCES - UNIVERSITY OF MILAN

INTRODUCTION: During exercise, subjects can perceive fatigue at different workout intensities. Gender seems to be scarcely related to the perception of fatigue, as well as the age between young and middle-aged people. Borg's RPE (Ratings of Perceived Exertion) and CR10 (Category Ratio anchored at the nr 10) surveys have been designed in order to measure the perception of fatigue [1, 2].

The aim of this study was to analyze the perception of fatigue in middle-aged women during a mid, high and very high intensity water exercise, both in lower (L) and upper (U) body.

METHODS: 11 middle-aged women (44.4±2.9 years, 55.8±4.5 kg, 165±3 cm, BMI 20.5±1.7) participated in the study. Through the Borg's CR10 scale questionnaire, the perception of the fatigue in L and U exercises has been evaluated. During 5 successive training sets, for each body part, CR10 was collected twice (after warm up and after the first block of workout) in order to evaluate two 6-minutes exercises randomly performed, based on standard external charge of workout carried out at three levels: mid (MI), high (HI) and very high (VHI) intensities.

Intensity settings for L exercise (running) were: L-MI = 24 beats at 135 bpm + 8 beats at speed max; L-HI = 16 beats at 135 bpm + 8 beats at speed max; L-VHI = 8 beats at 135 bpm + 8 beats at speed max.

Intensity settings for U exercise (arm ad/abductions) were: U-MI = 6 arm ad/abs at 135 bpm (24 beats) + 8 beats at speed max; U-HI = 4 arm ad/abs at 135 bpm (16 beats) + 8 beats at speed max; U-VHI = 2 arm ad/abs at 135 bpm (8 beats) + 8 beats at speed max.

The effective perception of different intensities during water exercise and the differences between lower and upper body perception have been analyzed.

RESULTS: Subjects were able to properly differentiate exercise intensities, both in lower body and in upper body. Significant differences ($p<.001$) were found.

Comparing L and U, the perception of fatigue differed at MI and VHI (4.95±0.96 vs. 3.85±1.02, $p<.05$ and 7.88±0.60 vs. 6.63±1.28, $p<.05$, respectively) whereas did not differ at HI (6.15±.62 vs. 5.27±1.28, $p>.05$).

CONCLUSION: Middle-aged women are able to differentiate the efforts in water exercise among Mid, High or Very High intensities. However, the intensities proposed were not exactly perceived from our subjects and the efforts were differently perceived in the lower and the upper body exercises. Hence, exercise intensities have to be modified in order to proper manage the efforts and to perform at adequate intensities corresponding to the expected CR10 scores.

METABOLIC RESPONSE DURING AN AQUATREADMILL CLASS IN YOUNG AND MIDDLE AGED ADULTS

PIACENTINI, M.F., CARMINUCCI, R., QUINCI, M.L., GIANFELICI, A., CAPRANICA, L.

UNIVERSITY OF ROME-FORO ITALICO

Introduction: The acute and chronic effects of aquatic exercise for health and fitness has received more and more attention, especially as a mode of exercise for special populations. Aquatreadmill classes are performed in group and conducted by an instructor who with the aid of music regulates exercise intensity on land by showing the velocity per minute (vpm) to reach during each phase of the lesson. Hydrobike has already been shown to be extremely intensive for young participants (Piacentini et al 2007 and 2008, Giacomini et al 2007). Therefore, the purpose of the present study was to evaluate energy cost, heart rate (HR) response and rate of perceived exertion (RPE) during an aquatreadmill lesson in young and older individuals.

Methods: Six young (age: 26.8±4.8 yrs) and 12 middle aged participants (age: 53 + 3.5 yrs) were recruited for the present study. All participants performed the same lesson on an aquatreadmill (HYDRORIDER), that was structured in 9 different phases characterized by different vpms each five minutes long. Ventilatory gases were collected (FITMATE, COSMED, Italy) and HR monitored (Polar, Finland) during exercise and RPE was measured at the end of each phase. A non parametric Friedman test was performed for significance ($p<0.05$).

Results: As expected, there was a difference in VO2, RPE and HR between the different phases of the lesson. Exercise intensity was significantly ($p<0.05$) different between young and older adults. The average intensity measured as %HRmax was 61+5% for the young and 70+5% for the middle aged while %VO2max did not differ between groups (56+14% and 57+13% for young and middle aged respectively). The average RPE measured during the classes was 10.6+0.8 and 10+2.5 for young and middle aged respectively.

Discussion/Conclusions

For the young group, this activity does not represent an intensive training. According to ACSM guidelines, they reach an intensity classified as moderate, both for HR and RPE. Therefore, to increase cardiovascular fitness other types of activities are suggested for young individuals (ACSM 1998). Instead, the group of middle aged participants, showed higher HR but moderate perception of effort. These results are in contrast with previous work (Raffaelli et al 2007), that found that at the same relative intensity, the perception of effort is lower in land based compared to water based activities. According to our results, the RPE alone could be misleading in programming exercise for

individuals above 50 years of age, in an aquatic environment, because despite low RPE values, the HR increased throughout the whole lesson.

EFFECTS OF WATER EXERCISE DVD MEDIA AIMNG EXERCISE ADHERENCE FOR ELDERLY FROM COLD SNOWY REGION

HANAI, A., HANAI, Y., KANEDA, K.

HOKUSHO UNIVERSITY

Introduction: We have long been studying about the benefits of water exercise for elderly in cold snowy region (CSR). It is important to keep physical fitness to prevent slips and falls in these people (Hanai et al, 2006), especially during winter season when their physical activity fall due to snowy climate. In the present study, to facilitate the beneficial effects and their adherence of water exercise program, we developed a self-training protocol of water exercise that could be performed in swimming pool and also at Japanese bathtub. This protocol was recorded visually in DVD media, and distributed to participants who continued, or discontinued the water exercise class during winter season (Oct to Feb 2008). The purpose of the present study was to investigate the effects of self-training protocol prescription for elderly in CSR on physical fitness levels and exercise adherence.

Methods: Twelve subjects were participated water exercise class from May to November 2008. Prior to winter season, (September) we distributed a water exercise protocol by DVD media to facilitate exercise adherence during winter season. From December 2008 to March 2009, half of the subjects continued WE class (CWE group), and the other half discontinued (DWE group). The state of exercise adherence was asked by the questionnaire. Also, Life-related fitness assessment(LRFA) for the people in Northern regions included side jump, sit ups and step over and duck under the rope (Watanabe et al. 2008) were tested in the periods at May, October 2008 and March 2009. Analyzed data were compared between the groups.

Results: Life-related fitness tended to improve or maintain at most of the subjects during the periods from May to November 2008. However, the data of LRFA showed significant decline at DWE group in the periods from November 2008 to March 2009. Also, the state of exercise adherence was low at DWE group.

Discussion: The contents of water exercise DVD media was developed including lower limbs strengthening, balance and stretching training at swimming pool, also exercise at Japanese bathtub as home-based exercise. Both groups applied self-training prescription by DVD media, however, high percentage of exercise adherence and improvement of LRFA were found only at CWE group. DVD media was useful tool to raise exercise adherence with participation of group-based exercise class.

THE IMPACT OF A 6 MONTH JEET KUNE DO TRAINING PROGRAMME ON PHYSICAL FITNESS IN UNTRAINED MALES

MICHIELON, G., INVERNIZZI, P.L., SCURATI, R., LONGO, S.

FACULTY OF ECERCISE SCIENCES - UNIVERSITY OF MILAN

INTRODUCTION: Recently the relationship between martial arts and physical fitness (1) has been pointed out, specially in the elderly (2). Along with other martial arts Jeet Kune Do is a complete activity in terms of physical demand, such as strength and flexibility. The aim of this study was to evaluate the physical fitness impact due to a 6 months training programme based on Jeet Kune Do martial art in untrained people.

METHODS: Ten untrained males (M, mean±SD, age 26.3±5.6 years, height 174±0.1 cm, body mass 71.1±8.4 kg) volunteered for this study. None of them had previous experiences in martial arts. After familiarisation with all the tests, each participant underwent a series of physical fitness evaluations: upper limbs rapidity (UR) measured by the time (s) of 20 consecutively arm extensions, back and hamstrings flexibility (BF) measured by the distance of the reached point (cm) after a trunk flexion, hip flexibility (HF) measured by the degree (deg) of maximum legs width on the transverse plane in the sitting position, reaction time (RT) measured by the seconds (s) employed to punch an aim after a sound signal, lower limbs power (LP) measured by the distance (m) reached after a long jump, punch attack endurance (PE) measured by heart rate (HR, bpm) after two series of punch combinations. These tests were repeated after six months of a specific Jeet Kune Do training programme. The programme was divided as follows: endurance (months 1-2: 400 min, months 3-4: 320 min, months 5-6: 240 min), submaximal strength (months 1-2: 240 min, months 3-4: 320 min, months 5-6: 320 min), maximal strength (months 1-2: 320 min, months 3-4: 240 min, months 5-6: 240 min), rapidity (months 1-2: 240 min, months 3-4: 320 min, months 5-6: 480 min) and relaxation and flexibility (months 1-2: 240 min, months 3-4: 240 min, months 5-6: 160 min).

RESULTS: Between pre and post training, improvements expressed as absolute percentage were statistically significant ($p<0.05$) in UR (13%), BF (90%), HF (1%), RT (23%), LP (2%) and PE (9%).

CONCLUSIONS: Observing the pre- and post- percentage improvements in all the tests, Jeet Kune Do appeared to be effective in enhancing physical fitness level of untrained males, specially regarding UR, BF and RT. A lack of a control group makes arguable whether small increases (i.e. HF, LP and PE) would be detectable after this kind of training programme. Nevertheless the relationship between martial arts and physical fitness seems to be strong concerning trunk flexibility, reaction time and upper limbs rapidity, therefore we suggest that further studies should better elucidate the impact of Jeet Kune Do on physical fitness.

STUDY CONCERNING THE TRACK AND FIELD ROLE IN EDUCATION FOR HEALTH

MIHAILESCU, L., MIHAILESCU, N.

UNIVERSITY OF PITESTI

Introduction. Recent researches are emphasizing that in the European Union, until 27% of men and 38 % of the women are obsesses. The same information sources are underlining that the number of the overweight children is growing every year with approximately 400 000 and they estimate that, 10 to 30% of the children between 7–11 years and 8 to 25 % of the teenagers, 14–17 years are overweight.

Hypothesis. We consider that, by the multiple effects of the running, in association with a proper food diet, it can be reestablished the morpho-functional and psycho-affective balance of the people, and implicit regaining the ponderal homeostasis. The effects of the walking and running therapy and the combinations between them are obvious in time at the circulator, respirator, digestive and locomotory apparatus level as well as the neuron-endocrine-metabolic level.

Content.Subjects and research methods. The research was focused on an experiment realized from 2006 to 2008, on a sample of 200 pupils between 16–18 years, pupils that were practicing athletics during extracurricular lessons, in urban environment.

During the experiment, by determination of the basic metabolism(%), we discovered that: running in 200m/minute rhythm, in the summer, on flat, plain ground – 445%; running in 200m/minute rhythm, in the winter, on to the mountain - 1.300%; running in 400m/minute rhythm, in the summer, on flat, plain ground - 8.000%; running in 400m/minute rhythm, in the winter, on to the mountain - 10.000%.

Conclusions. The track and field skills have many trumps that recommend it's in order to be used in prophylactic and therapeutic purpose: The track and field skills have in their structure basic motive skills, they have a natural prevalent character, they are easy to practice: march, running, jump, throw; The track and field skills can be practiced in natural or improvised conditions, without being necessary a sophisticated and expensive material base; The specific effort of the middle-distance, long-distance and very long-distance, determines a big energetic consumption, the specific effort of this kind of running being an anaerobic one that encourages the acceleration of the "burns", the metabolic catabolism, until the decomposition of the lipids;

BODY FAT DISTRIBUTION AND HEALTH-RELATED QUALITY OF LIFE

THEODOROPOULOU, E., KARTEROLIOTIS, K.

UNIVERSITY OF ATHENS

Background: Obesity is a risk factor for diseases and adversely affects Health-Related Quality of Life (HRQoL), which has been defined as an individual's perceived physical and mental health over time (1). However, the effects of obesity in HRQoL in the Greek population have not been previously examined. The aim of the present study was to investigate the impact of obesity on HRQoL in a Greek adult population.

Methods: Participants were 327 men and women between the ages of 30 and 50 years. The waist to hip ratio (WHR) was calculated from measures of waist and hip circumferences, whereas the body fat (BF) was estimated from biceps, triceps, suprailiac and abdominal skinfolds. Participants were categorized to four WHR groups and to three BF groups. The Greek version of SF-36 (3) was used for the evaluation of the HRQoL and the Baecke physical activity (PA) questionnaire (4) for the assessment of two PA indices (leisure time and sport). A series of MANCOVAs were conducted to examine the differences in HRQoL between the WHR groups and the BF groups.

Results: Significant differences were found between the WHR groups with the sex (Wilks' lambda=0,870, p=0.049) and the sport index (Wilks' lambda=0,725, p=0.000) as covariates. Participants with low WHR have higher values in physical functioning subscale (F(3, 323)= 37.784, p=0.000) and in physical health factor (F(3, 323)= 9.590, p=0.000) than participants with high and very high WHR. As far as the results of BF groups were concerned, significant differences were found with the sex (Wilks' lambda=0,868, p=0.001) and the sport index (Wilks' lambda=0,650, p=0.000) as covariates. Participants with normal BF had higher values in physical functioning subscale (F(2, 324)= 77.870, p=0.000) and in physical health factor (F(2, 324)= 26.846, p=0.000) than overweight and obese, whereas overweight had higher values in the same subscales than obese. However, participants with normal BF and overweight had lower values in psychological health factor (F(2, 324)= 10.135, p=0.000) than obese. Also, overweight had lower values in social functioning (F(2, 324)= 3.295, p=0.038) and mental health (F(2, 324)= 3.625, p=0.028) subscales than obese.

Conclusions: The results confirm the negative impact of total and central adiposity on the physical functioning and health in the Greek adult population.

BODY MASS INDEX AND HEALTH-RELATED QUALITY OF LIFE AMONG GREEK ADULTS

THEODOROPOULOU, E., TSAMITA, I., KARTEROLIOTIS, K.

UNIVERSITY OF ATHENS

Background: The prevalence of obesity is increasing and contributes to the burden of diseases. A few studies in various countries have indicated that obesity adversely affects Health-Related Quality of Life (HRQoL) and mainly physical health (1-2). HRQoL has been defined as

an individual's perceived physical and mental health over time. However, the effects of obesity in HRQoL in the Greek population have not been previously examined. The aim of the present study was to investigate the impact of obesity on HRQoL in a Greek adult population.

Methods: Participants were 327 healthy men and women between the ages of 30 and 50 years. Body weight was measured to the nearest 100 gr with calibrated scales, height in bare feet to the nearest cm. Body Mass Index (BMI) was calculated as weight (kg) divided by height (m) squared. Participants were categorized to three BMI groups (normal weight, overweight, obese). The Greek version of SF-36 was used for the evaluation of the HRQoL, which includes 8 subscales each measuring a separate health factor (3). Two indices of physical activity (PA) were assessed (leisure time and sport) using the Baecke PA questionnaire (4). A series of MANCOVAs were conducted to examine the differences in HRQoL between the three BMI groups, whereas age, sex and the two PA indices were the covariates.

Results: Significant differences were found with the sex (Wilks' lambda=0.814, F(2, 324)= 3.378, p=0.000), the sport index (Wilks' lambda=0.551, F(2, 324)= 10.817, p=0.000) and the leisure time index (Wilks' lambda=0.839, F(2, 324)= 2.857, p=0.000) as covariates. Participants with normal weight had higher values in physical functioning subscale (F(2, 324)= 115.986, p=0.000) and in physical health factor (F(2, 324)= 25.342, p=0.000) than overweight and obese, whereas overweight had higher values in the same subscales than obese. However, participants with normal weight had lower values in psychological health factor (F(2, 324)= 6.552, p=0.002) than obese.

Conclusions: The results confirm the negative impact of obesity on the physical functioning and health in the Greek adult population.

PHYSICAL ACTIVITY LEVELS OF TOTAL JOINT ARTHROPLASTY PATIENTS: A DESCRIPTIVE META-ANALYSIS

IMPELLIZZERI, F.M., NAAL, F.D.

SCHULTHESS KLINIK

INTRODUCTION. Physical inactivity is a modifiable lifestyle-related risk factor considered one of the leading causes for the major non-communicable chronic diseases. The proportion of individuals meeting the health-enhancing physical activity (PA) recommended levels decreases with increasing age. This appears even more evident in patients with osteoarthritis of the hip or knee. Total joint arthroplasty (TJA) is a well established successful surgical procedure for patients suffering from severe osteoarthritis and joint degeneration. Therefore, a successful treatment such as TJA should not only improve pain and function, but also allow patients to be physically active. The determination of the current state of PA research in TJA patients regarding quality and quantity represents the cornerstone for future investigations. The aim of this study was to systematically review the literature on PA levels in TJA patients.

METHODS. Relevant publications were identified using computer-aided search (MEDLINE, Cochrane Library, and EMBASE). Of 1688 identified citations, 1631 articles were excluded after screening titles and abstracts. The fulltexts of the remaining 57 articles were retrieved and analyzed. Twenty-seven articles met the inclusion criteria. Where possible, data were summarized using meta-analytic methods (random-effect models for taking into account any heterogeneity).

RESULTS. PA has been quantified using self-reported questionnaires, pedometers and accelerometers. Meta-analysis was only possible for the studies were PA was measured using pedometers (n=15) and accelerometers (n=6). The wMean measured using accelerometers was 11250 (95%CI: 10290 to 12210) steps/day, and was higher than steps measured using pedometers [5022 (4305 to 5740) steps/day]. Subgroup analysis on pedometer data only showed higher PA in patients assessed <5 yrs from the surgery [4251 (3427 to 5074) steps/day] than >5 yrs [6032 (5369 to 6695) steps/day]. Meta-regression (steps vs age) showed that 1 year of aging would correspond to a PA decrease of 90 steps/day (-156 to -22; P=0.008).

DISCUSSION. The results of this study showed that PA levels in TJA patients as assessed by pedometers are well below the currently recommended level of 10000 steps/day. Furthermore, PA levels decreased with increasing age. Patients >65 years old performed less steps than similar aged healthy people [4613 (3457-5770) vs 6565 (4897-8233) steps/day, respectively] as reported in a recent meta-analysis (Bohannon, 2007). Similar findings were found examining qualitatively PA obtained from self reports. A difference superior to that reported in the literature was found between PA assessed using accelerometers vs pedometers. In conclusion, this study showed that PA levels of TJA patients are lower than those of healthy people and below recommended levels. These observations highlight the urgent need for strategies to increase PA levels in this population.

MOTIVATION FOR LIFE STYLE CHANGES TO IMPROVE HEALTH IN PEOPLE WITH IMPAIRED GLUCOSE TOLERANCE

HANSEN, E., LANDSTAD, B.J., HELLZÉN, O., GUNDERSEN, K.T., SVEBAK, S.

NORD-TRØNDELAG UNIVERSITY COLLEGE

Introduction: The association of an inactive lifestyle with obesity and Type 2 diabetes is well known (Ackermann et al., 2008; Schneider & Elouzi, 2000). Correspondingly, research over the last decades has provided strong support for the positive effect of physical activity in the treatment and obviation of Type 2 diabetes (Califf et al., 2008; Krook et al., 2003). The aim of the study was to elucidate attitudes and

concerns about motivation to adopt a new lifestyle with physical activity and other health promoting elements to reduce impaired glucose tolerance (IGT) and, consequently, the risk of having Type 2 diabetes.

Methods: Eighteen subjects in central Norway participated in a semi structured interview study, defined as participants with IGT according to guidelines by WHO (1999). The sample consisted of 4 men and 14 women divided into two groups with 9 individuals in each. Both Group 1 and Group 2 included two men and seven women. Group 1 was enrolled in a physical exercise program from start of the project, whereas Group 2 was put on hold until Group 1 had completed their instructed training program. The participants were between 33 and 69 years old. This interview study is part of a larger research project.

Results: The participants attributed great significance to their physical health and were strongly motivated to prevent disease development. This focus changed their priorities regarding daily living in certain ways, and related issues were frequently addressed in the semi-structured interviews. Manifest analysis of the content across all interviews justified the identification of four important categories of content: Structure and rhythm, Sickness, Activity and Social relations.

Discussion: The participants in the project increased their awareness of the importance of structure in everyday life, including rhythm of meals and regular exercise to avoid developing Type 2 diabetes. These findings are in line with those of a review study by Yates et al., (2007), which indicates the contribution of physical activity may be of importance, but independent of dietary changes and weight loss, in the prevention of Type 2 diabetes in people with symptoms of pre-diabetes is equivocal.

UNSTABLE VS. CONVENTIONAL JOGGING SHOE CONSTRUCTION: DIFFERENCES IN PHYSIOLOGICAL DEMAND AT LOW-INTENSE RUNNING?

RING-DIMITRIOU, S., STÖGGL, T., HEHENBERGER, E., MÜLLER, E.

UNIVERSITY OF SALZBURG

Introduction: It has been demonstrated that the construction of footwear mimicking a barefoot condition can affect knee pain and joint loading (Nigg et al., 2006; Shakoor et al., 2008). Furthermore differences in energy requirement depending on the type of soles were reported in intensive running (Nigg et al., 2003) and prolonged walking (Saito et al., 2007). However, the impact of an unstable shoe construction on the physiological demand was not measured yet and was the subject of that investigation.

Methods: Twenty eight adults aged 24.1±2.8 yrs (67±8.1 kg, 22±1.7 kg/m) participated in 3 tests. An incremental step-test until exhaustion was conducted on a motorized treadmill (1% inclination, 5 min steps, 30 s rest, 0.5 m/s increment, Saturn 4.0, hp/cosmos, GE) to determine running velocity at 2 mmol/l blood lactate concentration (v-2LA; arterialized earlobe blood; lactate analyzer Biosen 5040, EKF Diagnostics, GE). After 2 wks four 30 min lasting sub-maximal tests at v-2LA with the conventional jogging shoe of the individual (CS) or the unstable Masai Boot Technology® shoe (US) were completed in the sequence CS-US on first day and US-CS on second day separated by 48 hrs from each other (1h rest in between daily bouts). Each 30min-test was split in 10min bouts with a 30s rest period in between to sample arterialized blood for determination of LA. During the whole test oxygen uptake (VO2) and energy expenditure (kcal) were measured with a respiratory gas exchange analyzer (K4b², Cosmed, IT). Heart rate (HR) was monitored via beat-to-beat transmitter (Polar, FI). Before completing the submaximal tests subjects got a standardized instruction into running with the US over 2 wks. The mean values of the two measures in each situation were used as criterion variables. The hypothesis was tested with a paired sample t-test at p-level of <0.05. Cohens' d was determined for effect size.

Results: The physiological response while running with US at v-2LA increased significantly by 23% in LA ($t(27)=-5.6$, $p=.0001$, $d=1.1$), 7% in kcal ($t(27)=-4.3$, $p=.0001$, $d=0.7$), 4% in VO2 ($t(27)=-2.4$, $p=.02$, $d=0.4$) and 2% in HR ($t(27)=-3.2$, $p=.003$, $d=0.6$) compared to CS.

Conclusion

As indicated by the medium to large effect size (d) low-intensive running over 30 min with the unstable shoes enhanced the physiological load compared to the CS significantly. We assume that the larger involvement of lower-extremity small muscle groups was responsible for the response as demonstrated by studies on instable shoe construction (Nigg et al., 2006).

PHYSICAL EFFICIENCY AND TRAINING SUITABILITY OF HEALTH RESTRICTED CONSCRIPTS ON EXAMPLE OF UNIT IN ESTONIAN ARMY

ANTSON, H., MÄRKS, H.

ESTONIAN DEFENCE FORCE, UNIVERSITY OF TALLINN

Introduction: Estonian draftees are divided into 4 category based on their health condition – healthy, healthy with restrictions, unfit temporary and unfit steadily. Only draftees from first and second category are allowed for entering into service . All soldiers in Estonian Defence Forces must take the Army Physical Fitness Test (APFT) in four stages (first in the beginning, second at the end of the basic training

course,third in the middle and fourth at the end of the service) during the service. Current follow-up study continues recent investigations among conscripts having revealed relations between their physical performance and health problems.

Methods: 1312 male conscripts, aged 18-22 participated in the survey in years 2007-2008. The individual medical records of freshmen as well as their APFT results were collected, stored in a data base and analysed.

Results: The division of received conscripts in years 2007-2008 is following: 76% healthy and 24 % healthy with restrictions . In spite of that, 9-15 % from conscripts were excluded from service before the end of conscript time (in years 2006-2008). When exploring the dynamics of physical progress on conscripts serving in Estonian Military, most recent studies have been indicated, that the soldiers within category healthy did not deviate significantly from normal average physical test development dynamics of the last five years (r=0,87, p<0,05). Simultaneously the physical test development dynamics of the soldiers˙group healthy with restrictions has weakly correlated with the average physical test development dynamics of the latest five years (r=0,18, p< 0,005).

Discussion: M-type (musculosceletal) diseases (49 % from all within category healthy with restrictions) expressed less decreasing effects to the soldiers´fitness dynamics than any type of diseases. Most of soldiers, who did not pass any stages of APFT belonged to the F- (16 %), I- (5 %), Q- (5%) and H-type (5%) group of diseases (F-mental disorders, I- diseases of circulatory system, Q- congenital malformations, H-diseases of the eye). The soldiers from latter groups didn´t acquire necessary fitness rate by the end of service time and a lot of them didn´t hold out (they were excluded to reserve before the end). Consequently , physical efficiency and training suitability of the health restricted conscripts is quite low (excluding M-type diseases).Thereby, there is an indirect evidence that economical cost for livelihood of conscripts within the category healthy with restrictions for groups of F-, I-, Q- and H-type diseases can be considerable.

EFFECTS OF EXERCISE ON PHYSICAL FITNESS FACTORS, BODY COMPOSITION AND BLOOD LIPIDS OF ADDICTED PERSONS AFTER ONE YEAR QUITTING DRUGS

BANITALEBI, E., FARAMARZI, M., MARANDI, M., AZAMIAN-JAZI, A.

ISLAMIC AZAD UNIVERSITY, SHAHREKORD BRANCH

Effects of exercise on physical fitness factors, body composition and blood lipids of addicted persons after one year quitting drugs

1-Ebrahim Banitalebi (M.Sc) Islamic Azad University of Shahrekord Branch. 2-Mohammad Faramarzi (Ph.d) Shahrekord University. 3-Mohammad Marandi (Ph.d) Isfahan University. 4-Akbar Azamian-Jazi (Ph.d) Shahrekord University .

Introduction: There is some concern that drugs abuse treatment may actually pose a risk toward unhealthy eating and weight gain. Dysfunctional eating patterns and excessive weight gains have been observed during recovery from drug and alcohol addictions (Cowan and Devine 2008). The purpose of this study was to determine amount of weight gain, Lipids, WHR, BMI, fat percentage some physical fitness factors after quitting drugs. In addition, the study of the efficacy of a selected physical activity on some anthropometric variables (weight, BMI, and WHR), blood lipids, and physical fitness factors such (Vo2max, flexibility, and fat percentage) on subjects who have quitted abusing drugs between 30-60 days.

Method: 37 subjects who were 23-49 years old, and had one-year quitting history. Participants were randomized at approximately 1:1 ratio under the supervision of a project investigator (exercise group 18 persons and control group 19 persons), and 38 individuals completed the entire study; 16 persons were in exercise group and 15 persons were in control group. Exercise consisted primarily of some plays such as badminton playing, walking and so on. Exercise duration progressed from 20 minutes at the baseline to 45 minutes at the end of 12 weeks, and Intensity of exercise progressed from 50% of heart rate reserve of baseline to 70 % at 12 weeks. Body composition was assessed using the sum of three skin-fold measurement specific for males (chest, abdomen, and tight) (ACSM 2000). Total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C) and triglyceride (TG) were measured enzymatically using Diagnostic kits.

Results: There were significant decrease in weight(p=0.002), BMI(P=0.001), WHR(P=0.004), Ch(P=0.009), HDL(0.045) and LDL(0.002), Vo2max(p=0.000), flexibility(P=0.000) and Pull-up(P=0.001), but There were not in VLDL(P=0.9) and TG(P=0.544).

Conclusion: One of the reasons for weight gain is because nicotine and drugs speed up body metabolism (Cowan and Devine 2008). It postulates that for these measurements, increasing is inevitable (Abrantes 2006). Exercise without changes in diet produced significant reduction in weight gain, and increasing BMI (p<0.01). It appears that, physical activity and exercise can prevent or manage overweight after quitting drugs, substances and smoking.

HYDRODENSITOMETRY

MALÁ, L., ZAHÁLKA, F., MALÝ, T.

FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY PRAGUE

Problem

The actual problem of body composition (BC) evoked the formulation of five models of BC and development of evaluating methods. Currently used methods are principally based on measured values of indicators (body density, total body water), which are later on converted into parameters identifying BC. The results of methods correlate together, but the methods do not show identical results. Coming out from multi-componential methods of assessment of BC, hydrodensitometry is one of reference methods (Kennon T. Francis, 1990).

Methods: In hydrodensitometry we use a water tank (90x110x145 cm) above which there is a weighing chair assembly and mobile scales with an accuracy of 0.001kg. The measured person is weighed on land at first, than under water after maximal expiration. Before the measurement the weight of device calibrated so that recording of net weight is enabled. The scales communicate with a PC which records the weight during a constant time period. By means of specific prediction formulas coming out from the assumption of constant density and hydration of fat and fat free mass it deduces amount of fat mass and lean body mass in an organism. A residual volume is regarded by a constant.

Results: The result of underwater weighing is 10 values of weights under water, of body densities and of fat percentage according to various prediction formulas in every tested person (Brozek et al., 1963; Siri, 1961). On one expiration we record one to two values of the weight under water; the resultant value is, concerning scales oscillation, an average value within 2 s. Applied measurements show that after examinee's experience it is possible to record even 7 almost equal measurements (in various examinees: 4.89±0.05 kg, 4.40±0.10 kg, 3.81±0.01 kg, 3.95±0.02 kg). For a definitive evaluation it is possible to take the average of three records or the higher weight with the lowest part of fat tissue.

Limitations

Limitations of hydrodensitometry consist of an individual fluctuation of hydration of fat free mass and of density of particular components related to age, sex and amount of fat mass. The maximal expiration of the examine and the chosen method of residual volume estimation are also one of the limitations. Assuming minimisation of possible errors sources we may find hydrodensitometry as one of the most suitable laboratory methods for BC assessment.

VALIDITY AND RELIABILITY OF SHORT-FORM INTERNATIONAL PHYSICAL ACTIVITY QUESTIONNAIRE IN SEDENTARY COLLAGE STUDENTS: PHYSIOLOGICAL AND CLINICAL RELEVANT.

ALOMARI, M., QHATAN, R., KEEWAN, E., ABUWARDEH, A., AMER, A., KHABOUR, O.

JORDAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: The international physical activity questionnaire (IPAQ) is a simple widespread tool to assess physical activity (PA) pattern in a variety of populations and societies. However, the validity against fitness and circulatory measures and the reliability of the short-form version in Middle Eastern sedentary collage students has not been examined.

METHODOLOGY: Therefore, the IPAQ was administered 3 times in 127 sedentary collage students with age range 18-23 years. Subsequently, percent body fat (%BF), body mass index (BMI), waist/hip (W/H) ratio, maximum walking distance achieved in 6 minutes (6MWD), and maximum handgrip strength (MHG) were examined. Blood pressure (BP) was measured using standard auscultatory method. The questionnaire reliability and validity were performed using intraclass (ICC) and Pearson correlations, respectively, whereas the Student t-tests was used to compare the IAPQ items between males and females.

RESULTS: The ICC coefficients for walking, moderate, vigorous and total PA/week were, 0.97, 0.96, 0.97 and 0.97, respectively. Additionally, males as compared with females scored greater in walking (549.3±684.5 vs. 163.5±340.6; p=0.001) and less in moderate (540.0±711.5 vs. 1426.1±2005.1; p=0.006) PAs, while vigorous (4757.3±4583.5 vs. 3565.5±2391.2; p=0.11) and total (5950.7±5028.8 vs. 5132.9±3762.8; p=0.35) PAs were the same. Additionally walking PA correlated with muscle mass (r=0.5; p=0.0001), BMI (r=0.2; p=0.01), W/H ratio (r=0.3; p=0.002), MHG (r=0.3; p=0.004), and 6MWD (r=0.2; p=0.03) as well as with diastolic (r=-0.6; p=0.004), mean (r=-0.5; p=0.05) and pulse pressure (r=0.5; p=0.01). Moderate PA correlated with body mass index (r=-0.2; p=0.04) and W/H ratio (r=-0.3; p=0.007). Finally vigorous PA correlated with 6MWD (r=0.2; p=0.04) and total PA correlated with %BF (r=-0.3; p=0.008) and BMI (r=-0.2; p=0.05).

CONCLUSION:

The results indicate that IPAQ items are reliable with the walking and moderate PA items can discriminate between males and females. Additionally, validity of the questionnaire items against health-related fitness and BP measures is acceptable, with the walking appears to be most representative when assessing PA pattern in sedentary collage students. Finally, the association of walking PA with blood pressure measures is particularly important because of its physiological and clinical relevant.

EFFECTS OF A CUSTOM-MADE MOUTH GUARD ON THE MUSCLE STRENGTH AND POWER

SUGAWARA, M.

NAGASAKI UNIVERSITY, FACULTY OF EDUCATION

The use of the mouth guard is essential in contact sports for mitigating the impact on the head and protecting the mouth, its surrounding tissues, and head and neck from injuries. Recently, mouth guards have come to be used not only to prevent injuries and protect the teeth, but also to improve athletic performance. In this study, effects of custom-made mouth guards prepared by a dentist on dentition models that closely fit the wearers, and are comfortable to wear on the muscle strength and power of athletes were evaluated in 11 college American football players. The leg-flexion strength, leg-stretch strength, arm-flexion strength, grip strength, back strength, vertical jump, standing trunk flexion, jumping reaction time, anaerobic power, and blood lactate level were measured with and without using the mouth guard. The leg-flexion strength and leg-stretch strength were increased significantly by the use of the mouth guard. The arm-flexion strength, grip strength, back strength, vertical jump, and standing trunk flexion were improved, though not significantly, by the use of the mouth guard. No significant difference was observed in the jumping reaction time between with and without the mouth guard. The anaerobic power was significantly greater ($p<0.05$) with the mouth guard (992.64±81.95 Watt) than without the mouth guard (912.45±84.59 Watt). No significant difference was observed in the increase in the blood lactate level after the measurement of the anaerobic power between with and without the mouth guard, probably because the subjects could exert muscle strength more efficiently by the use of the mouth guard. The results of this study suggest that the use of a custom-made mouth guard is advantageous for exertion of muscle strength and power. Whether the mouth guard is effective for the prevention of dental injuries in actual sports activities is another important question to be addressed in future studies.

STUDY OF THE CARDIOVASCULAR RESPONSE TO HARVARD STEP TEST IN DRUG ADDICTS IN REHABILITATION PHASE

SAAVEDRA, F., MARTINS, R., SANTOS, A., RIBEIRO, R.

UNIVERSITY OF TRÁS-OS-MONTES

This case-control study intended to evaluate the physiological response to effort (cardiovascular component) on a group of drug abusers in therapy, and elucidate eventual insufficiencies in cardiovascular performance as compared to a control group.

Our sample was constituted by twelve adult men drug consumers (28 +4.59 years of age; 75.38 +6.57 Kg weight and 179 +0.08 cm height) included in a rehabilitation program (mean of 6.04 +5.79 months of participation in the program), and 14 controls (25.07 +5.30 years of age; 75.25 +10.76 Kg weight and 175.5 +0.07 cm height) took part on this investigation. All the subjects were healthy and had no participation on any organized physical activity. We used the Harvard Step Test to evaluate the recovery index, recording the heart rate every 5 seconds with a polar monitor.

Results show no significant differences ($p>0.05$) in recovery indexes between both groups (69.34 +14.28 experimental group and 67.40 +5.58 the control group), as well as no differences was observed in beats per minute at every minutes of the test and in the percent of variation of heart rate in all 60 seconds. When we excluded from the statistical analysis, the drug abusers that consumed cocaine (n=3), no changes in the relations were noted. The means comparison (T-student) between cocaine consumers and control group didn't result on differences in any dependent variable. After mean adjustment with ANOVA, the results suggest some effect of weight and age in test performance, or else, this variables account for the variations in results between subjects.

We conclude that cardiovascular capacity, measured has the response to a sub-maximal test is not impaired in drug abusers. Conversely, individuals in therapy for drug abuse should be encouraged to participate in sports activities, representing sub-maximal efforts. We need more evidence to support our results, namely other tests and functional evaluations, and knowing the cardiovascular response to maximal effort.

There is scarce evidence in Spain about effective ways of producing sustained increases in patients' physical activity (PA) that can be easily integrated into the primary care work routine.

PURPOSE. To evaluate the short and mid-term impact of a PA program over a patients' total PA and their attitude towards practicing PA, using a pilot randomized control trial (RCT).

METHODS. Following ethical approval, thirty primary care patients with a low level of PA, an associated chronic disease and non medical contraindication to practice PA (5 male, 25 female; 69±10 years; 31.3±2.9 kg/m2) were randomly allocated to a control group (CG)(n=12) (usual care) or intervention group (IG) (n=18) (3-month PA program; two sessions/week; 60 minutes/session). Previously validated questionnaires to measure total PA (IPAQ short version) and Stages of Change (SOC) for PA were administered 4 times: pre, post intervention, 3 and 6-month follow-up. Effects over the intervention were evaluated by calculating the magnitude of change between pre and 3 and 6-month follow-up scores for total METS minutes/week and maintaining/changing patient's SOC for PA. Independent t-test (METS minutes/week) and Chi-square test (SOC for PA) were used to identify significant differences and associations between groups.

RESULTS. Patients' adherence to the program was high (78% assistance). The average METS minutes/week at baseline were 1662 (±1362) for the CG and 1659 (±1235) for IG. The IG showed higher MET minutes/week in the 3-month follow-up (2823±1813) and 6-month follow-up (1992±1201) than the CG (1731±1281 in the 3-month follow up and 1707±1249 in the 6-month follow up). The difference between groups was significant ($t(18)=-3.12$, $p=0.006$). At baseline, 66% of the IG (8 subjects) and 80% of the CG (8 subjects) were at the precontemplation/contemplation stage for PA. In the follow-up, 95%

of the IG (14 subjects) had moved towards the action/maintenance stages while 100% of the CG (12 subjects) remained in the initial SOC. There was a significant association between participating in the PA program and patients' changing their SOC for PA (Χ2(3)=24.7, $p<0.001$).

CONCLUSION. This preliminary data indicated the effectiveness of a low-cost PA promotion program on patients' short and mid term adherence to PA. Further research will evaluate the long-term adherence (12-month) of the program on a RCT with more than 400 patients.

PREDICTING MAXIMAL OXYGEN UPTAKE FROM A PERCEPTUALLY REGULATED EXERCISE TEST <PRET>.

MORRIS, M., LAMB, K.L., BUCKLEY, J., COTTERRELL, D.

UNIVERSITY OF CHESTER

Introduction: Recent investigations (Eston et al, 2005; 2008; Morris et al, 2009, in press) have provided encouraging evidence to support the prediction of maximal oxygen uptake (Vo2max) from a perceptually regulated exercise test (PRET). The PRET has typically required participants to exert themselves over a range of intensities up to a rating of perceived exertion (RPE) of 17 (Very hard) on Borg's 6-20 scale. This intensity is, however, considered to be too strenuous and possibly unsafe for non-athletic populations. The purpose of the present study is therefore to examine the validity and reliability of predicting Vo2max from a PRET incorporating a ceiling intensity of RPE 15.

Methods: Fifteen volunteers (24.7 ± 3.1 years) completed three PRETs (T1, T2 and T3) each separated by 48 hours, and one maximal graded exercise test on a magnetically braked cycle ergometer. Participants self-regulated their exercise during 3-min bouts at RPE levels 9, 11, 13 and 15, administered in a randomised order. Oxygen uptake (Vo2) was recorded continuously during each bout. Vo2 values for the RPE range 9–15 were extrapolated to RPE 20 using regression analysis to predict individual Vo2max scores. The levels of agreement between predicted and actual Vo2max scores, and the trial-to-trial predicted scores were quantified via the 95% limits of agreement (LoA) technique and an intraclass correlation coefficient (ICC).

Results: The mean values for actual Vo2max (39.8 ± 5.4 ml/kg/min) and those predicted from the three PRETs (T1, 38.9 ± 5.5; T2, 37.2 ± 6.3; T3, 38.0 ± 6.8 ml/kg/min) were not significantly different (p = .326). The LoA between actual and predicted Vo2max were -0.9 ± 12.3, -2.5 ± 11.2, and -1.8 ± 9.5 ml/kg/min, for T1, T2 and T3, respectively. Importantly, 60% (T1) 67% (T2) and 80% (T3) of participants had predicted values that were within ± 5 ml/kg/min of their actual Vo2max. The consistency of the predicted Vo2max values was reflected by LoA of 1.6 ± 9.7 ml/kg/min (T1 – T2) and -0.8 ± 8.2 ml/kg/min (T2 – T3) and corresponding ICCs of 0.66 and 0.80.

Conclusion: Our findings have demonstrated that following practice trials, predictions of Vo2max from a 9-15 PRET were, for most participants, in close agreement with actual values. Given that this modified PRET is shorter and safer than those used previously, its potential as an assessment and monitoring tool for various non-athletic populations has been established. Further research along these lines is on-going.

BENEFITS FROM A PREVENTIVE HEALTH TRAINING <COMBINED> WITH ELEMENTS FROM GOLF SPORT

KAINDL, A., HANSEN, S., HERWEGEN, H.

INSTITUTE OF SPORTS MEDICINE & INSTITUTE FOR TEACHING AND RESEARCH IN GOLF

Purpose: Based on the demand for building up health resources and according to the guidelines of German health insurances, a preventive health program with elements of golf was developed in order to reduce lack of physical activity by health-oriented exercises as well as to promote physical, mental and psychosocial health resources and strengthening and mobilization of the trunk. In order to accomplish the goals of preventive health training, the health- promoting aspects of golf haven't been considered yet. A preventive health training combined with elements from the golf sport was developed. The purpose of this study was to evaluate the benefits of a preventive health training intervention which included golf elements due to motor function and perception.

Methods: The benefits were analyzed in a controlled study (n=22). The intervention period took eleven weeks, in which participants performed a weekly training session and an controlled additional voluntary training program at home. The control group did not participate in the training program. Strength, flexibility, coordinative and relaxing exercises with elements from the golf sport were practiced according to preventive guidelines. Test and retest followed via questionnaire in order to record the physical condition, perception and muscle function.

Results: The subjective health perception increased in the physical dimension by 7,5 % and the mental did not change considerably. The strength ability of the trunk flexor advanced by 23,3% (p≤ 0.001). Flexibility did not change considerably. Increase of physical activity (6,3 ± 4,7 to 10,2 ± 9,2 hours per week) and reduction of reasons for physical inactivity (e.g. motivation, p=0.0039, uncertainty reduce, p=0.022) improved the movement status.

Conclusion:

The training group was able to build up health- promoting resources by participation in the preventive health training with elements from golf sport compared to the control group. The comprehensive guidelines of health insurances regarding preventive measures have been largely fulfilled.

This pilot study encourages new developments of health- promoting programs in prevention and rehabilitation focussing on reduction of weight, stress management, or children's health training.

ON TRANSIENT KINETICS OF PULMONARY OXYGEN UPTAKE AS AN ESTIMATOR FOR HEALTH-RELATED FITNESS

HAMASAKI, A., OKOUCHI, K., KOGA, S., ARIMA, S., NETSU, M., MITSUZONO, R., HIRAKOBA, K.

1. KATSUURA ORTHOPAEDIC CLINIC, 2. INTERNATIONAL SPORTS MEDICINE INST, 3. INST HEALTH & SPORTS SCI, KURUME UNIV, 4. DEPT HUMAN SCI. & GRAD SCH LIFE SCI & SYS ENG., KYUSHU INST OF TECH, FUKUOKA

Introduction: The time constant of phase II in pulmonary oxygen uptake on-kinetics (phase II VO2tau) during cycling is known to be approximately 30 s in healthy young subjects. The level of phase II VO2tau is likely to reflect a balance between oxygen supply and utilization in exercising muscle. In patients with peripheral arterial disease (PAD; Bauer et al., 1999) and insulin-dependent diabetes mellitus (IDDM; Regensteiner et al., 1998), a longer phase II VO2tau has been reported. This may be attributed to limited peripheral blood flow (PAD) and metabolic abnormality (IDDM), respectively. Therefore, we attempted to examine the association between change in phase II

VO2tau and changes in anthropometric and physiological variables in order to determine whether phase II VO2tau might be a good estimator for evaluating health-related fitness.

Methods: Fifteen male subjects (aged 26 to 50 yrs) doing no regular physical training participated in this study. They were asked to perform low-intensity long-duration (>60 min) training in the form of walking exercise 3-4 times a week for 12 weeks. We prospectively collected data on aerobic fitness (VO2max), phase II VO2tau and variables related to glucose and lipid metabolism at pre-, mid- and post-training periods every six weeks from the beginning of the training. Anthropometric variables were also measured at the same interval periods.

Results: There were significant decreases ($P<0.05$) in anthropometric variables (abdominal circumference; thickness of visceral fat; waist to hip ratio) in the pre- to mid-training periods, thereafter, no significant changes were noticed. Similarly, VO2max increased significantly during the pre- to mid-training period ($P<0.01$), but not during the mid- to post-training portion. In contrast, phase II VO2tau remained unchanged from pre- to mid-training, but a significant reduction ($P<0.05$) was measured at the post-training point. In addition, the same pattern of change, as a function of training, was observed for HOMA-IR, triglycerides (TG) and high-density lipoprotein (HDL).

Discussion: Changes in phase II VO2tau resulting from low-intensity training were found to be independent of changes in VO2max (Fukuoka et al., 2002) and anthropometric variables; however, the changes corresponded to changes in glucose and lipid metabolism. The improvement of phase II VO2tau is inferred to be the result of regular physical activity even in the absence of increased VO2max and reduced body fat. From these findings, we conclude that phase II VO2tau may serve as a reliable estimator for evaluating health-related fitness, as viewed from an aspect different from the commonly used parameter of VO2max.

COLD WATER DOES NOT INFLUENCE PERFORMANCE OF SELF RESCUE IN SEA KAYAK

AADLAND, E.

SOGN OG FJORDANE UNIVERSITY COLLEGE

Introduction: Sea kayaking has become a popular sport and recreation activity in all seasons. However, accidents in sea kayak often occur when kayaking alone and capsizing in cold water. In these situations ability to carry out a self rescue may be essential for surviving. As cold water has detrimental effect on muscular strength, manual dexterity, mental functioning (Giesbrecht & Bristow, 1992; Baker & Atha, 1981) and may lead to severe hypothermia, it is one of the main treats for capsized sea kayakers. Hence, wet suit or dry suit is recommended clothing. However, in some situations these suits are less practical and comfortable than lighter clothing. Hence, the objective of this study was to examine how cold water influenced the performance of self rescue in sea kayak wearing light clothes.

Methods: A total of 14 subjects ((mean ± SD) 21,9 ± 3,1 years, 7 women) completed the study. The self rescue procedure used was the standard paddle float self rescue. The study had a crossover design. All subjects practised the rescue in a swimming pool. After that they completed one test in the swimming pool (water temperature of 30,5 ± 2,0 C°) and one test in the sea (water temperature of 10,2 ± 0,4 C°) wearing the same light clothes. Time to complete the rescue, error in the procedure, heart rate and the subject's expectations and experiences of the rescue (one to five scale) was assessed.

Results: No differences were found in time to complete the rescue (169,9 ± 32,9 vs 168,6 ± 34,0 seconds; NS), error in the procedure ((N)1,6 ± 1,2 vs 2,1 ± 1,5; NS) or heart rate (141,6 ± 18,3 vs 140,2 ± 17,0 beats/min; NS) between the procedure carried out in the swimming pool and sea, respectively. Subjects judged the rescue carried out in the swimming pool to be easier to execute than the rescue carried out in the sea ($p = 0,014$), but the latter was judged to be easier to perform than expected ($p = 0.003$).

Discussion: Young, healthy women and men performed the standard paddle float self rescue just as good in cold water as in warm water wearing light clothes. Subjects had sound expectations to the level of challenge of executing the procedure in cold sea water. Even though sea kayaking in cold water wearing light clothes may compromise safety, the study shows that sea kayaking wearing light clothes in relatively cold water may be reasonable. However, every single kayaker must do sound judgment in different situations, based on the individual's accepted risk level, weather conditions, water temperature, equipment, kind of trip and competence.

COMPARISON OF PHYSIOLOGICAL AND METABOLIC RESPONSES TO PLAYING NINTENDO WII SPORTS AND BRISK TREADMILL WALKING

WILLEMS, M., BOND, T.

UNIVERSITY OF CHICHESTER

Introduction: Health problems (e.g. type 2 diabetes) have been clearly linked with a lack of physical activity (Booth et al., 2000). Interactive game play may provide an opportunity for increasing physical activity in social-recreational and home environments. Therefore, the aim of the study is to analyse physiological and metabolic responses whilst playing games on the Nintendo Wii Sports (i.e. tennis, baseball and boxing) and compare those responses with brisk treadmill walking.

Methods

Ten participants (3 females, 7 males, 21±1 years; 73.9±12.0 kg; 1.76±0.06 m) walked briskly at a self-selected pace (6.1±0.6 km•h-1, 3x10 min, 5 min rest periods) or played tennis, baseball and boxing in similar time sequence. Exercise time was chosen to match recommendations for 30 min as a minimum requirement for physical activity in one session (Haskell et al., 2007). Physiological and metabolic responses were measured with a portable metabolic system (Cosmed K4b2) and averaged for each 10 min of activity. These responses were similar for each 10 min bout of walking and averaged to provide an overall walking response. One-way ANOVA with post-hoc paired samples t-tests were used for data analysis with significance level set at $P < 0.05$.

Results: There was a trend for the heart rate in tennis to be lower than boxing ($P=0.068$) and walking ($P=0.058$). Heart rate for baseball was 24 beats and 25 beats lower than boxing ($P=0.013$) and walking ($P=0.011$). Heart rate for boxing and walking was similar. Minute ventilation was lower for tennis and baseball ($P<0.05$) compared to boxing and walking. Boxing had a larger oxygen uptake than tennis ($P=0.026$) and baseball ($P=0.004$) but was similar as walking ($P=0.318$). Brisk walking had higher oxygen uptake than tennis ($P<0.001$)

and baseball (P<0.001). Boxing had higher energy expenditure than baseball (P=0.019) but was not different than tennis (P=0.085) and walking (P=0.503). Fat oxidation was only higher in walking compared to tennis (P=0.004) and baseball (P=0.003) with no differences between sports. Carbohydrate oxidation was not different between brisk treadmill walking and Nintendo Wii Sports boxing (P=0.085) or between sports. RER values were not different between brisk treadmill walking and Nintendo Wii Sports (P=0.714) or between sports.

Discussion: Game play in young-adults with Nintendo Wii Sports boxing resulted in similar physiological and metabolic responses than brisk treadmill walking. Assuming that brisk walking is of sufficient intensity to provide health benefits, game play of tennis and baseball with Nintendo Wii may not necessarily meet requirements for physical activity to provide health benefits.

EFFECTS OF MUSCLE CONTRACTION TIMING DURING RESISTANCE TRAINING ON VASCULAR FUNCTION

OKAMOTO, T., MASUHARA, M., IKUTA, K.

HEALTH SCIENCE AND APPLIED PHYSIOLOGY

Introduction: Muscle contractions in normal resistance training are performed by eccentric (lowering phase) and concentric (lifting phase) muscle contractions. However, the difference in effects of timing of muscle contraction during resistance training on arterial stiffness is unknown. The present study investigated the effect of muscle contraction timing during resistance training on vascular function in healthy young adults.

Methods: Thirty healthy men were randomly assigned to group of resistance training with quick lifting and slow lowering (ERT, n=10), group of resistance training with slow lifting and quick lowering (CRT, n=10) and sedentary groups (SED, n=10). The ERT and CRT groups underwent 2 supervised resistance training sessions per week for 10 weeks. The ERT group performed the on set of 8 to 10 repetitions with 3 sec eccentric and 1 sec concentric muscle contractions. In contrast, the CRT group performed the on set of 8 to 10 repetitions with 1 sec eccentric and 3 sec concentric muscle contractions.

Results: Brachial-ankle pulse wave velocity (baPWV) after ERT did not change from baseline. In contrast, baPWV after CRT increased from baseline (from 1049 +/- 37 to 1153 +/- 30 cm/s, $P < 0.05$). No significant changes in flow-mediated dilation were observed in the ERT and CRT groups. These values did not change in the SED group.

Conclusion: These findings suggest that although both training does not deteriorate a vascular endothelial function, resistance training with quick lifting and slow lowering (i. e. ERT) prevent the stiffening of arterial stiffness.

BASKIN: A SPORT FOR EVERYBODY

FRATTINI, G.

UNIVERSITA' CATTOLICA DI MILANO

G. Frattini[1],A. Ajani[1], A.Bodini[2], C. Galvani[1], G. Frattini[1], F. Cereda[1], M. Mondoni[1]

[1]Motor Sciences and Sport, Catholic University of Milan, Italy

[2]Associazione Baskin, Cremona, Italy

Introduction: Baskin is a new sport activity, projected and realized in Cremona, Italy. It was created to allow differently and normally skilled people to play together in the same pitch. The word Baskin is the combination of the words basket and integration, not only meant for disabled and normally skilled people, but also for different sexes.

Innovations and analogies compared to ordinary basketball

The idea and principles of ordinary basket are maintained the same. Anyway there are some differences, which I point out in the part below:

- the number of baskets changes to 4; 2 on the short side and 2 on the borders of the centre line. They have different heights so everybody has the actual opportunity to score: the ones on the short side measure 3.05 m, the other measure 2-2.20 m. Under the ones on the centre line even lower baskets (1-1,20 m) can be placed.
- the conventional size of the court is 28 x 15 m, but it's not mandatory, it can be varied according to needs, contexts and situations.
- there are 2 semicircle shaped areas with a radius of 3 m and they are divided in 3 sectors. These divisions are marked with adhesive tape.
- the match is divided in 4 games, with stops in the same cases as real basket, and also in a player with role number 1.
- to play a Minibasket ball is used; it can be changed in case a role 1 player throws.
- there are 12 players, 6 inside a 6 outside the court. All players must play, and the total add of the shirt numbers must never be more than 23. The number on the shirt is composed by 2 digits: the first one is there to indicate the role, the second one is to distinguish players.

Players are divided, according to their physical characteristics, in classes 1 to 5:

1: a disabled player that can't move at all. He or she is always in the area of the lower basket, and when gets the ball, he or she has 10" and 2 shots to score;

2: a disabled player with all or some use of the hands but no leg use. He or she stays under the lower basket, and when he/she gets the ball then he or she can have 10" to score;

3: a disabled player with all or some use of the hands and partial leg use, which doesn't comprehend running or walking fluently. He or she can't run and has 10" to score after he or she receives the ball;

4: a partially disabled player with all or some use of the hands, and full leg capabilities (walking, running, dribbling);

5: a fully skilled basket player.

In conclusion

This new sport allows disable people to feel really integrated and socially accepted. It also has good benefits for what concerns self esteem and confidence, but also psychomotor abilities. It is an awesome weapons to fight insecurity, paranoia due to different physical condition, and other disturbing psychological statuses.

THE SIGNIFICANCE OF 'NATURE EXPERIENCES' AMONG PEOPLE WITH PSYCHIATRIC DISORDERS

VIKENE, O.L.

SOGN OG FJORDANE UNIVERSITY COLLEGE

Introduction: The aim of this study was to reveal how patients with psychiatric disorders experience participating in different outdoor activities and, moreover, to understand whether activities in 'nature' can enhance their quality of life.

Method

The study had a qualitative design. Participant observation and in-depth interviews were used. Six patients from a district psychiatric centre took part in a minimum of three days to maximum six days of outdoor hikes during a period of three weeks. The participants suffered from complex psychiatric conditions (e.g. depression, psychoses, personality disorders, and addictions). Their age varied between 18-71 years. The trips were organized in early autumn with a focus on good outdoor locations in the landscape of Sogndal, a small town in the western part of Norway. The trips consisted of short hikes, including a rest by a campfire with good food and a selection of outdoor activities.

Analysis/Discussion: In order to explain outdoor experiences, several theories can be applied. The environmental-psychological perspective, which attempts to explain the connections and experiences between humans and the physical environment, is a natural choice. Central to environmental-psychological research is the evolutionary perspective. It assumes that humans are adapted through evolution to be living in a natural environment. This perspective looks at which types of environment possess recreational qualities with regards to human health. Several studies have found evidence indicating that humans adopt a more positive emotional condition after having experienced natural surroundings when compared to urban surroundings (Ulrich et al. 1991). One of the participants, 'Hanne', seems to support this research. When asked about how she experienced being in the outdoors, she answered: 'Feel calm, is not restless. It gives me peace in a strange way. Calm and at peace with nature and myself. I don't quite know how to explain it. Feel completely calm.' This calm was also accentuated by other participants in the group. The evolutionary perspective of environmental-psychology provides an answer to why nature has a beneficial and calming effect on humans. However, this approach has problems to articulate how this is experienced by the individual. To better understand the experiential aspects of the participants, a phenomenological perspective is established. The phenomenological perspective, with its focus on the body and its close relation to the environment, can provide us with an understanding of the ways in which a person experiences the surroundings. The study reveals that psychiatric patients with serious disorders, experience participation in outdoor activities in a positive way. Hence, nature and outdoor activities can be integrated into everyday life in treatment of psychiatric patients.

EUROPEAN BEST PRACTICES AND POLICIES FOR PROMOTION AND IMPLEMENTATION OF ADAPTED PHYSICAL PHYSICAL ACTIVITY FOR ELDERLY PERSONS RESULTING FROM THE THENAPA II NETWORK

RUTKOWSKA, I., NIEMIRO, A., VAN COPPENOLLE, H., DJOBOVA, S., MORGULEC-ADAMOWICZ, N.

ACADEMY OF PHYSICAL EDUCATION IN WARSAW, FACULTY OF KINESIOLOGY AND REHABILITATION SCIENCES, K. U. LEUVEN, BELGIUM

Introduction: The populations of Europe is ageing. Data shows that total population of people over 65 increased 12,86% between 2002 and 2025. Nearly 37% of the European population will be aged 60 years or more in 2050 [EC, 2006]. Although there is some awareness about the benefits of physical activity and many of the issues regarding elderly persons are being discussed nowadays, there is still a long way to go to achieve full awareness and inclusion of older adults and especially older disabled people. The challenge is to expand the concept of an active lifestyle for all elderly persons.

Methods: During three years experts in the domain of ageing and disability from 27 European countries worked together to face this challenge. The project has reviewed the information and statistics, gathered by all the partners on good practices and policies extending throughout Europe. As a network THENAPA II developed many products that facilitate the process of awareness rising in the domain of APA for the Elderly.

Results: This research made the identification and the fulfilment of relevant educational programmes in the students' curricula. In turn these programmes have to motivate students from different academic domains to work with and for the elderly population and at the same time – to help expand the concept of active lifestyle for the elderly [THENAPA II, 2008].

Our data showed that although many good practicises were presented, not many programmes were exclusive for elderly people with a disability. To better serve the ultimate goal which is to motivate all older adults, regardless their abilities, to participate in different physical activities, the following products were developed [THENAPA II, 2008]:

-the DVD "Never too old to be active. The joy of movement" contains three motivational movies that are meant to convince elderly themselves to participate in Adapted Physical Activities.

-"Active Ageing Activity Cards" are an excellent tool for everyone who wants to organize an exercise session for older adults with or without disabilities.

Those products complement each other; their specification gives a possibility to reach not only one type of end-user, but a whole spectrum of other potential users.

Another product is the Curriculum of The European Master Programme in Adapted Physical Activity for the Eldery. The Curriculum includes 11 modules that aim in developing competencies for a variety of specialists.

Recommendations have been developed by as part of the THENAPA II project. The Network recommends the European Commission that all EU member states should implement its findings under 3 different headings: (1) the policy, (2) research and/or education programmes and (3) the elderly persons with/without a disability.

EXPERIENCE OF USE OF PHYSICAL CULTURE DEVICES DURING REABILITATION OF 4-7 YEAR-OLD CHILDREN WITH INFANTILE CEREBRAL PARALYSIS

SHKLYARENKO, A., KOVALENKO, T., ANISIMOVA, T., PASHKOVA, L.

VOLGOGRAD STATE UNIVERSITY

Present research actual continuity. Infantile cerebral paralysis has many clinical presentations. To overcome clinical appearances of this disease many scientific research of different effectiveness were carried out. Infantile cerebral paralysis severity depends on disordered motor function evidence which is mainly caused by abnormal distribution of muscular tonus and dystaxia.

Study methods and management. The research was carried out in the biomedical department of the Slavenskiy-on-Kuban Pedagogical State Institute and in the physical education and sanative technologies of the Volgograd State University. The research presents methodology of use of physical culture devices during rehabilitation of infantile cerebral paralysis taking into consideration their physiological characteristics and capacities. The results of five-year exercise according to individual rehabilitation program for 4-7 year old children (18 people) with spastic cerebral paralysis of minor and moderate severity were generalized.

Research results and their discussion. The offered program including therapeutic exercises, mechanotherapy and massage contributed to the desorded motor function decrease, motor activity increase, improvement of daily living activities of children with cerebral paralysis of minor and moderate severity.

Physical exercises with the use of applied, breathing, overall developing, muscle-strengthening and speed exercises correcting faulty positions and deformations are aimed at antagonists` reciprocal interrelation restoration, rise in inferior and superior extremities mobility, movement coordination, equilibrium, locomotor and cardio-respiratory apparatuses fitness improvement. A specific importance was brought to mechanotherapy as one form of remedial gymnastics having an overall and local influence upon infantile body suffering from cerebral paralysis. Mechanotherapy was practiced on different training stimulators such as trampoline, balancing platform, cinder track, fitness cycle, etc.

Conclusions:

1. The offered rahabilitation program for children of preschool age with spastic forms of cerebral paralysis of minor and moderate severity with the use of remedial gymnastics, massage and mechanotherapy proved its high effectiveness.

2. Five-year practice of physical rehabilitation exercises has significant influence on locomotor and cardio-respiratory apparatuses fitness improvement for children of preschool age with spastic forms of cerebral paralysis of minor and moderate severity. These results are based on improvement of power endurance rate of abdominal muscles and support ability of inferior extremity.

3. Positive changes in operant behaviour and manipulative capability factor structure of children with spastic forms of cerebral paralysis of minor and moderate severity were diagnosed; this modification shows differentiation processes in central nervous system.

QUALITY OF LIFE IN ELDERLY MEN WITH CHRONIC CORONARY ARTERY DISEASE: EFFECT OF COMBINED EXERCISE TRAINING

JANCIK, J., DOBSAK, P., TOMICKOVA, J., POCHMONOVA, J., SIEGELOVA, J., PANOVSKY, R.

FACULTY OF SPORTS STUDIES MASARYK UNIVERSITY (BRNO, CZECH REPUBLIC), DEPARTMENT OF FUNCTIONAL DIAGNOSTICS AND REHABILITATION, ST.ANNA FACULTY HOSPITAL (BRNO, CZECH REPUBLIC)

Introduction: In recent years, health-related quality of life (HRQoL) has been increasingly used as an indicator of health outcome.The aim of this study was to evaluate the effect of three months lasting combined endurance/resistance training on the HRQoL in elderly men with chronic coronary artery disease (CAD).

Methods: 26 men older than 65 years with stable chronic CAD (mean age 70 ± 5 years, mean body weight 86,5 ± 11 kg, mean height 173 ± 5 cm, EF 48,5 ± 9%, were examined before and after three months lasting aerobic training combined (from 3rd week in the course) with resistance training.

Symptom-limited spiroergometry was provided before and after the training period. The first spiroergometry was applied for the evaluation of anaerobic threshold to decide on the aerobic training intensity. Load intensity for the resistance training phase was determined by the method of 1-RM (30-60%). The training (exercise unit) was performed three times a week. The impact on quality of life was measured using the Seattle Angina Questionnaire (SAQ).

Results: It is concluded that the all 5 SAQ dimensions were significantly better after the training. Physical limitations (67 ± 25 vs. 76 ± 26**), stability of symptoms (67±26 vs. 82 ±18*), frequency of symptoms (73± 20 vs. 82 ± 18**), treatment satisfaction (84 ± 17 vs. 92 ± 21**) and disease perception (62 ± 20 vs. 73 ± 20**). Peak exercise oxygen uptake (VO2peak) increased from 18,6 ± 3,1 to 19,8 ± 4,0** ml. kg-1.min-1 (*P < 0.05, ** P < 0.01, Wilcoxon).

Discussion: The Seattle Angina Questionnaire is a valid and reliable instrument that measures five clinically important dimensions of health in patients with CAD. (Spertus, 1995). CAD negatively affects HRQoL. In patients with CAD, age and sex independently affected the HRQoL. Older patients had worse HRQoL. (Unsar et al., 2007) In recent years was shown, that one-sided preference of endurance training in older age was not able to satisfy all requirements for maintainence of the strength necessary for satisfactory quality of life. (Macek et al., 2006). In our study three months lasting combined endurance/resistance training significantly improves quality of life and aerobic capacity in elderly men with chronic coronary artery disease. There were no exercise-related adverse events during exercise training. Combination of strength and endurance training seems to be the most effective training schema in older persons.

LOWER LIMBS COMPOSITION AND JUMPING PERFORMANCE IN CHILDREN AND ADOLESCENTS WITH DOWN SYNDROME

GONZALEZ DE AGÜERO, A., VICENTE-RODRIGUEZ, G., CASAJUS, J.A.
UNIVERSITY OF ZARAGOZA

Introduction: Jump power is associated to the composition (lean, fat masses and bone masses) of lower limbs in healthy population(1). Lower levels of strength in quadriceps and hamstring have been observed in children and adolescents with Down syndrome(2). We aimed to elucidate whether children and adolescents with DS have impairments in jumping performance and to find the possible relationships with lower limbs composition.

Material and methods: 30 children (17 male) with DS, mean age 14.7±3 yr. were compared with 30 healthy and without mental retardation (MR) children, matched in age and sex. The total body lean mass and lower limbs bone mineral content (BMC), fat and lean masses of the subjects was measured using dual energy X-ray absorptiometry (DXA). The jump performance was assessed throw the height jumped in counter movement jumps (CMJ) and Abalakov (ABA) jumps. Differences in the jumped height between groups (male and female separately, and as a whole) were established using Student's unpaired t test, analysis of covariance was performed to test the differences in the upper and lower limbs lean mass using height and Tanner maturational status as covariates. Pearson's correlations were applied to identify the relationships between lower limbs BMC, fat and lean masses and both jumps.

Results: Significant higher CMJ and ABA jumped height was found in children without DS ($p<0.01$). Children without DS had higher lean mass and BMC in the lower limbs when both sexes were compared as a whole group and also separately ($p<0.05$); there were no differences in the fat mass. Lean mass and BMC in the lower limbs were correlated in both groups (SD $r=0.93$; control $r=0.92$, both $p<0.01$); also fat mass and BMC had a relationship in the group with DS ($r=0.39$, $p<0.05$). CMJ and ABA jumped height was highly correlated with BMC (CMJ $r=0.47$, $p<0.01$; ABA $r=0.55$, $p<0.01$), lean (CMJ $r=0.46$, $p<0.01$; ABA $r=0.56$, $p<0.01$) and fat masses (CMJ $r=-0.68$, $p<0.01$; ABA $r=-0.71$, $p<0.01$) in the control group. In the group with DS, height jumped in the CMJ was correlated with BMC and lean mass ($r=0.45$; $r=0.39$, $p<0.05$), and in the ABA with BMC ($r=0.45$, $p<0.05$).

Discussion: Children with DS showed less lean mass and BMC in the lower limbs than their peers without MR; the jumped height of this population is also lower. CMJ was similarly related with lower limbs composition in both groups; however, the lack of relationship between ABA jump and lean mass could be explained by the technical factor associated to this kind of jump.

STATISTICS BETWEEN WINNING AND LOSING TEAMS BY COMPETITION LEVELS IN VOLLEYBALL - WORLD CUP AND CHAMPIONSHIP 2007

JOÃO, P., MOTA, M., MESQUITA, I., SAMPAIO, J.
1. RESEARCH CENTER FOR SPORTS SCIENCES, HEALTH AND HUMAN DEVELOPMENT (CIDESD) PORTUGAL, 2. FACULTY OF SPORT SCIENCES AND PHYSICAL EDUCATION – UNIVERSITY OF PORTO, PORTUGAL.

Introduction: Game analysis (GA) allows for the interpretation of the organization of teams and the identification of game statistics so as to improve competitive performance. Volleyball game-related statistics are used to identify and control team and individual performances, aiming to find a way to score two more points than the opposing team. The characteristics identified in the diverse competition levels might present specificities for each game level. Therefore, the purpose of the present study has been to identify the game-related statistics that allow for the discrimination between winning and losing teams in competition levels in volleyball.

Methods: The statistics of all the games (n=344) of the diverse World championships 2007 (including all levels of competition and both genders) were analyzed using the Software VIS of the 'score box' of the International Volleyball Federation (FIVB) by undertaking the analysis of the discriminating function (DF) so as to identify the indicators that contributed more to establish the maximum difference between victories and defeats. Through the structural coefficients (SC), we have identified the game-related statistics that best discriminate the levels.

Results: Our results showed that the obtained functions in this discriminating analysis were all statistically significant ($p<0.05$) and classified correctly in 82.3% of the cases. As there are high values of quality reception and excellent sets in the senior teams, they obtained lower values in the continuity reception and faults sets. At the same time, the junior teams presented higher values of continuity reception. Thus presenting a possible explanation for the occurrence of faults sets, seeing as they are two actions preceded by the opponent's service. The structure coefficients identified team continuity reception (SC=-0.35) and faults sets (SC=-0.30) for function 1. For function 2, only the excellent digs (SC=0.32) contributed to discriminate the groups.

Discussion: The results are going to suggest that the greater the experience with reference to age and competition level of the players, the better the levels of reception. Contrarily, the lower the age of the players and the competition level is, the lower the number of continuity receptions.

A possible explanation for these divergences in the values found in the present study may result from the differences in the tactical-technical capacity between competition levels, resulting from the differentiated qualities in the reception between extreme levels.

The ensuing results of the seniors present higher values in excellent distribution, slightly lesser in relation to the following variables; the same takes place for the continuity sets and the faults sets.
These profiles may better help coaches in their preparation according to this specificity, allowing teams to be ready to control these variables in competitions.

STATISTICS BETWEEN WINNING AND LOSING TEAMS BY COMPETITION LEVELS AND GENDER IN VOLLEYBALL

JOÃO, P., VAZ, L., MOTA, M., MESQUITA, I., SAMPAIO, J.

1. RESEARCH CENTER FOR SPORTS SCIENCES, HEALTH AND HUMAN DEVELOPMENT (CIDESD) PORTUGAL, 2. FACULTY OF SPORT SCIENCES AND PHYSICAL EDUCATION – UNIVERSITY OF PORTO, PORTUGAL

Introduction: The identification of sports skills underlying high-level performances can be information of great value to volleyball coaches, thereby allowing them to establish and monitor playing patterns. The aim of this study has been to identify the volleyball game-related statistics that allow for discriminating performances by gender and level of competition.
Methods: The statistics of all the games (n=344) of the diverse World championships 2007 (including all levels of competition and both gender) were analysed using the Software VIS of the 'score box' of the International Volleyball Federation (FIVB), and involved the analysis of the discriminating function (DF) so as to identify the indicators that contribute more to establishing the maximum difference between victories and defeats. Through structural coefficients (SC), we have identified the game-related statistics that better discriminate the levels and genders.
Results: The results showed that for gender x level of competition the obtained functions in selective analysis were all statistically significant ($p<0.05$) and classified correctly in 85.6% of the cases.
The structure coefficients from Function 1 reflected team faults percentages (SC=0.39), shots spikes percentages (SC=-0.38) and continuity digs percentages (SC=0.31). Function 2 reflected excellent Digs (SC=0.31) and continuity digs (SC=0.31). Function 4 showed team faults percentages (SC=0.35) contribution for discriminating the groups. Function 5 showed the excellent digs (SC=-0.39), the faults receptions (SC=0.35) the faults digs (SC=-0.34) and Serve aces (SC=0.30) contribution for discriminating the groups.
For the team faults percentages, it may be observed that there are differences between men and women at different levels of competition. The majority of the teams lose many points through the faults made. It is possible to observe that, in men's Volleyball, the juniors present elevated team faults percentages, following the same pattern as the seniors and, finally, the youth. In the female Volleyball, the seniors present elevated team faults percentages, the juniors an intermediate figure and the youth present a limited number.
Discussion: The results show that the use of this study can help coaches to understand better the differences between players – the different genders of players and level of competition – and better regulate training sessions and competition.
As the game level increased, so did the risk, because not taking a risk can mean losing a point. In the game of senior Volleyball there is a greater error because continuity may provide an opening for the adversary to score. Men versus women: men fail more probably because they also risk more and in so doing end up by increasing the possibility of losing.
It is worthwhile pointing out that the success rate in the attack is almost always higher for seniors, regardless of gender, and decrease gradually until the younger players.

THE EFFECTIVENESS OF BASKETBALL PLAYERS IN OFFENSE, FOLLOWING AN OUTSIDE GAME, THROUGH VIDEO ANALYSIS

TSAMOURTZIS, E., MAVRIDIS, G., KARIPIDIS, A., ROKKA, S., SFIGGOS, N., ATHANAILIDIS, J.

DEMOCRITUS UNIVERSITY OF THRACE

Introduction: An offensive strategy can include movements like shots with screen, without screen or shots near of far from the basket (Wissel, 2006). The outside game is part of the control offense and is based on shots performed from medium or far distances. The effectiveness -or not- of a shot depends on the amount of pressing applied on the defense, as well as on the personal characteristics of the player shooting (Smith & Spear, 1981). Many coaches prefer developing strategies far from the basket, so that all players can shoot (Gillen, 1993). The aim of this study was to analyze the outside game in European Championships.
Methods: The sample consisted of 80-videotaped Basketball games from the 2003, 2005 and 2007 Mail European Championships. The phases recorded were the outside game and the offenses with and without screen, as well as the effectiveness of the above offenses. To define effectiveness, the authors considered the successful or missed two-point and three-point shots, the won offenses and the turnovers. The following equipment was used: A video set to record the games shown on various channels; a video card for the digitalisation of the games; A computer (P/C); the "Sportscout" programme for the analysis of the digital video. For the statistical analysis of the data, the method used was the analysis of frequencies and the non-parametric test x2. The $p< .05$ was defined as level of significance.
Results: The outside game took up 65% of the executed offenses. 4 out of 10 of the offenses far from the basket were realized after a screen, while 6 out of 10 without a screen. The teams performed a higher score of two-point and three-point shots, after a screen. The dominant offense with screen was the pick and roll, while the most frequent offense without screen was the 1 on 1.
Discussion: The dominant offensive tactic without screen was the offense 1 on 1, which is in accordance with Tavares et al., 2003. As for the offenses without screen, the dominant element of control offense was the pick and roll (Ociepka, 2004; Filipovski, 2005). Both the distribution of the offensive strategy and the effectiveness of the players are similar to those of previous researches (Tavares et al., 2003). The development of an offensive strategy must satisfy players, coaches and fans, but it must also be successful (Wissel, 2006).

SPACE-TIME COORDINATION DYNAMICS IN BASKETBALL: INVESTIGATING THE INTERACTION BETWEEN THE TWO TEAMS

BOURBOUSSON, J., SEVE, C., MCGARRY, T.

NANTES ATLANTIC UNIVERSITIY

Introduction: Bourbousson, Seve and McGarry (submitted) reported an investigation of space-time patterns of basketball players in terms of the couplings among player dyads. The present study examined basketball game behaviour from analysis of the interaction between the two teams, addressing whether basketball subscribes to dynamical system descriptions at different levels of analysis.

Methods: Six game sequences were selected for analysis from which the x-y coordinate data of each player was obtained. From these data the longitudinal and lateral movements of the teams were then analyzed using two metrics, the centre of gravity and the stretch index. The former assesses the central position of a team and the latter the dispersion of a team about its central position. The relative phase between the centres of gravity, as well as the stretch indexes, and a new measure termed the differential stretch index (i.e., the difference between the stretch indexes of the two teams) were then used as collective variables to assess the interaction between the teams. Investigation of correspondences between game events (i.e. shot attempts and ball possession) and the collective variables used was realized.

Results: In regard to the phase analyses, an in-phase relation between the teams was evidenced with more stability reported for the longitudinal direction than for the lateral one. The differential stretch index in contrast demonstrated two separate and stable properties for both the longitudinal (-0.6 m and 0.8 m) and lateral directions (-0.4 m and 0.6 m). In the investigation of correspondence between game events and collective variables, qualitative analyses identified two classifications of shot attempts: individual shots and team shots, with the second shot type being produced seemingly just after a large perturbation in relative phase between centres of gravity when measured in the lateral direction. Major variations in the differential stretch index were related with changes in ball possession.

Discussion: The different results obtained by using different metrics and collective variables demonstrate that the information obtained from the analysis is much informed by the particular indicator used. The relative phase perturbations of the centres of gravity were forecasting shot attempts when produced by team work. This indicator might well contain useful information for sports practitioners. Otherwise, the supposition that in general the attacking team tends to expand and the defending team contracts was supported by the differential stretch index, with the teams switching between expansion and contraction in alternating fashion with changes in ball possession . In sum, the space-time patterns of basketball teams, while different with regard to the particular indicators used, were nonetheless consistent with a unified description of self-organizing behaviours in sports competition.

COMPARISON BETWEEN WOMEN'S AND MEN'S GAME AT RUGBY WORLD CUP LEVEL

VAZ, L., MOUCHET, A., CARRERAS, D.

1. RESEARCH CENTER FOR SPORTS SCIENCES, HEALTH AND HUMAN DEVELOPMENT (CIDES) – PORTUGAL, 2. UNIVERSITÉ PARIS 12 - FRANCE, 3. INSTITUT NACIONAL D'ÉDUCACION FÍSICA DE CATALUNYA (INEFC) - SPAIN

No study has accounted for the comparison between women´s and men´s game at rugby world cup level. The rugby men's game has developed since 1995, so has the women's game, but while the women's game is structurally similar to that played by men in RWC 99. The aim of this study is to determine if any relationship exists between women´s and men´s game at rugby world cup level. Archival data report to game-related statistics from thirty matches played in Women´s RWC 2006 and forty-eight matches played in Men´s RWC 2007. We analyzed and compare matches during the different stages (pool, knockout and final stages) of RWC finalist countries. The statistical review and match analysis are analysed to help identify the most powerful game-related statistics to discriminate the game. In women´s RWC 2006 the average number of points per match was 39. 179 tries were scored in the 30 matches and there were six times more tries than penalty goals. The activity cycles: ball in play time averaged 41%, rucks/mauls averaged 131 per game, passes averaged 220 per game and almost 80% of all passing movements contained 2 passes or less. Open play kicks averaged 43 per game. Women set pieces: average 31 lineouts per game, 68% were contested and possession was retained on 73% of occasions. There were an average of 28 scrums per game and the possession retained was 89%. In men´s RWC 2007, the average number of points scored per match was 52. In RWC 296 tries were scored in the 48 matches, average 6.2 tries per game. 32% of tries came from lineout possession, 18% from scrum, 17% came from turnover or handling error and 15% came from opponents kick. The men´s activity cycles: ball in play time averaged was 44%, the men's game produces 40% more rucks and mauls and around 35% more passes, average 144 per game. The men´s set pieces were lineout also average 31 per game just over 60% were contested and possession was retained on 80% of occasions. There were only 19 scrums per game/RWC 2007 some 9 more than in the Women's RWC 2006. Apart from scrums - which were 33% more frequent in the men's game, all core elements were recognizably the same, but with one significant exception - kicking. While the average number of tries were similar, when it came to kicks there were huge differences between the men's game and the women's game. Kicking therefore was a far less noticeable part of the women's game with fewer kicks at goal, a lesser success rate and fewer kicks from hand during open play. What is clear therefore is that kicks at goal are less frequent and less successful than in the men's game. This also illustrates the fact that kicks over a certain distance cause considerable difficulty to many women's teams. There are some common tendencies in men´s and women´s game at rugby world cup level. The various teams may find the data of benefit in establishing benchmarks and performance indicators for future tournaments. REFERENCES I.R.B. (2006/2007) Statistical review and match analysis of Game. Dublin

RUGBY UNION GAME-RELATED STATISTICS AS A PREDICTOR OF WINNING OR LOSING TEAMS IN CLOSE GAMES

VAZ, L., SAMPAIO, J., FERNANDES, S., MAÇÃS, V., VICENTE, J., LEITE, N., GOMES, I.

1. RESEARCH CENTER FOR SPORTS SCIENCES, HEALTH AND HUMAN DEVELOPMENT (CIDES) - PORTUGAL

Studies rarely differentiate the characteristics of winners or losers in rugby union games. Rugby game-related statistics are a powerful tool to analyze teams` and players performance in different skills (Vaz, 2008). Unlike other team sports, available research is still unclear about the game-related statistics that discriminate between winning and losing teams. Only Jones et al. (2004) have identified lineout's won on oppositions throw and tries scored as statistically different between rugby union game winners and losers. The aim of this study was to identify the rugby union game-related statistics as a predictor of winning or losing teams in close games. Archival data report to game-related statistics from 135 IRB games and 207 Super twelve games played between (2003-2006). Afterwards, a cluster analysis

was conducted to establish, according to game final score differences, three different groups for the subsequent analysis. Only the close games group was selected for analysis (IRB n=64 until 15 points difference and Super twelve n=95 until 11 points difference). Finally, an analysis to the structure coefficients (SC) obtained through a discriminant analysis allowed to identify the most powerful game-related statistics in discriminating between winning and losing teams. The discriminant functions were statistically significant for Super twelve games (Xi-square = 33.8, P<0.01), but not for IRB games (Xi-square = 9.4, P=n.s.).In the first case, winners and losers were discriminated by possessions kicked, (SC=0,48) tackles made (SC=0,45), rucks and pass (SC=0,40), passes (SC=-0,39), mauls won (SC=-0,36), turnovers (SC=-0,33), kicks to touch (SC=0,32) and errors made (SC=-0,32).The minus sign denotes higher values in losing teams. Rugby union game-related statistics were able to discriminate between winners and losers in close games. The need for objective, accurate and relevant feedback about player's performance from both training and competition has led to the development of match analysis systems based on computer and video technology. Coaches can use these results for players' recruitment, team preparation and for directing the competition.

MATCH DEMANDS OF BEACH SOCCER: A CASE STUDY

SCARFONE, R., TESSITORE, A., MINGANTI, C., FERRAGINA, A., CAPRANICA, L., AMMENDOLIA, A.

1. UNIVERSITY OF MAGNA GRAECIA, CATANZARO, ITALY, 2. DEPARTMENT OF HUMAN MOVEMENT AND SPORT SCIENCES, UNIVERSITY OF FORO ITALICO, ROME, ITALY

Introduction: Despite the increasing worldwide popularity of Beach Soccer, played either at amateur and professional level, few scientific studies focused on this sport, leaving open several questions about its performance profile. Thus, the aim of this study was to examine the responses to a Beach Soccer friendly match in varsity players.

Methods: Ten male players (age 23.6±4.4 yrs; body mass 71.8±3.8 kg; height 1.77±0.05m) of the Magna Græcia University beach soccer team provided their written consent to participate in the study. The subjects were divided in two teams (1 goalkeeper, 2 defenders, 1 pivot, and 1 attacker). The beach soccer match consisted of three 12-min periods with 3-min breaks in between. During the match heart rate was continuously recorded every 5 s (Polar Team System, Polar Electro, Finland). Before the match and at the end of each period blood lactate concentrations (La; Accusport, Roche, Switzerland) and power performances (countermovement jump, CMJ; Optojump, Microgate, Italy) were measured. To estimate the intensity of efforts during the match, HR was expressed as a percentage of HRmax using 5 categories: >95%, 86–95%, 76–85%, 65–75%, <65%. ANOVA for repeated measures was used to test differences (p<0.05) between periods.

Results: Match intensity showed differences for HR categories (p=0.001) and their interaction with match periods (F(8, 64)= 4.18; p=0.0005), and La values (p=0.03). A progressive decrease of occurrence toward the end of the match emerged for HR>85% (periods: first=75%, second=61%, third=31%). A similar trend emerged for La values (periods: first=8.7±4.0mmol.L-1; second=6.7±3.8mmol.L-1; third=5.3±2.7mmol.L-1). With respect to pre-match condition (36.6±5.3cm), higher (p<0.004) CMJ performances were found at the end of the match periods (first=39.5±6.5cm; second=40.9±6.4cm; third=39.2±6.0cm).

Discussion: The present findings indicate that Beach Soccer is an intermittent sport activity that places a high load on players, with the anaerobic metabolism providing an important energy source during games. Although the marked decrease in intensity of playing might indicate that players undergo fatigue (Mohr et al., 2003), this speculation is in contrast to the increased CMJ performances of players, which might be attributed to an enhanced neuromuscular activation (Vetter, 2007). Thus, it might be hypothesized that players tend to adopt tactical strategies to spare their energies throughout the match and further studies are necessary to clarify these aspects.

CORRELATIONS BETWEEN TEAMS' HEIGHT AND GAME-RELATED STATISTICS IN YOUNG FEMALE INTERNATIONAL LEVEL BASKETBALL GAMES.

RUSSO, L., DE ANGELIS, M., VALENTI, M.

HUMAN MOVEMENT AND SPORT SCIENCE FACULTY, L'AQUILA

Introduction: Body size and height are important anthropometric factors to competitive advantage and field playing position in basketball (Carter et al., 2005; Drinkwater et al., 2008). Increasing importance is given to some game-related statistic parameters, such as 2 and 3 point field goals percentage, opponent 2 and 3 field goals percentage, number of rebounds, assist, fouls, steals, turnovers and blocks per game (Trninic et al., 1999; Gómez et al., 2008). No studies before have searched for relationships between teams' height and game parameters. Therefore, the aim of this study was to look for correlations between teams' height and game-related statistics in young elite female basketball games.

Methods

The game-related statistics from 496 matches of the Under 20 female European Championship (2005 to 2008) were examined. Teams had an average height of 181 (SD 2.00) cm and an average age of 19.34 (SD 1.34) years. Correlations between height and game parameters were assessed by Pearson correlation coefficient. The significant level was set at p = 0.05

Results: In parallel with a positive significant correlation between the percentage of the games won and defensive rebounds (r = 0.43) and total rebounds (r = 0.35), the data analysis showed positive significant correlations between the teams average height and: percentage of the games won (r = 0.34), defensive rebounds (r = 0.32), offensive rebounds (r = 0.26), total rebounds (r = 0.35), blocks (r = 0.46). Negative significant correlations was found between the teams average height and: points allowed per game (r = -0.37), opponent field goals percentage (r = -0.45), opponent 2 points field goals percentage (r = -0.40), opponent 3 points field goals percentage (r = -0.41), fouls (r = -0.32).

Discussion: In U20 female European Basketball Championship height appears to be significantly correlated with several "performance indicators" (Hughes et al., 2002) such as: assist, defensive rebounds, 2 and 3 point field goals percentage (Trninic et al., 1999; Gómez et al., 2008). The significant correlation found between average team's height and percentage of the games won emphasizes the impor-

tance of height in basketball as a performance indicator. It is therefore necessary to study other age/sex categories to have a full knowledge of all significant parameters.

HAEMATOLOGICAL CHANGES, CELL DAMAGE AND OXIDATIVE STRESS DURING A SKI-MOUNTANEERING COMPETITION

GIL, S.M., DIAZ, E., RUIZ, F., HOYOS, I., ZUBERO, J., GRAVINA, L., GIL, J.

UNIVERSITY OF THE BASQUE COUNTRY

INTRODUCTION: Blood changes and muscle cell damage have been described in many sports (Nikolaidis, 2008). Also, high intensity exercise produces oxidative stress which has been related to fatigue, damage and overtraining (Fisher-Wellman & Bloomer, 2009). Information about ski-mountaineering is scarce. Therefore, the aim of this study was to analyse the effect of a ski-mountaineering competition on blood measurements.

METHODS: 21 male skiers participated in this study. Blood samples were taken before and immediately after an official two-day ski-mountaineering competition to measure in serum: red cell count, white cell count, biochemistry, C-reactive protein, cortisol, creatine kinase (CK), aspartate aminotransferase (AST), alanine aminotransferase (ALT), γ-glutamyl transpeptidase (GGT), lactate dehydrogenase (LDH), alkaline phosphatase (AP), total antioxidant status (TAS), superoxide dismutase (SOD), glutathione reductase (GR) and glutathione peroxidase (GPx).

RESULTS: After the competition there was a decrease in the red cells (4.78 x 106/µl ± 0.0 vs 4.56 ± 0.1**), haemoglobin (15.0 g/dl ± 0.1 vs 14.2 ± 0.3**), mean corpuscular haemoglobin concentration (35.7 pg ± 0.2 vs 34.3 ± 0.3**, whereas bilirrubin (0.60 mg/dl ± 0.1 vs 1.10 ± 0.1**) increased (all maintained within normal parameters).

We also found an increase in the leucocytes (7.4 x 103/µl ± 0.3 vs 11.2 ± 0.6**), neutrophils (3.60 103/µl ± 0.23 vs 8.68 ± 0.60**) and monocytes 103/µl (0.50 ± 0.04 vs 0.90 ± 0.06**); but, lymphocytes 103/µl (2.80 ± 0.13 vs 1.50 ± 0.10**), basophyls 103/µl (0.10 ± 0.01 vs 0.04 ± 0.01*) and eosinophils 103/µl (0.40 ± 0.05 vs 0.07 ± 0.02**) decreased.

Muscle enzymes' levels were higher after the competition (CK: 173 U/L ± 20 vs 664 ± 74**, AST: 25.7 U/L ± 1.4 vs 43.0 ± 3.2** and LDH: 305 U/L ± 12 vs 402 ± 14**), together with the cortisol (6.6 µg/dl ± 0.8 vs 16.8 ± 1.0**) and C-reactive protein (0.10 mg/d ± 0.02 vs 0.65 ± 0.04**).

On the other hand the capacity of the glutation peroxidase also increased (68.13 U/l ± 26.23 vs 117.70 ± 29.58**).

*p<0.05, **p<0.05

DISCUSSION: A two-day ski-mountaineering competition produced marked haematological changes: haemolysis, leucocytosis and lymphopenia. There was also muscle cell damage and oxidative stress. It would be interesting to know if these changes may affect performance; and if so, it could be important to design interventions to lower them.

THE COL5A1 GENE AND MUSCULOSKELETAL SOFT TISSUE INJURIES

COLLINS, M., POSTHUMUS, M., SEPTEMBER, A.V., SCHWELLNUS, M.P.

SOUTH AFRICAN MEDICAL RESEARCH COUNCIL AND UNIVERSITY OF CAPE TOWN

Purpose: Genetic elements have been shown to predispose individuals to chronic Achilles tendinopathy (TEN) and anterior cruciate ligament (ACL) ruptures. The CC genotype of the BstUI RFLP within the COL5A1 gene was significantly over-represented in the age-matched (±38 years) asymptomatic controls, when compared to TEN subjects in South African and Australian populations [1;2]. Similarly, within females but not males, this genotype was also significantly over-represented in age-matched (±27 years) asymptomatic controls when compared to ACL subjects [3]. The frequency of the CC genotype of the age-matched (±27 years) asymptomatic male controls (16%) where distinctly different to the frequency of the combined male and female asymptomatic controls in the TEN studies, as well as the female controls in the ACL study (24-27%).

Aims and Methods: Considered together, these results highlight two important aspects which need further investigation. Firstly, is there a gender-specific COL5A1 BstUI RFLP genotype effect on TEN. Secondly, since the younger male controls within the ACL study had a lower CC genotype frequency is the distribution of this COL5A1 polymorphism within the controls age-dependent, particularly among males.

Results: There was no evidence that the association of the COL5A1 BstUI RFLP with TEN in the two previously published studies were gender-specific. However, when the 299 male asymptomatic controls from all studies were pooled and dived into age-group tertiles, there was a significant linear trend (P=0.047) for the CC genotype frequency amongst the male age groups, with the youngest group having the lowest (17%) and the oldest group the highest (29%). There was however a similar CC genotype content in all three female (n=251) age groups (23 to 26%).

Conclusion: Although the COL5A1 BstUI RFLP CC genotype was under-represented in females, but not males with ACL ruptures there appears to be no gender-specific under-representation of this genotype within TEN. Consequently, there is an age-dependant increase in the CC genotype of this sequence variant within a pooled group of asymptomatic male controls. The practical implication is that the selection of control groups is of critical importance when future studies of this nature are designed. Future research investigating this genetic variant as a risk factor for soft tissue injuries should consider these findings when selecting a control group.

RISK FOR "TIME LOSS INJURY" AND SKILL LEVEL AMONG 11-TO 12- YEAR-OLD MALE SOCCER PLAYERS

SEVERINO, V., GONÇALVES, R., SIMÕES, F., REGO, I., MAZZUCO, M., FIGUEIREDO, A., PÁSCOA PINHEIRO, J., COELHO E SILVA, M.

UNIVERSITY OF COIMBRA

An injury consensus definition was established under the auspices of FIFA Medical Assessment and Research Centre (Fuller et al., 2006). Risk for injury was already investigated in elite soccer (Ekstrand et al., 2004; Hagglund et al., 2003). Research in youth athletes is less abundant and still lacking in Portugal. The current study adopts the mentioned operational definition of "Time Loss Injury" [TLI] to estimate the incidence and prevalence of injuries among 11 to 12 years old Portuguese soccer players.

Based on soccer players from five clubs, the sample was composed by 62 subjects (11.0-12.9 years). At the starting month of the season players were measured in height, weight, fitness defined as lower limb muscle power (vertical jumps with and without counter movement using an ergo-jump, Bosco, 1994), 10x5-m agility test (Philippaerts et al., 2006), 20-m endurance test (Yoyo, Bangsbo, 1994) and 7-sprint test (Reilly & Poran, 2003) and four soccer-specific skills (shooting, dribbling, passing and juggling; see Figueiredo et al., 2009). The authors individually registered the number of sessions, games and respective minutes over two seasons and monitored the episodes of TLI on a weekly basis.

After baseline measurements, 58% of the sample did not registered any TLI, 24% registered two episodes and 18% three or more over two consecutive seasons. The occurrence of injuries resulted in a loss of 490 days of practices and competitions. The total amount of exposures was 13,488 sessions and 1,046,346 minutes. The incidence was 5.19 injuries per 10,000 sessions of exposure and 0.67 injuries per 10,000 minutes. Injured athletes were significantly more talented in skills (juggling; dribbling) and attained better performances in the agility test as well as in best sprint of the anaerobic protocol.

In summary, four out of every ten initiates are victims of sport injuries. The current study also suggests that being skilled is a risk factor for sport injuries. It is of interest to confirm this trend and to consider policies for developing biological readiness among talented young soccer players.

PHYSICAL ACTIVITY IN PRIMARY DYSMENORRHOEA

SANTOS, P., BALTAZAR, F., ALVES, O., MIRANDA, L., VALENTE, A., MOTA, J.

FACULDADE DE DESPORTO - UNIVERSIDADE DO PORTO

Purpose – The aim of this study is to determine the influence of physical exercise in primary dysmenorrhoea and associated symptoms.

Methodology - This analytical cross sectional study comprised 72 volunteers women, aged between 17 and 25 years, of which 37 were physically active (non-competitive) and 35 were sedentary. In order to determine the existence of dysmenorrhoea the Moos Menstrual Distress Questionnaire was applied as well as the Visual Analogue Scale Survey to measure the severity of pain. For statistical analysis chi-square test and Mann-Whitney were used.

Results – Physical Active girls had less menstrual pain compared to sedentary ones (56.8% vs 97.1% ;p <0001). Regular physical activity showed significantly, less duration (p = 0014) and intensity of menstrual pain (p = 0001). In addition, the physical active women felt less disturbs caused by menstrual pain (p = 0,018). Furthermore they felt less incapacity to accomplish to daily activities (p = 0.09) and absenteeism at work or school was lower (p = 0 , 02).

In the analysis of the symptoms associated with dysmenorrhoea, the sedentary group showed greater severity of symptoms in the categories: 'bad pain and being' (p <0001), 'fluid retention' (p = 0002), 'feelings negative (p <0001) and 'concentration' (p = 0017).

Conclusion – Our results suggest that regular practice of physical activity contributed in a positive way to improve the disorders caused by primary dysmenorrhoea.

INFLUENCE OF ORAL CONTRACEPTIVES ADMINISTRATION IN THE CAPACITY OF MUSCLE STRENGTH

SANTOS, P., VIEIRA, D., ALVES, O., MIRANDA, L., VALENTE, A., MOTA, J.

FACULDADE DE DESPORTO - UNIVERSIDADE DO PORTO

Introduction / Objectives: This study aims are twofold: (1) to determine whether the administration of oral contraceptives (OC) influences the capacity of muscle strength, and (2) to analyse if there is variation in strength levels between the initial follicular and mean luteal phases of the menstrual cycle (MC) in women who take and don't take OC.

Relevance: The knowledge of the possible influence of CO in the capacity of muscle function will enhance the sports performance and clinical practice.

Methodology: A total of 40 University students participated in this study. Two groups were assigned (young women who take CO n = 20; young women not taking regular NCO n= 20). An electronic isometric dynamometer was used to measure the maximum voluntary isometric contraction of quadricípite during follicular and mean luteal MC in both groups. T test was used for independent samples to compare the mean muscle strength and t test for paired samples, to compare the intra-group force mean differences in two phases of MC assessed.

Results: No statistical significant differecnes were found between the groups in initial follicular phase (37,86 ± 9,92 vs 34,90 ± 7,32 Kg/N; p = 0.29); and in mean luteal phase (41,43 ± 7,71 vs 40,00 ± 8,26 Kg/N ;p = 0.58). In women taking OC, there is no statistical evidence (37,86 ± 9,92 vs 41,43 ± 7,71 Kg/N ;p = 0.06) to say that there are differences in the production of strength between the two phases of MC. In women who weren't taking OC, there were found statistical significant differences in the production of strength between the two phases (34,90 ± 7,32 vs 40,00 ± 8,26 Kg/N; p = 0.01).

Discussion / Conclusion: Our results suggest that the administration of CO does not influence the capacity of muscle strength but eliminates the fluctuations in strength during the different phases of MC.

INFLUENCE OF COMPRESSION STRESS TO THE ARTICULAR CARTILAGE - AN EXTRA-VIVO STUDY USING MAGNETIZATION TRANSFER CONTRAST IMAGING -

KUDO, H., YAMAGUCHI, T., MUKAI, N., MIYANAGA, Y., MIYAKAWA, S.

NATIONAL INSTITUTE OF ADVANCED INDUSTRIAL SCIENCE AND TECHNOLOGY

Introduction: Magnetization transfer contrast (MTC) is an imaging method, which creates tissue contrast in a different manner as T1 and T2 relaxation time by the exchange of magnetization between macromolecular protons and bulk water, via cross relaxation or chemical exchange. Therefore, it may be beneficial to evaluate articular cartilage using MTC because it has abundant macromolecules and its function should be specified by macromolecular protons. We had reported the change of MTC effect in human cartilage with exercise (ECSS 2004-2008). In this study, we observed the MTC effect in bovine cartilage during mechanical compression to verify the change of MTC effect reflected behavior of articular cartilage to compression stress.

Methods: Ten 8-mm-diameter cylindrical cartilage plugs were harvested from bovine tibia for the specimens. MTC images were obtained before, during, and after application of mechanical compression using Fast Low Angle Shot (FLASH) (TR(ms)/TE(ms)/FA(deg)=11.9/3..5/30) and FLASH-MTC sequence on a 2T superconducting magnet and a 72-mm birdcage coil. The off-resonance sinc pulse was set at a frequency offset of 1.5KHz from the free proton resonance with a duration of 3msec and an amplitude of 20x10-6T as preparation for MTC images. The mechanical compression (97.6kPa) was applied with a custom-built MR-compatible pressure device. The quantitative analysis of bovine cartilage was performed with Ms/Mo. Ms/Mo was calculated as follows: Ms/Mo = SNR with MTC / SNR without MTC, where SNR is signal-to-noise ratio.

Results: The specimens had mean Ms/Mo of 0.71 before compression. The Ms/Mo of specimens with mechanical compression decreased to 0.53 ($p<0.05$) and recovered to similar level to the pre-compression after compression had been removed.

Discussion/Conclusion

We investigated the MTC effect of the bovine cartilage during mechanical compression stress. The Ms/Mo decreased under compression and recovered by removal of compression. These results suggest that water content within the cartilage changed with mechanical compression. Furthermore, this extra vivo study also provides ample experimental support for our recent in vivo study.

INVESTIGATION ON THE RISK FACTOR OF SOCCER-RELATED INJURY FROM PHYSICAL MATURATION ASPECTS

NORIKAZU, H.

FACULTY OF SPORTS SCIENCES, WASEDA UNIVERSITY

Introduction: The increasing of mechanical stress which forced during the training and the match is thought to be the risk factor of the soccer-related injury during puberty. It has been reported that the increase of mechanical stress depends on the physical maturation and large individual difference in physical and biological maturation exists during puberty. These findings led us to propose two hypothesizes. First, early-matured adolescents, who may be stronger and bigger, are more likely to suffer from acute traumatic injury. Secondly, it is thought that intensive training may be overly stressful for late matured players as compared to early and average matured players because of their physical weakness. Therefore, in this study we examined the relationship between injury rates and biological maturation in adolescent soccer players. In addition we investigated the other risk factor of the over-use injury during puberty.

Mothod: One hundred and twenty five well-trained adolescent soccer players aged 12.2±1.5 years old (9.5~14.8 years old) were participated in this study. Participants were divided into three age categories (U11, U13 and U15), four maturational difference (MD: skeletal age-chronological age) groups: Early (MD>1.0), Average (MD= ±1.0), Late (MD>1.0), and four height increment phase (HIP; Phase1 to Phase4) according to their annual height increment. Then relation between injury rate and these maturational statuses were examined.

Result: The rate of injury increases with age ($p<0.01$). In U15, late maturity players had the highest occurrence of overuse injury, while early-matured players tended to be vulnerable to acute traumatic injury. Moreover, players whose HIP was determined as phase2 (growth spurt) during the pre-season period had significantly higher rates of overuse injury than any other HIP group ($p<0.001$). In terms of acute injuries, players in Phase3 (after growth spurt) had the highest injury rate of all the HIP groups ($p<0.01$). During Phase2, players showed a rapid gain in height. Moreover, in Phase2, 56.9% to 91.7% of proximal tibial apophyses were determined as being in the apophyseal or epiphyseal stage of growth.

Discussion: These result may imply that relative stress forced by training becomes stronger for late matured players in older age group. Moreover, physical growth and apophyseal fragility are thought to be risk factors for soccer-related injuries. A player who's pre-season HIP is determined as Phase2 might be more vulnerable to overuse injury. Hence, we believe that evaluating individual pre-season HIP and biological maturity would help coaches and athletic trainers to predict and prevent certain kinds of soccer-related injuries.

CHANGES IN HCT AND HB IN RESPONSE TO HIT AND HVT

ZINNER, C., WAHL, P., HAEGELE, M., ACHTZEHN, S., DE MARÉES, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: Although there is a lively discussion about different physiological effects of high intensity training (HIT) vs. high volume training (HVT), the effects of these two types of training on blood profiles have been payed less attention. Numerous studies examined the response of blood profiles after short term maximal exercise or long-duration exercise, but to the best of our knowledge no study investigated the different response of blood profiles between these two interventions. Therefore the aim of the study was to compare the changes of hematocrit (Hct), haemoglobin (Hb) and plasma volume (PV) after a HIT session and a HVT session.

Methods: 8 male athletes (27.4 ± 6 years, 182.3 ± 8 cm, 75.6 ± 9 kg, 67.9 ± 4 ml/kg/min) performed two training sessions on a cycle ergometer. The HIT-session consisted of four 30 sec lasting maximal sprints with five minutes rest in between. During the recovery intervals, subjects remained in a sedentary position on the cycle ergometer. The HVT-session consisted of a 60 minute continuous trial at an intensity 41–45% of VO2max.

Both sessions started with a warming up of 10 minutes at an intensity of 1.5 Watt/kg bodyweight. Venous blood samples were taken before the warming up and ten minutes after the last sprint and after the 60th minute respectively.

Results: Hct values showed no significant differences before both sessions (43.0 ± 1.7 % vs. 42.7 ± 1.3 %). After the training Hct values were significantly increased after HIT (46.3 ± 1.7 %), but no significant changes were found after HVT (43.6 ± 1.7 %).

Significant changes in the Hb values were also found only after HIT (pre training 14.7 ± 0.6 g/dl vs. post training 15.5 ± 0.6 g/dl) (HVT: pre 14.7 ± 0.5 d/dl, post 15.0 ± 0.7 g/dl).

The percentage changes in PV were calculated from hematocrit and haemoglobin values (Dill, 1974). The increments of PV after the two interventions were significantly different (5.9 ± 1.9 % HIT and 1.8 ± 3.6 % HVT).

Discussion: The small shift of Hct, Hb and PV after HVT could be explained by the water loss during long duration exercise (sweat), but during the HIT session water loss due to sweat can be ruled out. The shift of PV, Hct and Hb after HIT was likely a result of an increased plasma osmotic pressure and local capillary hydrostatic pressure. During HVT sessions, hemodynamic forces are considerably lower than during the HIT sessions. For endurance athletes the WADA defined upper limits for Hct and Hb concentrations to reduce risk of blood manipulations. In this context focus lies on individual blood profiles to get individual Hct and Hb characteristics. Further studies should examine the effects of on PV, Hct and Hb during an interval of HIT and the shift over the time.

THE PREVALENCE OF METABOLIC SYNDROME IN JAPANESE STUDENT SUMO WRESTLERS

SAKAMOTO, S., MIDORIKAWA, T., OHTA, M., TORII, S., KONISHI, M., TAKAGI, S., BEMBEN, M.G., KONDOH, M.

1. WASEDA UNIVERSITY, 2. KANAZAWA SEIRYO UNIVERSITY, 3. UNIVERSITY OF OKLAHOMA, 4. NIHON UNIVERSITY

Purpose: The purpose of the present study was to investigate whether obese athletes, i.e., Sumo wrestlers, who are severely obese but have high physical activity levels suffer to metabolic syndrome.

Subjects: Subjects were 19 young Japanese student Sumo wrestlers. Their age was 19.5±0.8 years, body height 178.0±6.8cm, body weight 126.6±14.3kg, BMI 40.0±4.9kg/m2.

Methods: Sumo wrestlers underwent the following measurement (body composition including waist circumference, dual energy x-ray absorptiometry (DEX), MR imaging at abdomen, blood sampling at the fasting state in the early morning and blood pressure (BP)).These bloods were used for measurements of HDL-Cholesterol (HDL-C), triglyceride (TG), glucose and insulin level (IRI). Thereafter, the diagnosis of metabolic syndrome was made by the criteria proposed by the Japanese Society of Internal Medicine.

Results: Abnormally large waist circumferences (119.5±9.1cm) were present in all Sumo wrestlers. Eleven Sumo wrestlers (57.9%) had high blood pressure (systolic BP 125±23mmHg, 9 wrestlers≧130mmHg; diastolic BP 70±17mmHg, 4 wrestlers≧85 mmHg) and 6 wrestlers (31.6%) were categorized as dyslipidemia (HDL-C 44.4±8.7mg/dl, 5 wrestlers <40 mg/dl: TG 98.3±33.0mg/dl 1 wrestler≧150 mg/dl) as determined by the criteria. None of the Sumo wrestlers had fasting hyperglycemia (glucose 84.8±5.8mg/dl) for the criteria. The prevalence of metabolic syndrome in these Sumo wrestlers using the criteria was 4 wrestlers (21.1%), although about a half of the wrestlers (47.4%)had abnormal values for insulin resistance (IRI 13.6±6.5microIU/ml, 5 wrestlers≧15.0microIU/ml; HOMA-R 2.83±1.32 9 wrestlers≧2.5).

Discussion and Conclusion: The present study is the report that the prevalence of metabolic syndrome in young Japanese obese athletes (Sumo wrestlers) was 21.1% following the criteria determined by the Japanese Society of Internal Medicine. The Ministry of Health, Labour and Welfare in Japan reported that the prevalence of metabolic syndrome was 2.6% in Japanese males in their 20's, but there was no information how many obese men was included in the report. These results indicated that daily high intensity physical activity as demonstrated by Sumo wrestlers, does not reduce all risk factors for obesity, but the risk factors were somewhat attenuated as evidenced by the unexpectedly low incidence of metabolic syndrome. We think that it is necessary for us to continue further more investigation in this point of view.

DECREASED PERFORMANCE IN ATHLETES WITH PERIMESNTRUAL SYNDROMES

VAISBERG, M., BERENSTEIN, E., DI BELLA, Z.J., SCATENA, D.A., LOPES, A.C.

FEDERAL UNIVERSITY OF SÃO PAULO

Despite the great number of women performing sports there are only few studies about anatomical, psychological hormonal aspects that affect performance. A great part of these studies mention the relation between menstrual cycle and performance, but they don't

consider perimenstrual alterations. The prevalence of perimenstrual syndromes (PMS) in Brazil varies between 8 to 86%. These percentages enhance the importance of perimenstrual syndromes in the performance for competitive and non-competitive athletes. We studied thirty-one handball athletes, with normal menstrual cycles and non users of hormones. A questionnaire of pre-menstrual symptoms has been applied for three consecutive months and the diagnosis was made based upon the total score of six days preceeding menstruation, compared to the score of 5 to 10 days after menstruation. The diagnosis of perimenstrual syndrome was established when the athlete presented four or more symptoms, including one having to do with an altered mood. For the evaluation of resistance we compared the capacity to perform resistance exercises of the abdominal wall muscles and leg muscles. The prevalence of perimenstrual syndromes in our study was 71%. We analyzed our data in a cross-sectional and longitudinal study, finding that athletes with PMS were less capable to do resistance exercises during the pre-menstrual period compared to the post menstrual period, suggesting a decrease in performance. We were able to demonstrate that athletes evaluated in two different times showed a decrease in resistance of abdominal muscles (p< 0,01 and p< 0,01), leg muscles (p <0,01 e and p< 0,07) and arm muscles (p< 0,01 and p< 0,01), differences statistically significant. Asides the high prevalence of perimenstrual syndrome in the group of athletes we studied, we were able to demonstrate in this group a decrease performance in athletes performing resistance exercises during pre-menstrual period.

CAROTID FLOW VOLUME IN EVALUATING EXERCISE CAPACITY

Introductions

Echocardiography is the basic and non-invasive method in assessment of heart's structure and function in elite athletes, so it is sometimes used for medical check and studying in some special sports. In men, it has been studied that prediction of the peak oxygen consumption with evaluation of the cardiac output at rest or diameter of the left ventricular at the end diastolic phase by echocardiography. In this study, we examined carotid blood flow and cardiac output, and we also studied peak oxygen consumption (VO2), then we evaluate the relationship between carotid blood flow or cardiac output and peak oxygen consumption.

Methods: For 23 well general female college students, we examined wall- thickness (LVPWd: left ventricular posterior wall diameter), IVSd (Inter-ventricular septal end diameter) at the end of diastolic phase, a cardiac output (CO) and carotid flow volume (FV) by ultrasonography. We also examined peak VO2 using breath by breath analyzer by gradual increasing work load with treadmill running.

Results: Peak VO2 was 47.07 (SD: 0.67) ml/kg/min, and was significantｌｙ correlated with IVSd, LVPWd and CO. In addition, cervical artery flow volume was also significantly correlated with peak VO2.

Discussion: In the previous study of men, athletes compared to normal controls, LVPWd and IVSd were significantly larger and LVPWd or IVSd could be used for evaluating training effects. In this female study, we suggests that FV can be used for evaluating training status or level besides IVSd, LVPWd and CO.

EFFECTS OF AEROBIC EXERCISE INTENSITY ON CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH METABOLIC SYNDROME

KANG, S.J., KIM, B.R., KIM, J.H., LEE, D.K., OAK, J.S.

1. CHANGWON UNIV., 2. INJE UNIV., 3. SEOUL NATIONAL UNIV. OF EDUCATION, 4. DANKOOK UNIV.

The purpose of this study was to investigate the effects of aerobic exercise intensity on cardiovascular risk factors in patients with metabolic syndrome. The subjects were middle-aged women. Promotion Center of the C city. The subjects were randomly divided into the following three groups: moderate-intensity group(n=9, 40-60% of the heart-rate-reserve(HRR) method), high-intensity group(n=9, 60-80% of the HRR), and control group (n=8). The exercise groups were invited to participate in an exercise program consisting of a motor-driven treadmill walking and/or running for 12 weeks with frequency of 5 times per week, while the control group remained in normal lifestyles but refraining from any type of regular exercise.

The Fasting glucose were significantly decreased than those after treatment in both moderate and high-intensity exercise groups before treatment whereas the control group showed no difference. However, no significantly difference between moderate and high intensity exercise groups.

The Total cholesterol and LDL-C levels were significantly decreased than those after treatment in both moderate and high-intensity exercise groups before treatment. The HDL-C levels were increased in both moderate and high-intensity exercise groups after the treatment. The triglyceride levels were no difference among the group, but the triglyceride was decrease after treatment then before treatment. However, no significantly difference between moderate and high intensity exercise groups.

The Insulin and Insulin resistance were significantly decreased than those after treatment in both moderate and high-intensity exercise groups after treatment.

The Renin-angiotensin Ⅱ levels were significantly decreased than those after treatment in both moderate and high-intensity exercise groups before treatment.

The C-reactive protein were significantly decreased than those after treatment in both moderate and high-intensity exercise groups before the treatment.

Consequently, the moderate and high-intensity aerobic exercise during 12 weeks effect positively on cardiovascular risk factors such as obesity, hypertension, diabetes, hyperlipidemia, insulin resistance, inhibition of renin-angiotensin Ⅱ activation and decrease of C-reactive protein of patients with metabolic syndrome.

DEVELOPMENT OF A TEST BATTERY FOR THE SOCCER GOALKEEPER

KNOOP, M., PISCHETSRIEDER, H., LANGE, P., FERRAUTI, A.

RUHR UNIVERSITÄT BOCHUM

Up to now regular performance diagnostics in professional and upper-league amateur soccer have only dealt with the requirement profiles of outfield players. The goalkeeper´s special workload demands in competition and training have not been given enough attention. In order to close this gap we began to develop a specific test battery focused on the offensive and defensive requirements of the goalkeeper in the modern game. Therefore, in accordance to a systematic analysis of all goalkeeper activities during the European Championships 2008, we designed the following tests:

- Elementary ability tests: Squat Jump (SJ), Counter-Movement-Jump (CMJ), Foot Tapping (FT)
- Complex offensive ability tests: precision and speed of passes, throws and kicks
- Complex defensive ability tests: 5 and 10 m sprint, sidestep sprint (SS), reaction and action velocity (RAV) and safe hands (SH).

RAV is measured by a self developed measurement system, the "Keepers Time Detector" (KTD 4pro), consisting of a fourfold selected optical signal and four respective defense actions to a fixed and contact sensitive ball (top right, top left, bottom right, bottom left of the goal). We analyze time and split time for singular or multiple defense actions. SH was measured using a ball cannon and a protocol with a stepwise increasing ball velocity.

The test battery was applied with seven 1st division teams ("Junioren Bundesliga"). Sixteen junior goal keepers (18.0±0.9 yrs; 187±5 cm; 80.4±7.7 kg) participated in the study. Selected results (mean values, standard deviation) are presented: SJ height (39.4±4.4 cm); CMJ height (47.5±5.8 cm); FT (11.4±1.1 Hz); throwing distance (39.2±3.3 m); speed of kicks (109.9±5.0 km/h); 5 m sprint (1.11±0.05 s) and 10 m sprint (1.87s±0.05 s). Singular RAV in different directions did not correlate very closely, neither to the top left and right angles of the goal (left 1.41±0.07 s vs. right 1.39±0.06 s; r=0.5), nor to the bottom left and right angles (left 1.30±0.05 s vs. right 1.23±0.07 s).

The individual results are compared to the collected mean values and specific training recommendations are given to the coaches. Specific differences in the reaction and action velocity (RAV) to the left vs. right or to the top vs. bottom angles, respectively, are analyzed individually. Further detailed analysis of movement processes (footwork, step-sequences, upper body work) are planned focusing on an increasing efficiency of motor solution.

PHYSICAL AND PHYSİOLOGICAL PROFİLE OF ELİTE SOCCER REFREES IN PRE PREPERATİON AT HIGH ALTITUDE

KIZILET, A., KIZILET, T., TOPSAKAL, N., ORTA, L.

MARMARA UNIVERSITY

BACKGROUND: The purpose of this study was to examine the relationship between maximal aerobic power and fatique index in elitee soccer referees and assistant referees. The second purpose of this study was to examine the relationship between after multistage Shuttle run test's actıve recovery heart rate, blood lactate level with maximal aerobic power and fatique index in elitee soccer referees and assistant referees.

METHOD: 5 top class and 25 elitee soccer male referees mean age 33,47 ±4,76, height 178,83 ±3,80 cm, weight 79,25.±5,60 kg., body mass index 23,46 ±1,99, % body fat 14.8 ± 2,35; and 7 top class and 44 elitee male assistant referees mean age 29,76 ±3,64, height 178,13 ±4,78 cm, weight 74,82 ±6,11 kg., body mass 21,03 ± 1,48, body fat 15,02 ±2,47 gr. took part in the study. Maximal oxygen uptake (maxVo2) during Multistage Shuttle run test and fatique index during 6x40 metre repeated-sprint performance test were measured in the soccer field. All tests were performed higher than 1500 metres altitude before preperatıon term. Blood lactate were measured by Roche, Micro Volume Lactate Analyser. Significant correlations were examined via Pearson product correlation coefficients.

RESULTS: Elite referees demonstrated a mean aerobic power of 46,23 ±3,03 ml.kg-1/ min-1. Mean final heart rate, after 1 min, 2 min and 3 min resting heart rate were 179±9, 141±12, 118±9, 108±8 b.min¬¹, respectively. After multistage shuttle run testing blood lactate level were 7,84±1,97 mmol l (-1), mean fatique index were 0,25 ± 0,13 s. and mean sprint time were 5,96 ± 0.21 s. Assistant referees demonstrated a mean aerobic power of 46,83 ±2,93 ml.kg-1/ min-1. Mean final heart rate, after 1 min, 2 min and 3 min resting heart rate were 180±10, 139±13, 119±10, 110±9 b.min¬¹, respectively. After multistage shuttle run testing blood lactate level were 7,64 ±1,95 mmol l(-1), mean fatique index were 0,62 ±0,43 s. and mean sprint time were 6,19 ±0.24 s. No significant correlations were established between maximal oxygen uptake and the fatique index (r= -125 and -042, p>0.05) in referees and assistant referees. There was no significant correlation between active recovery heart rate, blood lactate level with maxVo2 and fatique index in referees and assistant referees. There were just significant negative correlation between maxVo2 and blood lactate concentration in elite assistant referees (r= -,424 p<0.05).

CONCLUSIONS: Tests were performed before pre-sessıon and hıgh altitude, because of thıs will be expected to affect negative on maxımal aerobic power and fatıque index variables. İmproved of maximal aerobic power might reduce the negative effect on blood lactate accumulatıon.

COMPARATION BETWEEN SOCCER PLAYERS IN FUNDAMENTAL SKILL FROM DIFFERENT POSITION.

CAMPOS, P., JUNIOR, A.F.

UNAERP UNIVERSIDADE DE RIBEIRAO PRETO

Introduction: The athletes' performance and accuracy from the basics movements it may interfere on the match results, using the premises that the team with the best average in the fundamentals has the best probability of a positive result. The purpose of this study was to evaluate and compare four basics soccer fundamentals in a group of soccer players who plays in a different position.

Methodology: The experimental group of 20 Brazilian male soccer player (mean age 16,3) were tested throughout a 4 basic soccer fundamental in a field test. The fundamentals tested were accuracy shooting, accuracy pass, conducting the ball and penetration throughout obstacles without the ball and with the ball. Group 1 consisted of four fullbacks, group 2 four halfbacks, group 3 four wings, group 4 four midfield and group 5 four forward. Accuracy shooting: consisted of an unobstructed divided goal in 6 quadrants target with different punctuation. The participants were asked to take four shots from a set distance away in 15 seconds. Accuracy pass over a short distance: This test is handicapped by the amount of time a subject has to complete the course. The test was designed so that each pass should be done with alternative feet, left right, left right or visa versa. A participant must score maximum accuracy points before time. Penetration throughout obstacles without the ball and with the ball: this test was designed to improve close control while at pace without and with the ball. Eight cones are set out in a slalom effect and a single cone is placed a set distance. The idea was for the subject to run the slalom course up and down, with(out) the ball at his feet to the other designated cone.

Results: Observed differences occurred during the Penetration throughout obstacles without the ball were: the wings (mean 7,4 ±0,7 m/s); the fullbacks (7,2 ± 0,2 m/s); the halfbacks (7,5 ± 0,9 m/s); midfielders (7,4 ± 0,6 m/s); and (7,1 ± 0,7 m/s) for the forwards. No significant difference were found between the groups $p<0,05$. Penetration throughout obstacles with the ball the mean were for: the wings (11,4 ± 1,9 m/s) ; fullbacks (10,9 ± 1,4 m/s); halfbacks (10,9 ± 1,3 m/s); midfield (9,9 ± 1,6 m/s) and (9,3 ± 2,3 m/s) for the forwards. A significant difference were found t student $p<0,05$ between the wings players and forwards.

Conclusion: the forwards players appear to posses a better speed in the penetration run throughout obstacles with the ball among the others groups. This could be especially important because the speed and the fundamentals skills based on the level of the game and the player can make the difference during the match.

THE ROLE OF FATIGUE DURING THE PHASES OF THE VERTICAL JUMP IN YOUNG FOOTBALL PLAYERS

SANNICANDRO, I., PETITO, A., ROSA ROSA, A., PICCINNO, A., DE PASCALIS, S.

UNIVERSITY OF FOGGIA, 2SSIS PUGLIA (SUPERVISOR SCHOOL OF SECONDARY SCHOOL TEACHER TRAINING)

Introduction: The analysis of the vertical jump phases becomes relevant in consideration of the epidemiological data of non-contact muscular and joint traumas. Such data have shown that non-contact traumas in team sports constitute 39% of injuries in female basketball and 14% of injuries in men's football (Junge et al., 2006) Thus, the assessment of the vertical jump is not only a control indicator of performance and efficiency of the neuromuscular system of athletes, but it can also be analysed from the qualitative point of view.

The aim of the study was to investigate the influence of fatigue upon various phases of the vertical jump after a maximal aerobic power test.

Methods: The sample was formed of n=15 young professional football players (mean±SD age, height and weight: 13.7±0.4 years, 166.1±6.1 cm, 58.7±4.7 Kg respectively).

The Counter Movement Jump (CMJ) was used to evaluate vertical jump phases by means of two different dynamometric platforms, one for each limb (Twin Plates and Globus Italia), equipped with specific software for the analysis of the movement. The evaluation of the jump was carried out before and immediately after the execution of an incremental shuttle run test (Léger & Cazorla, 1993). Statistical analysis was carried out using the non-parametric Wilcoxon signed-rank test with $p<0.05$ considered as significant.

Results: The mean values showed a significant decrease in the height of the vertical jump (-12,1%, $p<0.001$), an significant increase in the overstretching time phase, that is, the eccentric loading phase ($p<0.001$) following the performance of an incremental shuttle run; a temporal increase was observed in the isometric stabilization phase when the subject terminates the jump after landing, but statistics did not find the change to be significant.

The mean value of maximal aerobic velocity reached by the sample in the Léger test was 13.0±0.5 km/h; equal to a VO2 max of 57,0 ml/kg/min.

Discussion: During the vertical jump, the athlete reproduces all the patterns of neuromuscular activation that can be found during characteristic sports movements, like breaking, cutting, acceleration and landing after the execution of a jump (Sannicandro, 2008).

The analysis of some phases of the jump demonstrate the considerable influence that fatigue has upon the ability of the athlete to elevate the body and, above all, upon the duration of the extremely important phase of pushing.

Alterations to the usual execution pattern of the jumping movement and, in particular, to the eccentric phase of the jump, could be put compared to slight decreases in postural control and consequently represent a potential risk of joint injury in the lower limbs.

RELATIVE CHANGES IN BODY COMPOSITION AND FUNCTIONAL CAPACITIES IN REGIONAL YOUTH SOCCER PLAYERS 10 - 16 YEARS

VÄNTTINEN, T.

RESEARCH INSTITUTE FOR OLYMPIC SPORTS

Introduction. In general, the changes in body composition and functional capacities that occur with chronological age during puberty in males is well documented (Malina 2004). In addition, Philippaerts & al. (2006) have shown that the peak development in functional

capacities occurs around at time of peak height velocity among youth soccer players. Even though the peak height velocity is obviously independent from exact chronological age, the Finnish junior soccer teams are organized based on chronological age. Therefore, the aim of this study was to examine in which chronological age group the peak development of different body composition variables and functional capacities occurs.

Methods. Three age groups (10y, 12y and 14y) of the regional club team (n = 12-14 players/team) representing area of around 160 000 habitants were followed two years in terms of body composition (height, weight; standard techniques, muscle mass; bioimpedance Inbody 720), hormonal status (testosterone; basal venous sample after 12 h fasting), speed (30 m; light cells), agility (8-track; light cells), explosive strength (CMJ; contact mat, 5-step; standard technique), isometric strength (legs 107°, abdominals, back; dynamometer) and soccer skills (passing and dribbling; skill tracks). Thus, in the present set-up age groups from 10y to 16y were covered so that the same players were followed from 10y to 12y, from 12y to 14y and from 14y to 16y.

Results. The relative peak development in measured variable occurred between 10y to 11y in soccer skills (8.4 ± 2.6 %); between 12y to 13y in length (5.0 ± 1.7 %), weight (14.1 ± 4.6 %), muscle mass (15.2 ± 7.9 %), speed (5.2 ± 3.8 %) and agility (3.8 ± 2.6 %); between 13y to 14y in hormonal status (5.8 ± 5.5 nmol/l), CMJ (13.5 ± 10.4 %) and leg strength (24.1 ± 28.4 %); between 14y to 15y in 5-step (8.1 ± 4.2 %), abdominal strength (26 ± 16.5 %) and back strength (17.7 ± 12.7 %). No peak development was found between 11y to 12y or between 15y to 16y in any measured variables.

Conclusions. The results of the present study suggested that the peak development during puberty in Finnish regional soccer players occurred first in the basic soccer skills followed by the changes in body composition and speed related tasks and finally in the explosive and maximal strength. From the results of the present study it can be recommended that the soccer training should focus on exercises which develop speed and basic soccer skills in early puberty. At the age of 14 years the players are ready to begin strength training and are hormonally more ready for "adult-like soccer training".

OBSERVATIONAL METHODOLOGY IN FOOTBALL: DEVELOPMENT OF AN INSTRUMENT TO STUDY GOALKEEPER BEHAVIOR IN THE DEFENSIVE PROCESS – SOFGR1.

SARMENTO, H., ESTEVES, A., MARTINS, N., OLIVEIRA, C., LEITÃO, J., ANGUERA, T., CAMPANIÇO, J.

UTAD; UNIVERSITY OF BARCELONA

Traditional methods for quantifying sport performances (e.g., frequency of actions) are limited in their ability to describe the interaction of events that occur over time (Borrie et al., 2002). The aim of our study was to develop an innovative instrument for observation that can strengthen the existing schemes of game analysis in football in order to provide specific additional information on the behavior of Goalkeepers (GK) during the Defensive Process (DP).

The observational design of this study is located in quadrant IV, i.e. it has got a Follow-up design/Nomothetic/multidimensional (Anguera et al., 2000). The observational instrument is formed by a combination of field format and systems of categories. Our research focused on binomial Finalization/GK or attempted Finalization/GK, and investigated what precedes the finalization and what happens to the completion of the GK intervention.

The games were recorded on VHS video and then converted to MPEG-1. Our decision in relation to the observational sample took into account the establishment of 2 sampling levels (intersessional and intrasessional), from which a series of measures were taken. After a series of experimental observational sessions to test the observational instrument and to train the observers, we analyzed the quality of data through the intra-observer agreement (verified by the Kappa index of reliability of Cohen). The comparison of data recorded during the observational period was done using the SDIS-GSEQ program and its function for "calculating the Kappa coefficient".

The resultant observational instrument 'ad hoc' was created according to four criteria: i) guiding the offensive process; ii) offensive end of the process; iii) GK in the defensive process; and iv) effectiveness of the GK in the defensive process. The instrument of codification was sufficiently discriminatory; therefore fulfilling the requirements for the purpose it was created. It also demonstrated to be highly reliable, seen by the high correlation values (over 97,5 % for all criteria), and therefore opening the possibility for more objectives studies.

This instrument may be improved in the future by adapting it to the specific aims of the investigation and knowing that one can add or delete criteria, or simply focus on specific aspects of interest in studying certain football match periods.

A COMPARISON OF PHYSIOLOGICAL PARAMETERS BETWEEN FOOTBALL PLAYERS AND RUNNERS COMPETING IN VARIOUS RUNNING EVENTS

VUCETIC, V., PUCEK, M., SENTIJA, D.

FACULTY OF KINESIOLGY UNIVERSITY OF ZAGREB, CROATIA

Introduction: Which type of endurance is crucial in modern football - aerobic or anaerobic? Over the last 20 years football has evolved, especially in terms of athletic preparation of the players, to answer demands of higher intensity of the game and longer field distances covered by players. All those changes require specific training methods and corresponding physiological adaptations of the players. Trained runners, competing in different running events, may serve as role models through the whole range of endurance capacities, from purely anaerobic to ultra-distance aerobic endurance. Therefore, the primary purpose of this study was to compare football players with runners, in parameters of an all-out incremental treadmill test with gas exchange measurements: peak oxygen uptake (VO2max), maximal heart rate (HRmax), maximal running speed achieved in the test (vmax), and speed (vAT) and heart rate (HRAT) at the anaerobic threshold.

Methods: Forty-eight national level male runners, competing in running events with predominantly aerobic (AE: 23 middle and long distance runners, 179.6±6.2 cm, 69.1±6.5 kg) or anaerobic (AN: 25 sprinters and 400m runners, 182.5±4.8 cm, 74.5±5.8 kg) metabolic demands, and 45 national/international level football players: 15 defenders (D, 184.4±5.7cm, 77.2±17.7kg); 15 midfielders (M, 179.7±7.0 cm, 76.1±6.8 kg) and 15 forwards (F, 180.9±6.0 cm, 77.7±8.3 kg) participated in the study. All subjects performed an

incremental treadmill test to exhaustion (speed increase 0.5 km/h every 30 s, 1.5% grade). ANOVA was used to determine differences in observed variables between the groups.

Results: As expected, VO2max was significantly higher in AE runners (66.4±4.4 ml/kg/min) than AN runners (58.0±4.1 ml/kg/min, $p<0.05$), whose values were similar to those in football players (D: 56.4±4.6 ml/kg/min; M: 57.2±5.1 ml/kg/min and F: 57.0±4.5 ml/kg/min). The HRmax differed significantly between AE and AN runners (191±9 : 198±7 bpm, $p<0.05$), while no difference was present between football players of various playing positions (D : M : F – 192±10 : 193±6 : 193±9 bpm). The AE runners had significantly higher values of vmax and vAT (21.5±1.2 and 16.7±1.5 km/h) than the AN (18.5±1.5 and 13.2±1.2 km/h)($p<0.05$). The values of vmax and vAT in football players (D: 18.5±1.1 and 13.6±0.6 km/h; M: 18.8 and 13.8±0.7 km/h; F: 19.3±1.5 and 13.9±0.9 km/h) were similar to the values of AN runners ($p>0.05$), and hence also significantly lower than in AE runners.

Conclusion

The results of this study indicate that, when comparing physiological parameters from an all-out incremental treadmill test between football players and trained runners, the values of football players approximate most closely those of the 400 m runners. This singles out the possible importance of the anaerobic capacity and a high level of sprint endurance in football players.

IS THE FUNCTIONAL CAPACITY CRUTIAL FOR POSITION DETERMINATION IN THE FOOTBALL TEAM?

VUCETIC, V., SUKRESKI, M.

FACULTY OF KINESIOLGY UNIVERSITY OF ZAGREB, CROATIA

Introduction: During past twenty years, many new elements introduced in the football game have significant changed the way it is played. There are many differences between the old type of playing football and today's modern view of football but the two most important are speed of the game and the game's dynamic. This is why significance of conditional component in football training is very important. Guided with this thought, we have asked ourselves if there are any differences in the functional capacity between defenders, middle field players and attackers.

Methods: Forty five football players (24.1±4.4 yrs; 182± 6.2 cm; 79.9 ± 7.5 kg) were divided in three groups: 15-defenders (DEF), 15-middle field players (MF) and 15-attackers (AT). Football players in this research were taken from the National team and the first Croatian football league. All subjects performed an incremental treadmill test (0.5 km/h speed increase per half minute, 1.5% grade) to volitional exhaustion, and walked at 5 km•h-1 during the first two minutes of recovery. The ANOVA was used to determine differences in observed variables between the groups.

Results: As expected, analysis showed no significant difference between players in basic morphological variables according playing position (DEF-184.9±5.8 cm and 83.6±7.5kg; MF=180.3±6.3 cm and 78.4±5.7 kg; AT=180.9±6.0 cm and 77.9±8.2 kg). In the same time, significant difference we didn't find in parameters of maximal heart rate (DEF=190.5±12.9 bpm, MF=190.5±7.3 bpm and AT=191.0±8.1 bpm), heart rate on the anaerobic threshold (DEF=149.0±11.7 bpm, MF=169.7±7.9 bpm and AT=170.5±8.8 bpm), maximal relative oxygen uptake (DEF=57.1±4.7 ml/kg/min, MF=56.6±3.4 ml/kg/min and AT=57.1±4.6 ml/kg/min) and relative oxygen uptake on the anaerobic threshold (DEF=48.8±4.4 ml/kg/min, MF=55.6±30.4 ml/kg/min and AT=48.7±3.7 ml/kg/min). Looking at research in general, such results we can ascribe last trends in modern football which from each player requirements equal energetic demand.

Conclusion: There are differences between defenders, middle field players and attackers, but they are not significant. Such results are consequence of requirements that modern football demands from football players. In modern football, each player participates in all phases of the game. So, we can say that the old style of playing football, that divides team into two main groups, defenders and attackers, is history.

EVALUATION OF BODY COMPOSITION, MUSCLE STRENGTH AND BALANCE IN ADOLESCENTS SOCCER PLAYERS

ERKUT ATILGAN, O., SIRMEN, B., UZUN, S., RAMAZANOGLU, N., AKAN, İ., ATIL, Z.

MARMARA UNIVERSITY

Purpose: Soccer requires high leg strength, fit body composition and good postural control especially unipedal posture. In this research, we aim to investigate whether there are relationship between strength (muscle strength and muscle lean mass) and balance (static and dynamic) in soccer players.

Materials and Methods: 17 soccer players (mean: age=15 height=168,5 weight=65,5 BMI=20,8 training years=4,6) were participated in the study. Legs strength was measured with leg dynamometer; body composition was measured x-scan body composition analyzer.

Balance (static and dynamic) was measured Prokin 5.0 Technobody. Static stabilometery tests were done as Opened Eyes (EO) and Closed Eyes (EC) with 30 second duration. Dynamic Stabilometery Tests: a) Slalom test (forward-backward) to one axis a time. The subject's scope is to hit objectives and follow the blue ideal line within 60 sn duration (a-hold with two hand and b-without hold) with 5 hard degree. b) Unilateral dynamic-stance tests (left and right leg) was done with the controlled load monoaxial test (antero-posterior) for right and left foot with 10 repetitions on an axis controlling player's load (5 hard).

Results: Correlation was done between strength (muscle strength and muscle lean mass) and balance (static and dynamic) in soccer players. There were significant relationship Static Romberg Test EC/EO Perimeter Ratio and Left leg, right leg, trunk lean mass. No significant correlations were found between dynamic tests and body composition.

There are high negative correlation between lean mass percent and fat percent of soccer players. Thus; this players have enough fit condition for their branches. Besides, there are high correlations among leg strength and legs (left and right), trunk lean mass.

Left and right leg lean mass, left and right leg perimeter error scores for anterior-posterior dynamic balance were compared with paired samples T-test. Left lean mass is better than right lean mass ($p<0.05$), similarly, left leg dynamic balance was greater than right leg dynamic balance ($p<0.01$).

Conclisions: As a result, increases back and leg muscle lean mass and strength is associated with better postural stability, there should be further research for the balance evaluations after the strength training program for different sports.

TAKING INITIATIVE IN SMALL-SIDED SOCCER GAMES

FRENCKEN, W., OTTEN, E., VAN DER PLAATS, J., VISSCHER, C., LEMMINK, K.

UNIVERSITY MEDICAL CENTER GRONINGEN, UNIVERSITY OF GRONINGEN

Introduction: In many sports, players interact during a game. Dynamical systems theory provides tools to investigate these interactions by assessing phase relations. It has been suggested that a squash player with a lead phase relation has an advantage over the player with the lag phase relation with respect to rally outcome (McGarry et al., 2002). Therefore, phase delay between players might be a tool to investigate dominance during rally's in racket sports (Palut & Zanone, 2005). It can be hypothesized that in ball team sports like soccer, a lead phase relation of the attacker increases the chance to score. Therefore, the aim was to investigate initiative in attacker-defender dyads in small-sided soccer games

Methods: Ten young male elite soccer players (17.3 years ± 0.7) participated in three small-sided soccer games (4-a-side plus goalkeepers) of 8 minutes on a 28x36m pitch. Player positions were recorded at 45Hz per player by means of innovative technology, i.e. local position measurement (LPM) system. Cross-correlations and delays were calculated for acceleration profiles of all players 25Hz over a sliding 2,5s interval (NBody software, UMCG Groningen). To exclude less relevant couplings between players, a cross-correlation coefficient of 0.4 was set as threshold value. Only couplings between the attacker and defender prior to a goal or goal-scoring opportunity were included in the analysis. The attacker was the player that attempted to score, whereas the defender was the opponent of that particular attacker. All couplings were investigated through visual inspection.

Results: In total, 66 goal-scoring opportunities were notated of which 19 resulted in a goal. Preliminary results show that for 65% of the goals and goals-scoring opportunities the attacker holds initiative, with no difference between goals and goals-scoring opportunities. In addition, we found that the percentage of the attacker's initiative decreases with type of attack (100%, 85%, 55% and 33% for 1v1 situations, regular attacks, counter attacks and long distance shots respectively).

Discussion: Results indicate that attackers most frequently take initiative prior to goal-scoring opportunities. The absence of clear differences between goals and goal-scoring opportunities indicates that whether or not a goal is scored eventually, depends on other factors, e.g. technical ability, goalkeepers ability and luck. The trend we found for the attacker's initiative for the different types of attack is in line with the task of the attacker in the various types of attack. In 1v1 situations, the attacker has to take initiative, whereas that is less required in long distance shots. Based on this study, it can be concluded that encouraging attackers to take initiative increases the chance to score and therefore to win the game.

EFFECTS OF OFFICIAL YOUTH TAEKWONDO COMPETITIONS ON ALL-OUT PERFORMANCES OF ATHLETES

CHIODO, S., TESSITORE, A., CORTIS, C., LUPO, C., AMMENDOLIA, A., IONA, T., CAPRANICA, L.

SCHOOL OF MEDICINE, UNIVERSITY OF MAGNA GRAECIA, CATANZARO, ITALY

Olympic Taekwondo is a very popular sport, considered appropriate for children also to educate their discipline, control, and respect (Yard et al., 2007). Although athletes start training and competing around 10 years of age, no information is provided on the demands of the youth competitions. In fact, research on youth Taekwondo focused mainly on injury (Beis et al., 2001; Yard et al., 2007; Shin et al., 2008) and the physiological profile of young athletes (Melhim, 2001), while heart rate and blood lactate responses to simulated (Bouhlel et al., 2006; Butios & Tasika, 2007) and official (Chiodo et al., 2008). Taekwondo competitions have been reported only on elite athletes. The unique chance of cooperation with the Italian Teakwondo Federation (FITA) presented us with an opportunity to have access to physiological and performance measurements on young athletes during the Italian Youth (i.e., Cadetti A) Taekwondo Championship. Therefore, the aim of the present study was to evaluate the cardiac load of youth Taekwondo matches, and the differences in the athletes all-out performances (countermovement jump and handgrip) assessed before and at the end of their competition.

Seven female and eleven male young (range 13-14 yrs) Taekwondo athletes participated in the study. During Taekwondo competitions mean heart rate (HR) was 187±11 beat.min-1, with no difference between rounds and gender. HR higher than 85%HRmax showed a 77±27% frequency of occurrence. A difference ($P<0.05$) for gender (females: 22±2 cm; males 27±6 cm) and its interaction with session was found for jump performances. Post hoc analysis showed no difference for female athletes while better performances after the match (28±6 cm) than those recorded before the match (25±6 cm) emerged for male athletes. Peak handgrip values were always found for the right limb ($P<0.001$), with differences ($P<0.01$) for gender and session. Lower grip strength values were observed after the match (females: 272±58 N; males: 297±67 N) with respect to pre-match values (females: 256±54 N; males: 275±64 N).

The findings showed that Taekwondo competition is a high intensity intermittent activity. It could be speculated that the repeated concussions on the upper limbs used to protect from the opponent's kicks and punches directed toward the scoring area of the torso might be responsible for the decrease in grip strength at the end of the match. The gender differences observed for jump performances at the end of match encourage further research in this area.

TECHNIQUE AND BALANCE IN ELITE JUDO

RODRÍGUEZ-ROMO, G., STIRLING, J., ZAKYNTHINAKI, M., LÓPEZ DÍAZ DE DURANA, A., CORDENTE MARTÍNEZ, C., SILLERO QUINTANA, M., SAMPEDRO MOLINUEVO, J.

TECHNICAL UNIVERSITY OF MADRID (UPM)

Introduction: Balance is fundamental in judo, both in attack when trying to break the opponent's balance and in the defense of such attacks. Tools from dynamical systems have recently been used to model the process of regaining balance following a perturbation form quiet stance (Zakynthinaki et al, 2008; Stirling and Zakynthinaki, 2004). The aim of this study was to apply the model of Stirling and Zakynthinaki (2004) to look at the connection between the balance of elite judokas and their technique both in attack and defense.

Methods: 5 judokas of the Spanish National Team were studied. The ground reaction forces resulting from the judoka being perturbed from quiet upright stance, for the two legged and single legged condition (Zakynthinaki et al, 2008; Stirling et al, 2007) were modeled and analyzed. With the use of a force platform the maximum correctable angles between the resultant ground reaction forces and the vertical in the anteroposterior and mediolateral directions were obtained. A closed critical curve (Stirling and Zakynthinaki, 2004) was then fit through the maximum correctable angles (for greater angles than these the judoka falls over). The curve was analyzed to find asymmetries. Each judoka also completed a questionnaire regarding their preferred techniques, with video being taken both of these techniques and also all the experiments.

Results: It was observed that the favored side (in the case of the two legged experiment) or leg (in the case of one legged experiment) for balance was connected with technical features of the preferred techniques of the judokas. In some of the judokas this preference was shown to be strong.

Discussion: Non-symmetric behavior caused by muscle imbalances, postural problems, structural problems and differences in the ranges of motion on either side of the body have been identified via the critical curve (Zakynthinaki et al, 2008; Stirling and Zakynthinaki, 2004). Our research has shown how these methods can be used to identify competitive strengths and weaknesses for addressing and correcting via training in elite judo (Stirling and Zakynthinaki, 2005; A. López Díaz de Durana, 2009).

BALANCE IN ELITE JUDO AND ITS RELATIONSHIP WITH INJURIES

LOPEZ DIAZ DE DURANA, A., STIRLING, J.R., ZAKYNTHINAKI, M.S., RODRÍGUEZ-ROMO, G., CORDENTE MARTINEZ, C., SILLERO QUINTANA, M., SAMPEDRO MOLINUEVO, J., REFOYO, I.

TECHNICAL UNIVERSITY OF MADRID

Introduction: Balance and posture in general is often affected by the history of injuries: different injuries affecting the balance or movement pattern of the individual in different ways. The converse of this is also true, in as much as irregularities in an individual's posture and balance can increase the likelihood of particular injuries. The aim of this study was to apply the model Stirling and Zakynthinaki (2004) and the tools presented in Zakynthinaki et al (2008) to examine the connection between injuries and the asymmetries in the balance of elite judokas.

Methods: 5 elite judokas took part in the study. Each judoka stood on a force platform and was perturbed from quiet upright stance, for the two legged and single legged position (Zakynthinaki et al, 2008; Stirling et al, 2007). The maximum correctable angles between the resultant ground reaction forces and the vertical in both the anteroposterior and mediolateral directions were obtained. A closed critical curve (Stirling and Zakynthinaki, 2004) was fit through the maximum correctable angles at which the judoka could lean. This critical curve was analyzed for asymmetries and the judokas completed a questionnaire regarding their history of injuries. Video was also taken of all the experiments in both the anteroposterior and mediolateral directions so as to allow us to observe some of the basic irregularities in the posture and movement patterns.

Results: A connection between the asymmetries in the critical curve and both the history of injuries and the current injuries was observed. In particular very strong asymmetries in the critical curve were shown to exist for those judokas who were injured when they completed the test.

Discussion: Injuries can result in muscle imbalances, postural problems, structural problems and hence as a result can cause asymmetric movement patterns which lead to differences in the ranges of motion on either side of the body. Such differences have been identified via the critical curve (Zakynthinaki et al, 2008; Stirling and Zakynthinaki, 2004). Our research has shown how these methods can be used to identify both current injuries and those which have occurred in the past (Stirling and Zakynthinaki, 2005).

AN INTRACELLULAR WATER REDUCTION BEFORE A COMPETITION DECREASES GRIP STRENGTH IN ELITE JUDO ATHLETES

SILVA, A.M., MATIAS, C., QUITÉRIO, A., OLIVEIRA, S., SANTOS, D., SARDINHA, L.B.

FACULTY OF HUMAN KINETICS

PURPOSE: To analyze the effect of body composition changes, from a period of weight maintenance to before a competition, on forearm maximal strength in male judo athletes. METHODS: A total of 26 men, top-level athletes (age: 23.2±2.9 yrs), were evaluated at baseline (weight. 73.1±7.1 kg; percent fat mass (%FM): 12.2±3.1 %) and 1-2 days before a competition (Weight: 72.0±7.0 kg; %FM: 11.7±2.8 %), with approximately 1 month apart between moments. Before the competition some of these athletes lost weight through self-determined means while others remained or increased their weight. A 7-day recall of dietary food intake was recorded at baseline and before the competition. At both moments, and after an overnight fasting, total body water (TBW), extracellular (ECW), and intracellular water (ICW) were estimated by bioelectrical impedance spectroscopy while FM, fat-free mass (FFM), lean soft tissue (LST), and arms LST were assessed by dual-energy x-ray absoptiometry (DXA). At baseline and at before a competition, a handgrip was used to assess forearm maximal strength (FMS) of the dominant arm. Changes are expressed as a percentage of the baseline value; comparisons of means, bivariate and partial correlations were used. RESULTS: A significant mean reduction ($p<0.05$) in weight [-1.4±2.4 %, -6.2 to 2.8 % (mean ± SD, range)] and FM (-4.6±9.6 %, -21.9 to 14.0 %) was observed while no significant mean changes were found in FFM (-0.9±2.3 %, -5.4 to 3.1 %), LST (-0.9±2.4 %, -5.8 to 3.2 %), arms LST (-1.7±4.4 %, -9.9 to 4.2 %), TBW (-0.6±3.7 %, -9.2 to 5.9 %), ECW (-0.8±4.8 %, -15.8 to 5.9 %), ICW (-0.4±5.4 %, -10.9 to 8.6 %), energy intake (-6.2±27.9 %, -54.1 to 54.9 %), and FMS (0.7±7.5 %, -16.3 to 18.6 %). From all the above variations in body composition variables, changes in FMS were only significantly related with changes in ICW ($r=0.559$, $p=0.003$) but not with changes in TBW ($r=0.338$, $p=0.091$); the significant association of ICW and FMS alterations remained after controlling for weight and arms LST changes ($r=0.558$, $p=0.005$) which means that those athletes that lost water from the intracellular compartment were those that reduced forearm maximal strength, even after adjusting for the potential effect of variations in weight and arms LST observed before a competition. CONCLUSION: These findings highlight the need of assessing and tracking total-body water, specifically the intracellular water compartment, in elite Judo athletes to avoid reductions in grip strength when a target body weight is desired before a competition.

ANALYSIS OF TYPOLOGICAL STRUCTURES OF SITUATIONAL EFFICIENCY IN JUDO FOR FEMALE JUNIOR COMPETITORS

KAJMOVIC, H., RAĐO, I., KAPO, S.

FACULTY OF SPORT AND PHYSICAL EDUCATION, UNIVERSITY OF SARAJEVO

Introduction: Efficient action of judo for female juniors comperitors, cannot be described as uncontrolled or unorganised, in the same manner as it is not possible that at a certain moment all these typological indicators are maximised at the same time (Kajmović at al., 2007). This research is intended to establish typological situational judo structures for female competitors, is focused on achievement of scientific fact which will have permanent character and which will be used in future as a solid ground for resolution of particularly applicative task in judo. Therefore, the problem and the subject of this work is clearly articulated, and is related to establishment of rules existing at the latent level of situational action in judo, for female competitors. Innovative technique in this work defines as entities the fights and not individual fighters, simply since in this way one can gain more detailed information on existing rules as well as interactions.

Methods: For the purpose of this work the sample used was 126 junior female competitors from 38 European countries, in all weight categories, coming up to 179 fights between female competitors at European championship U-20 for juniors held in Sarajevo, 2003. Each competitor was described with 133 parameters out of which, after the elimination of such variables with exclusively zero values, there were 74 left. Initial results were carefully recorded through watching of VHS tapes, what made the situational aspect of the research really credible.

Results: The data processing was performed in such a way which allowed production of useful information at all levels of analyses multivariant complex models, in which a special place belongs to relation model of action. Results of this research give us the right to see the situational efficiency of judo female competitors comprises one latent dimension, which is separate in: a) tactical action b) global and strategic action, and c) action focused on technical segment.

Discussion: Understanding is seen in the possibility of recognition of isolated latent action mechanisms in situational aspect. Through this the research involves interpretability and repetitiveness, as well as the possibility to compare the results with other patterns and populations. This situational model is composed out of individual building elements representing the wish to win, the knowledge of conditions of realisation of activity and accumulation of efficient actions. A special segment to this theoretical model is added by the fact that the judo fighter has to have a precisely combined match which will give as a result a maximisation of each individual structural element.

EVALUATION OF THE RAPIDITY REACTION IN KARATE

DISTASO, M., CECCACCI, A., GASPERINI, D., GIANGRANDE, M., VILLANI, R.

UNIVERSITY INSTITUTE OF CASSINO - MOTOR SCIENCES FACULTY

Introduction: The aim of the research is to evaluate the rapidity of reaction and action in karate techniques. We compared the speed of the techniques of the athletes of kata and kumite categories to confirm that the athletes who practise kumite are really more reactive than the others, as. We started the experimentation of the SOR test (reaction speed) which survey the actual rapidity of reaction in response to visual stimulus.

Methods: To perform the SOR test we used an ergotest which records the inputs coming from a photocell and a luminous starter, which allows to determine the reaction time for each technique. A piezoelectric footboard was placed nearby a punching bag to check the total time of the action, allowing to stop the chronometer of the ergotest when the athlete finishes his execution.

The experimentation was conducted over a group of 20 male athletes who practice karate (age:18/30; height:170/192; weight: 60/94; degree: brown/black), divided into 2 similar groups: 10 katà and 10 kumitè competitors. We examined 4 techniques: 2 attack techniques with hands, kizami tsuki and gyaku tsuki (leading punch and reverse punch) and 2 attack techniques with foots, kizami mawashi geri and

mawashi geri (front roundhouse kick and round kick). The objectivity was guaranteed by an accurate standardization of the protocol. The whole series of tests was repeated after two days to carry out the reliability study. It was also made a cross-comparison between the results of the group of the athletes performing kumitè and the group of athletes performing katà, in order to study the validity of the test and to check the ability to distinguish the athletes performing different disciplines. The reliability of such difference was studied through Anova Methods: Results: The reliability study (test-retest correlation) pointed out r values included between 0,80 and 0,91 ($p<0.01$) for both the groups and the 4 techniques analyzed. In the cross-comparison the group performing kumitè resulted significantly more rapid in responding to stimuli than the group performing katà, with high percentage differences (kizami tsuki = 31%, $p<0,0001$; gyaku tsuki = 32%, $p<0,0001$; kizami mawashi geri = 25%, $p<0,01$; mawashi geri = 27%, $p<0,01$). On the contrary, there wasn't a significant difference between the 2 groups in the overall time of execution of the techniques, with percentages varying from 3 to 7%.

Conclusions

The results of the experimentation allow us to state that karate's athletes performing kumitè speciality have a rapidity of reaction superior than those performing katà. Probably this is due to the fact that in katà responding rapidly to external stimuli is not so important as execution rapidity, as happens in almost every technical and combinatorial sport.

HEART RATE VARIABILITY AT REST AND DURING EXERCISE OF CHEN-STYLE TAIJI QUAN PRACTITIONERS

VARGA-PINTER, B., PETREKANITS, M., PAVLIK, G.

SEMMELWEIS UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPO

Taiji Quan (TJ), as a moderate physical activity, has an influence on resting heart rate (HR) (Lan et al. 2004), however, few articles deal with heart rate variability (HRV) (Vaananen et al. 2002).

Aim: Our aim was to measure HRV of advanced Chen-style (the root of all TJ styles) TJ practitioners at rest and follow their HR changes during a training session.

Subjects and Methods: Measurements were made in 10 males of the advanced group (age 34±5.2 yrs, years of practicing TJ 6.6±3.4 yrs, training time 11.2±5.5 hrs/wk). Resting HRV was measured before practice with a POLAR Vantage NV watch and belt and during the session they wore a Team POLAR belt. One training session includes a 30-min warm-up -10 min stretching, 15 min practice of kicks and punches and 5 min acupoints' stimulation – a 26-min 83-step form and finally a 34-min of push hands. Evaluation of results occurred with POLAR Precision Performance 2.0 and SW.

Results: At rest HR was found on the average 73±14.5 bpm. Index stda and stdb (standard deviation of instantaneous and long-term R-R interval variability) was 79.9 ms and 32.6 ms, only one person had low indices (12.7 ms and 2.6 ms). pNN50 (percentage of difference between adjacent R-R intervals that are >50 ms) values' distributed from 0% to 37%, avg:10.6%. Distribution among very low (VLF), low (LF) and high frequency (HF) power was 35.4%-45%-19.6%, respectively. Three practitioners had very high (over 1000%) LF/HF ratio. From the level of HR in warm-up part one (88±7.1 bpm), kicks and punches increased the HR to 124±17 bpm. During 83-step form the HR was 118±10.3 bpm, and during push hands it was 116±8.2 bpm.

Discussion: Based on HRV, subjects arrived to the class in a good average cardiac state. The first part of warm-up raised their HR to the level of 53-57% of their maximal HR reserve, the second part took the biggest load on individuals (until 61-71%), during the form everyone's HR decreased to 59-68% and curiously, though the 83-step form is a slow-form of Chen-style, in the fighting part practitioners' HR was significantly lower ($p<0,05$) than at the end of the form.

Conclusion: Though Chen-style TJ is an inner-style kung-fu, an advanced Chen-style TJ training differs from other TJ classes we can read about; it rather resembles to an outer-style kung-fu class. On the other hand, we are sure about that practicing the form alone, Chen-style TJ has the same effects as other authors has mentioned about other styles.

DOKUZ EYLUL UNIVERSITY, İZMIR

Introduction: Purpose of this study is to investigate the effects of upper extremity plyometrics on throwing velocity and isokinetic muscle strength of shoulder rotators in female team handball players.

Methods: Sixteen subjects were volunteered to participate to this study. The subjects were randomized into plyometric exercises group (PG) (n=8) and daily training control group (CG) (n=8). Plyometric group (PG) performed plyometric exercises in addition to their daily training while control group (CG) just executed their daily training. Throwing velocities were tested in two types of throws which were standing throwing velocity (STV) and 3-step throwing velocity (3STV). Shoulder internal (IR) and external rotation (ER) peak torque were examined in 90, 300 ˚/s velocities before and after six weeks plyometric training period.

Results: Throwing velocities significantly increased in both PG and CG (P<0,05). Peak torque of IR (300 ˚/s) in dominant arm and peak torque of ER (90 ˚/s) in non-dominant arm were significantly increased in PG (P<0,05). Also, peak torque of IR and ER (300 ˚/s) in dominant arm and peak torque of IR (300 ˚/s) in non-dominant arm were significantly increased in CG (P<0,05). But when both groups compared there were no significantly difference neither throwing velocities nor peak torques. There was a significant positive correlation between STV and peak torques of IR (90, 300 ˚/s) (r=0,56 P=0,01, and r=0,52 P=0,01 respectively). There was a significant correlation between peak torque of ER (90 ˚/s) and 3STV (r=0,49 P=0,02).

Discussion: Upper extremity pylometrics are used commonly in handball training (Kvorning T., 2006) but there is no avialable study in the literature. Some findings of throwing velocities after plyometric exercises conflict with a research in baseball which is similar with overarm throwing (Carter et al., 2007). It seems to six weeks plyometric exercises have no additional improvements on throwing velocities and isokinetic muscle strength of shoulder rotators in female handball players in our study. Altough we could not show any additional effect of plyometrics, we think that it could integrated into the handball training as a sport specific exercise.

JUMP CAPACITY AND THE ACL INJURY IN FEMALE HANDBALL PLAYERS

ESTRIGA, L., CARVALHO, J., BERNARDES, J., MASSADA, L.

UNIVERSITY OF PORTO

The risk of ACL injuries seems to be higher in adolescents and young female athletes in comparison to male athletes of the same age. In handball, the lower limb muscle strength is essential to perform faking movements, changes in direction, accelerations and jumps. These actions are also the most frequently implicated in the ACL injuries mechanism.

Purposes: to examine the influence of maturation, oral contraceptive status, previous knee injuries and handball exposure in jump performance.

Sample: 496 Portuguese female handball players, 16±4 years old, practicing handball for 6±5 years. A cross-sectional experimental design was employed in the 2006-07 season. The testing sessions included initial anthropometric measurements, including standing body height, body mass and percentage of fat mass (by bioelectrical impedance). A screening questionnaire was used to assess some vital data, previous knee injuries and sports related information. Vertical jump tests were used to assess lower limb muscle strength: the squat jump (SJ) and counter-movement jump (CMJ). A contact platform was used to assess the height jumped. The m-eccentric utilization ratio (mEUR) was defined as CMJ/SJ-1.

Results: A stepwise regression on the jump performance revealed that there is a significant dependence only on age, BMI and field position (p<3%).

The dependence on age is well described by 3rd degree polynomials (r2>79%) with a minimum at the start of the series (10 years) and a maximum at about 28 years. However, the CMJ and SJ evolve similarly (r2=0.75), what means that the elastic energy utilization, a frequent indicator of jump competence, has no significant trend during the players careers (r2=0.03). This is unexpected and in contrast with published data.

We have found a small increase in jump performance around the menarche age, not different from other improvements during other phases of the players' careers (average of 5cm in 4 years).

On BMI, the jump performance dependence is less clear. Both CMJ and SJ are best described by parabolas with peaks at around 22.6kg/m2 but the fits have low adherence (r2>40%). They are also almost parallel along all range.

There is a statistical relation between field position and jump capacity. While left and right back players, as well as left-wingers, tend to have the higher jump capacities, pivots and right-wingers tend to be on the opposite extreme.

Finally, we have observed that players without previous knee injuries have a lower SJ capacity than players with previous knee injuries (p<4%).

Conclusions:Maturation per se is not has decisive on jumping performance as training.

The absolute jumping capacity, the mEUR values and it's evolution along ages may all be interpreted as a sign of a conditionally under trained population, possible at higher risk of ACL injury due to low dynamic knee stabilization capabilities.

Hormonal therapy does not have a significant effect on jumping performance.

STRENGHT AND ENDURANCE PERFORMANCE IN TRADITIONAL ROWING

SAEZ-SAEZ DE VILLARREAL, E., IZQUIERDO-GABARREN, M., RAFAEL GONZÁLEZ DE TXABARRI, R., IZQUIERDO, M.

UNIVERSITY PABLO DE OLAVIDE (SEVILLA)

The purpose of this study was to examine the performance factors between elite (ER) and amateurs (AR) traditional rowers and the relations between the measured variables to determine the best predictors of traditional rowing performance. Average power during the 20 minutes´ all-out test (W20min), average power output which elicited a blood lactate concentration of 4mmol•l-1(W4mmol•l-1), power output in 10 maximal strokes (W10strokes), maximal strength and muscle power output during a bench pull (BP) and anthropometric values were measured in 46 trained male rowers aged 21 to 30 with 8-15 years of rowing training experience. ER group showed higher body mass (5%, p <0.05), free fatty mass (5%, p <0.05), age (21%, p<0.001), training experience (43%, p<0.001), and lower time in 2000m test (4%, p <0.05) than AR group. Average power output and power output index were higher in ER group (from 6% to 13%; p<0.05-0.01) than in AR. ER group exhibited higher power output values in W10strokes (9%, p<0.01), and in average power during W20min (15.4%, p<0.01) compared with AR group. During W4mmol•l-1 the mean stroke power output was 17.8% higher (p<0.01) in the ER than in the AR group. Significant relationships were observed between W4mmol•l-1 and W20min (r = 0.65 and 0.80; p<0.01 in ER and AR, respectively). ER groups was characterized by having higher body mass, having a greater percentage of free fatty mass and obtain significantly better results in the rowing performance test than AR. The indices of rowing performance suggested that W20min, W4mmol•l-1, W10 stokes and 1RMBP were the most important predictors of traditional rowing performance in elite and amateur rowers.

STRESS AND RECOVERY OF NEW ZEALAND JUNIOR ROWERS PREPARING FOR THE 2008 WORLD CHAMPIONSHIPS: COMPARISON TO THE 1998 GERMAN NATIONAL ROWING TEAM

NOTTLE, C., VAN WARMERDAM, M.

WAIKATO INSTITUTE OF TECHNOLOGY

Introduction: Manipulation of training load is a key stimulus for improved performance, however overtraining can result in performance declines and burnout. Previously Kellmann et al [1] examined the stress, recovery and training duration of the German (GER) Junior Rowing Team preparing for the 1998 World Championships. The aim of the current investigation was to compare these results with the stress, recovery and training duration of the New Zealand (NZL) Junior Rowing Team preparing for the 2008 World Championships.

Methods: Athletes from the New Zealand Junior National Rowing Team volunteer for the study (N=24, mean±SD age: 17.4±0.5 years, height: 181.3±9.5 cm, weight: 81.3±10.1 kg, ∑8 skinfolds: 73.1±20.9). Athletes were monitored for 5 weeks of a training camp held immediately prior to the 2008 World Junior Championships. Athletes completed five Recovery-Stress Questionnaires for Athletes (RESTQ-Sport) and a daily training diary outlining mode, duration and intensity of training. Descriptive data (mean±SD) for each scale of the RESTQ-Sport and training duration was determined for each week. These data were compared with data presented for the German athletes via determination of z- or t-scores.

Results: No differences in training duration between the two groups was recorded (t=0.5) with average weekly durations of 1090 and 1109 hours reported for the NZL and GER athletes respectively. For the stress scales: NZL athletes reported significantly higher scores for emotional stress (z=5.6), social stress (z=3.16), conflicts/pressure (z=3.9), fatigue (z=4.9), lack of energy (z=12.5) and physical complaints (z=7.8). For the recovery scales: NZL athletes reported significantly lower social recovery (z=-11.6), physical recovery (z=-4.6), general well being (z=-4.8) and sleep quality (z=-10.0). For the sport specific scales: NZL athletes reported significantly higher scores for disturbed breaks (z=8.6), emotional exhaustion (z=12.0), and injury (z=10.1) and significantly lower scores for being in shape (z=-3.6) and self efficacy (z=-2.6). At their respective events the GER athletes placed in 14/14 A finals (14 crews), with the NZL athletes placing in 3/3 A finals (5 crews).

Conclusions: While comparisons indicated no differences in training duration, the NZL athletes demonstrated higher stress and less recovery compared to the GER athletes. It is possible this is the result of differences in training intensity not duration, which is demonstrated to be related to overtraining (Halson et al. [2]). Although it is difficult to compare the performance outcomes of the teams, the long term consequences of high stress: low recovery for the NZL athletes may be a concern with regards to athlete development, and progression to seniors, due to the relationship between stress- recovery and burnout.

HEART RATE VARIABILITY AND VO2 MAX, DURING A ROWING TRAINING SEASON: IMPLICATIONS FOR MONITORING TRAINING ADAPTATION.

RAMA, L., TEIXEIRA, A., SANTOS, A., GOMES, B., MASSARD, A., ROSADO, F., ALVES, F.

FACULTY OF SPORT SCIENCES AND PHYSICAL EDUCATION OF COIMBRA

Objectives

In Sport Science it is generally accepted that aerobic training promotes higher Heart Rate Variability (HRV) and that intense training leads to lower HRV. The aim of this study was to analyze the utility of heart rate variability as a marker of training adaptation during a rowing training season and it's sensibility to training load variation.

Methods: 9 males of the national rowing team (22,2 ±2,0 years, 181,2±7,2cm height, 77,9±8,1Kg mass) were selected for this study. HRV time domain (SDRR) and frequency domain (LF, HF absolute, relative and normalized units as was the LF/HF) were measured at rest before a graded test conducted on a Concept II rower ergometer. VO2max, was evaluated and 4 time points controlled according to a year training plan. The first evaluation (t1) took place in the begging of the training season after a transitory period during which the athletes had been released for 5/6 weeks from their normal training. This allowed us to find out the basal values at the beginning of preparation for the sport season. The second evaluation (t2) was done after the first 14 weeks of training with great aerobic predominance and a gradual increment of training volume. The third evaluation (t3) took place at the 28th week, after a phase of intensity increment and a small decrease on training volume. The final evaluation (t4) coincided with a training phase with the highest mean weekly volume and intensity during the season and before a taper period. In this study we adopted a single group repeated measures design in which athletes served as their own control subjects. All ethical presuppositions that a study of this scope compels have been verified.

Results: During the season, VO2max values were: t1=61,49 ± 6,21 ml.kg.min-1; t2=65,37 7,9621 ml.kg.min-1; t3=66,72 6,8021 ml.kg.min-1 and t4 =64,82 8,3021 ml.kg.min-1.

The VO2 at t3 was significantly higher (p<0,05) than that observed at t1 and t4. Nevertheless the power at VO2max was from t1 to t4 respectively 334 34, 378 40, 377 52 and 387 45 Watts, higher at all moments when compared to t1 (p<0,05). Concerning HRV, we found SDRR higher at t3 (p<0,05) and lower at t4, and lower absolute HF(nu) and higher LF (nu) at t3 when compared to the initial values at t1. In summary, during the season at t3, when metabolic values of VO2max were higher, we also found the highest SDRR as marker of global variability, and the lowest LF and highest HF, which indicates a parasympathetic drive on autonomic control of the heart. Also the LF/HF shows a progressive increase during the season, although never attaining a significant variation.

Conclusions

Our results agree with those (1) who found a relationship between aerobic capacity development and the predominance of the parasympathetic on the sympatho-vagal balance, and confirmed the utility of at rest HRV control in monitor training adaptation on rowers during a training season.

DOES ELECTRICAL STIMULATION OF KNEE EXTENSOR AND FLEXOR MUSCLES INDUCE DOMS?

VANDERTHOMMEN, M., TRIFFAUX, M., DEMOULIN, C., CRIELAARD, J.M., CROISIER, J.L.

UNIVERSITY OF LIEGE

Introduction: Neuromuscular electrical stimulations (NMES) are frequently used to improve muscle performance. It has been shown that the gains observed at the end of a NMES program depend on the intensity of the contractions that are electrically evoked during the training sessions. Therefore, it is suggested to prompt subjects to tolerate the highest current intensity as possible. The present work aimed to study the effect of an intense NMES session on muscle soreness and tightness.

Methods

Ten physically active men (24 ± 3 years, 181 ± 4 cm, 74 ± 11 Kg) underwent unilaterally, isometrically and consecutively 20 min of quadriceps (Q) and 20 min of hamstrings (H) NMES. The stimulator provided biphasic rectangular pulses (80 Hz, duration 0.35 ms, on-off ratio 6-6 s) and the current intensity was continually increased throughout the session at maximal tolerable level (~ 75 mA at the end of both bouts). Torque measurements were performed using an isokinetic dynamometer (Biodex3). Subjective perception of muscle soreness was evaluated by the Visual Analogue Scale (0-10 a.u.). Flexibility of the Q was tested with the prone quadriceps flexibility test (distance between heel and buttock with the knee maximally flexed) and the H flexibility was tested with the straight leg raising test (hip angle). Creatine kinase (CK) activity was measured from blood sampling. All parameters were evaluated before as well as 24 h (d1) and 48 h (d2) after the NMES provocation bout.

Results: During the NMES bout, the stimulated contractions reached, in mean, 31% and 19% of maximal voluntary torque (MVT) for the Q and the H, respectively. All measured variables were significantly modified after the electrostimulated exercise. The highest variations occurred at d2 (mean VAS scores = 3.15 ± 1.83 a.u.; mean reductions in Q flexibility = +3.2 cm; mean reductions in H flexibility = –13°; mean CK activity = 3021 ± 2693 IU/l).

Discussion: Generally, DOMS occur in skeletal muscle after strenuous exercise, especially when high peak forces are involved during eccentric contractions (Croisier et al., 2003). In the present study, we showed that one session including NMES of quadriceps and hamstrings muscles, realized isometrically and inducing sub-maximal contractions (~ 20-30% MVT), provokes muscle soreness and stiffness and increased CK activities suggesting the occurrence of DOMS. Those DOMS could be induced by the specificities of NMES i.e. temporal and spatial recruitment (Vanderthommen and Duchateau, 2007). The fact that a NMES session, realized in conditions close to the field conditions of training or rehabilitation in terms of stimulation parameters, electrodes positioning and intensity adjustment, can induce an alteration in muscle function constitutes a relevant information.

PROFILING ANTHROPOMETRIC AND ISOKINETIC STRENGTH CHARACTERISTICS IN 14-15 YEARS OLD BASKETBALL PLAYERS.

CARVALHO, H.M., MACHADO RODRIGUES, A., FIGUEIREDO, A.F., GONÇALVES, C.E., GONÇALVES, R.S., PHILIPPAERTS, R., COELHO E SILVA, M.J.

UNIVERSITY OF COIMBRA

Explosive muscle strength and muscular balance of the knee joint are important parameters to succeed in basketball. Isokinetic testing has been consistently used for assessment of concentric and eccentric strength of the knee joint musculature. The literature is more abundant for soccer players (Sangnier & Tourny-Chollet, J Strength Cond Res, 22: 2008) than for other team sports, in general, and basketball, in particular. In addition, isokinetic assessment has not been systematically considered in adolescent basketball players taking into account growth characteristics. The present study examines the isokinetic parameters of the knee joint musculature in 14-to 15-year-old basketball players by playing position.

A total of 51 basketball players (14.0-15.9 yrs; 2-11 years of training) were categorized as guards (n=16), forwards (n=21), and centers (n=14). Anthropometry included those measurements needed for estimation of leg volumes (Jones & Pearson, J Physiol, 204: 1969), plus stature and body mass. After a 5-min warm-up at 60 rpm in a cycle-ergometer (Monark) and stretching, subjects performed five maximum knee extensions (KE) and flexions (KF) in the isokinetic dynamometer (Biodex system 3, Biodex Corporation, Shirley NY, USA) programmed at 60 degrees/s (modes CON and ECC in both legs. Moments were corrected for the effect of gravity and the highest moment from the five trials for each contraction mode was retained for analysis. Parameters for analysis were absolute peak torque (PT), relative peak torque (PT per kg of body mass), 'functional' and 'conventional' hamstrings to quadriceps (H/Q) ratios and bilateral differences (Aagaard et al, Am J Sports Med, 26: 1998). Analysis of variance (ANOVA) was used to test position-related variation in body size and strength parameters. Significance level was set at p≤0.05.

As expected, centers were taller ($F=12.251$; $p < 0.01$) and heavier ($F=11.021$; $p < 0.01$) than guards and forwards, whereas forwards had similar stature and body mass as guards in this age group. Results in PT showed differences, from centers to both forwards and guards, in mean ECCKF in the dominant leg ($F=3.979$; $p<0.05$). Also in the non-dominant leg differences revealed in mean ECCKF ($F=4.203$; $p<0.05$) and ECCKE ($F=4.392$; $p<0.05$). No differences were found in mean CON PT, as well as H/Q ratios and bilateral differences.

The present studies showed a significant position-related variation of body size and absolute peak torque. When expressing isokinetic strength per unit of body mass the effect of playing position was not anymore significant. Future research including maturational assessments is needed during pubertal years. It would also be of interest to investigate the effect of playing position in players accumulating more years of basketball practice. The current ongoing project will report the relationship between isokinetic outputs and concurrent anaerobic tests.

DIFFERENCES IN PROPRIOCEPTIVE QUALITIES OF THE FOOTBALL PLAYERS AT DIFFERENT LEVELS OF COMPETITION IN BOSNIA AND HERZEGOVINA

HARIS, A., RAĐO, I.

FACULTY OF SPORT AND PHYSICAL EDUCATION, UNIVERSITY OF SARAJEVO

Introduction: Football game comprise all forms of natural movements as running, stopping, turning, jumping, falling, throwing, pushing, and occur with different intensity, tempo and duration, with purpose of defending and attacking actions (Rađo et al., 2002). Balance abilities of players are very important for the function of maintaining adequate body posture while shooting, pushing, and landing, and especially for injure preventing. Purpose of the research was to find differences in balance ability, propriocetive qualities of players at different levels of competition in Bosnia and Herzegovina.

Methods: Study from the season 2007/2008, involved 129 players, seniors, from different level of competition (five levels): level-I (National team), level-II (Premier League), level-III (First League), level-IV (Second League) and level-V (Cantonal League). Biodex Stability System was used to test balance ability of players, stability level 4, duration of 20sec, stability index was recorded. T-test for independent samples was used for difference determination between levels.

Results: Results of the study has shown statistically significant differences between third (First League) and fourth (Second League) levels. $p<.05$, in favor of the level four, while between other levels there was no statistically significant differences recorded. Average value of the stability index were as follows: level-I (National Team) 6.1, level-II (Premier League) 6.8, level-III (First League) 7.3, level-IV (Second League) 5.4, level-V (Cantonal League) 6.7.

Discussion: Results of the study didn't show expected differences between levels of competition. Differences in balance ability were notable only between levels three and four. Differences between levels were expected to be in favor of quality of the competition, but that was not the case (Alic, 2008). We assume that proprioceptive training was disregarded at the all tested levels of competition and that is the reason why there were no differences between levels.

CHANGES IN VERTICAL GROUND REACTION FORCES WITH FATIGUE DURING THE SERVE IN TENNIS

GIRARD, O., MILLET, G.P., MICALLEF, J.P.

ASPETAR - QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL

Introduction: Recent biomechanical analyses of the tennis serve have focused on lower extremity kinematics, ground reaction forces (GRF) or EMG activity of selected leg muscles, underlying the importance of a forceful lower limb drive to produce efficient strokes. A decrease in isometric maximal voluntary strength capacity of both knee extensors and plantar flexors has been reported after prolonged tennis playing. However, strength losses with fatigue - as measured previously from isolated leg muscle contractions - do not necessarily reflect changes in lower limb involvement during dynamic/functional movements such as tennis strokes. Therefore, it is still unknown if fatigue alters the lower limb drive during the serve.

The purpose of this study was to examine the impact of prolonged tennis playing on vertical GRF during the serve.

Methods: Nine competitive tennis players randomly executed 10 flat (first, FS), 5 slice (first, SS) and 5 twist (second, TS) serves before and after a 2 h 30 min tennis match. All serve trials were completed from the deuce service court at match pace. Vertical maximal GRF (Fzmax) and post-impact ball velocity were determined for each trial by means of force platform (Captels, France) and radar (Stalker, USA), respectively.

Results/Discussion: Ball velocity did not change from pre- to post-exercise (FS: 158.7±11.5 vs. 154.7±11.5 km.h-1, -2.5%, P=0.099; SS: 138.2±21.6 vs. 136.5±20.8 km.h-1, -1.1%, P>0.05; TS: 126.3±20.2 vs. 124.9±15.3 km.h-1, -0.4%, P>0.05). In the literature, contrasting effects of fatigue on tennis serve efficiency have been reported depending on service type, nature of fatiguing protocol or subjects' characteristics. In the fatigued state, Fzmax was unchanged (P>0.05) in FS and SS (1.78±0.30 vs. 1.72±0.29 and 1.60±0.22 vs. 1.65±0.22 BW; -2.9 and +3.8%; before and after the tennis match, respectively). In line with these findings, no significant changes in explosive strength - as measured from squat and countermovement jumps - were observed after a tennis match protocol of the same duration. Unexpectedly, our results also displayed an increased Fzmax (1.62±0.25 vs. 1.75±0.23 BW; +8.2%; P<0.001; before and after the tennis match, respectively) in TS under fatigue. Since the ball velocity was unchanged, this stronger lower limb involvement during TS under fatigue might indicate that the contribution of other body segments participating to the kinetic chain (trunk, upper limbs) is modified. This is further supported by the absence of significant correlation between changes in Fzmax and ball velocity ($0.03 < r < 0.62$; P>0.05) from pre- to post-exercise.

Conclusion

After a prolonged tennis match, ball velocity remains unchanged while the effects of fatigue on the lower limb drive are different according to the service type. This indicates a modification in inter-segments coordination that requires further kinematic and kinetic analyses coupling.

PP-TT05 Training and Testing 5

APPLICABILITY OF THE YOYO INTERMITTENT RECOVERY TEST LEVEL 2 FOR THE ASSESSMENT OF REPEATED HIGH-INTENSITY RUNNING CAPABILITY IN YOUTH PROFESSIONAL SOCCER PLAYERS

MUKHERJEE, S., CHIA, Y.H.M.

NATIONAL INSTITUTE OF EDUCATION, NANYANG TECHNOLOGICAL UNIVERSITY

Introduction: In soccer, the higher the level of performance, the greater is the amount of high-intensity running performed by the players. The YoYo Intermittent Recovery Test (YoYo IRT L2) is a reliable and valid measure for assessing repeated high-intensity running capability in elite adult soccer players. However, the applicability of this test in youth professional soccer players is apparently not yet evaluated. The aim of the study was to evaluate the applicability of the YoYo IRT L2 for the assessment of repeated high-intensity running in youth professional soccer players during different phases of a complete soccer season.

Methods

Twenty youth professional soccer players (mean ± SD: age, 17.5 ± 0.3 years; stature, 1.73 ± 0.04 m; body mass, 67.2 ± 7.5 kg) participated in the study. The participants completed a laboratory-based test of intermittent high-intensity on a motorized treadmill, the YoYo IRT L2 as a field-based test of intermittent high-intensity running, a repeated sprint ability (RSA) test on a non-motorised treadmill (6 × 6 s with 24 s recovery) and a field-based RSA test (8 × 20 m with 15 s active recovery) on three occasions (pre-season, early in-season and end mid-season) during the soccer season. The study also determined the work intensity during match play using heart rate (HR) monitoring for two matches during each phase of the competition season.

Results: Significant correlations ($p<0.05$) were observed between the laboratory test of intermittent high-intensity running (Range; $r = 0.53$-0.85) and performance in the YoYo IRT L2 (Range; $r = 0.55$- 0.81) with the amount of high-intensity work performed during match play (HR > 90% of HRmax for % of total playing time). Non-significant correlations were found between the tests of RSA and match play work intensity. Results also showed that the performance in the YoYoIRT L2 (distance covered, mean; 818, 950*, 1032 m; * significant change from the previous phase) and the amount of high-intensity work performed during match play (57.5, 69.5*, 58* %) changed through the soccer season

Discussion: The development and assessment of repeated high-intensity running capability should be of important concern for soccer scientists and coaches. The results strongly supported the validity of intermittent high-intensity running tests for the evaluation of match performance in youth professional soccer players in terms of high-intensity work performed during matches. However, the YoYo IRT L2 being field-based, simple to conduct, with the option of simultaneous multiple player testing and therefore is time economical. The YoYo IRT L2 has an advantage over the laboratory-based test that requires specialized facilities and manpower. Furthermore, the results showed that the YoYo IRT L2 was sensitive to the changes in the repeated high-intensity running capability through the playing season in youth professional soccer players.

COMPARISON OF ANTHROPOMETRIC, BODY COMPOSITION, AND PHYSIOLOGICAL CHARACTERISTICS OF IRANIAN NATIONAL TEAM AND PREMIER-LEAGUE FUTSAL PLAYERS

GHARAKHANLOU, R., ESLAMI, R., PARNOW, A.H.

UNIVERSITY

The purpose of this study was Comparison of Anthropometric, Body Composition, and Physiological Characteristics of Iranian National Team and Premier-League Futsal Players. A number of 16 Futsal players of Iran National Team (INT) (25.93± 3.88 age) and a number of 16 players present in Iranian premier-league (IPL) (26.12 ± 4.01 age) of Futsal were tested. As anthropometric characteristics, thigh circumference and length, calf circumference and length, and sitting height and as body composition characteristics, height, weight, body fat percentage, lean body mass, and BMI were measured. Physiological profiles were composed of aerobic and anaerobic power, speed (10 & 20m run), agility, and flexibility. For lean body mass, BMI, agility, and 10m speed, there is significant difference between INT and IPL groups (respectively, $p= 0.031$, $p= 0.017$, $p= 0.009$, $p= 0.005$). In summary, these results showed that some of body composition and physiological characteristics were higher in INT players than ILP players. These results can help coaches in players choosing.

TECHNICAL ABILITIES IN FEMALE FUTSAL

BENVENUTI, C.

UNIVERSITY OF ROME FORO ITALICO

Cinzia Benvenuti, Antonio Tessitore, Corrado Lupo, and Laura Capranica

Department of Human Movement and Sport Science, IUSM, Rome, Italy

Introduction: Despite the growing worldwide popularity of Futsal, few studies provided information on motion analysis (Barbero et al. 2008; Castagna et al., 2008) and tactical aspects (Amaral and Garganta, 2005), of men's players, while only one study reported the tactical situations relevant to score a goals in women's matches (Benvenuti et al., 2008). Since no data are available on technical abilities of female players, this study aimed to analyze the occurrence of individual's technical aspects in relation to the different zones of the pitch (i.e., zone 1-2, and zone 3-4 respectively for defensive and offensive mild field).

Methods: The performance of eight female players were analyzed during the Italian Futsal Cup 2008 Final Eight. When the team had the possession of the ball (PB), the following indicators were selected: Dribbling (D), Passing (P), Receiving (R), Shooting (S), and Free from marking (F). The indicators during phases of non possession of the ball (NB) were: Covering (C); Intercepting (I), and Anticipation (A). An ANOVA was applied to verify differences ($p<0.05$) between the following roles: central defenders (CD), defender wings (DW), offensive wings (OW), and pivot (PV).

Results: In relation to the field-zones, PB showed the highest occurrence of D, P, R, and F in zone 3 (45%, 40%, 41% and 52%, respectively), while S occurred most frequently in zone 4 (55%). During NB, C, I, and A occurred most frequently in zone 2 (43%, 40%, and 37%, respectively). Although no difference emerged between roles in the amount of technical actions, different specific characteristics emerged, with CD showing highest values of D (49%) and A (37%), P the highest values of A (50%) and F (47%), DW and OW the highest frequency of occurrence of P (30%) and R (DW:33%; OW: 29%). Furthermore, DW shooted most frequently (40%).

Conclusions: Although teams defend from zone 2, most of the technical aspects of the attacking teams occur in zone 3 and players tend to shoot from a reduced distance from the goal (i.e., zone 4), probably due to a limited strength in their lower limbs. The individual's indicators highlighted that CD needs more dribbling and anticipation capabilities to structure the offensive action. On the other hand, the players mainly involved in the tactical rotation (i.e., WD and WO) need more passing and receiving capabilities, while the PV places more efforts to get free form marking during attacking actions and to anticipate while defending.

THE EVALUATION OF PHYSICAL AND TECHNICAL CHRACTERISTICS OF AMATEUR SOCCER PLAYERS

POLAT, C., CERRAH, A.O., ERTAN, H.

ANADOLU UNIVERSITY

Introduction: The purpose of the current study is to evaluate the physical and technical characteristics of soccer players playing in regional amateur league.

Methods: 89 amateur soccer players has volunteered to the study from different positions (goal keeper (n=9), defense (n=25), midfielder (n=41) and striker (n=14). Subjects were familiarized with the testing protocol via two sub-maximal practice attempts (Jeremy et. all., 2007). 10, 20 and 30 m sprint scores have been measured. HUFA, which supplies information on both technical index and technical score, is a measurement station developed by Ozkara et.all. (2002). Measurement station is totally 30m including slaloms. The subjects performed two jumping protocols [(1) squat jump (SJ) and (2) countermovement jump (CMJ)] on BOSCO jumping mat. Each player performed 2 SJs and CMJs. The best jump of each jumping protocol was selected for analysis (Chamari, et all., 2004). Strength was determined isometrically for back pull-leg lift. The higher trial of two was used for analysis. Maximum voluntary back/leg strength was measured using a digital back/leg dynamometer (BCS-400, range: 0–500 kg, graduation: 1 kg). Flexibility test include sit and reach tests. The main function of sit and reach tests are to determine the hamstring and trunk flexibility. Body weight and height have been measured. Holtain calipers have been used to measure the skin thickness on four sites of the body. Body-density values was calculated from the by use of the Siri equation (1956).

Results: Sprint values consisting 10m, 20m and 30m has shown no statistical difference in terms of players' positions ($p>0.05$). Besides, there was no significant difference among the players' position from technical index aspect. However, a significant difference has been calculated ($p<0.01$) in between goalkeepers and defense players in terms of technical scores. The defense players have covered the distance in a shorter duration than goal keepers with ball. The same difference has been observed between goalkeepers and midfielders. No significant difference has been observed among amateur players in terms of the percentages of body fat values and body mass indexes (BMI), flexibility, SJ and CMJ and back-leg strength values ($p>0.05$).

Discussion: The amateur players didn't show the characteristics of their playing positions when compared with the literature. It can be concluded from the current results that the training program they have does not include the principle of training specificity.

OSCILLATIONS IN SMALL-SIDED SOCCER GAMES

FRENCKEN, W., VISSCHER, C., LEMMINK, K.

UNIVERSITY MEDICAL CENTER GRONINGEN, UNIVERSITY OF GRONINGEN

Introduction: The dynamical systems approach is increasingly adopted in performance analysis in sports. Mainly, the oscillatory behaviour of players in racket sports has been under investigation (Lames, 2006; McGarry et al., 1999; Palut & Zanone, 2005). However, team sports like rugby, basketball and soccer have not been subject of these analyses for various reasons. It is hypothesized that in soccer, attacking and defending is strongly coordinated between teams. Therefore, the aim of this study was to explore small-sided soccer games as a dynamical system by means of 2 collective variables, i.e. centroid position and surface area (Frencken & Lemmink, 2008). In addition, we tried to identify patterns in the development of goal-scoring opportunities through visual inspection.

Methods: Ten young male elite athletes (17.3 years ± 0.7) played three small-sided games (4-a-side plus goalkeepers) of 8 minutes on a 28x36 m pitch. Player positions were recorded at 45 Hz per player by means of innovative technology, i.e. local position measurement (LPM) system.

In total, three measures were calculated per team for the centroid position (forward/backward displacement, lateral displacement and radial displacement) and surface area (length, width and surface area). Correlation coefficients (r) were calculated for these measures to analyze coherence of time series data of both teams.

Results: Correlation coefficients of centroid measures were higher for the centroid position ($.57 < r < .95$) compared to surface area ($-.06 < r < .39$). Highest correlation coefficients were found for forward/backward displacement of the centroid ($r > .93$). For 10 out of 19 goals, a crossing of the centroid positions in forward/backward direction was present prior to the goal being scored.

Discussion: In this study, we analyzed small-sided soccer games from a dynamical systems perspective. Results indicate inphase oscillations for the centroid position. The strongest inphase pattern is found for the forward-backward displacement of the centroid position. Teams coordinate attacking and defending primarily in this direction. No specific oscillatory pattern was found for all surface area related measures. Although rules of these small-sided games were similar to 11 vs. 11, players behaviour is constrained differently when com-

pared to 11. vs. 11. This results in the absence of a clear pattern. Finally, we showed that deviations of the inphase pattern of centroid position indicate goal-scoring opportunities in small-sided games. We conclude that the small-sided soccer games can be considered a dynamical system and this approach opens up new types of analyses in performance analysis in team sports.

ASSOCIATION OF PERFORMANCE PARAMETERS OF PROFESSIONAL ELITE SOCCER PLAYERS THROUGHOUT THE SEASON

SILVA, J., MAGALHÃES, J., ASCENSÃO, A., SEABRA, A., REBELO, A.

FACULTY OF SPORT, UNIVERSITY OF PORTO

Introduction: The achievement and maintenance of an adequate level of physical fitness is a complex process, since adaptations to training and competition are specific to each individual. Thus, one of the central aspects of high performance training concerns the behaviour of the performance dynamics (Maia et al., 2001). Therefore, the purpose of this study was to analyze the association of soccer players' performance-related parameters throughout the season.

Methods: Twenty-two Portuguese elite professional soccer players were evaluated in four occasions throughout the season [prior pre-season (PPS), end pre-season (EPS), mid-season (MID) and end-of-season (EOS)] for counter-movement jump (CMJ), 5 and 30 m sprint (T5 and T30), agility (T-test), maximal concentric isokinetic knee extensor (KE) and flexor (KF) strength (90ºs-1), and intermittent endurance performance (YYIET2; no YYIET2 data were collected in MID due to Club match commitments). The association of soccer players' performance-related parameters throughout the season was analysed by the Pearson correlation coefficients (R).

Results: The SCM, T30, KE, KF and dominant leg hamstring/quadriceps ratio (H/Q-DL) R coefficients were high ($p<0.05$) between the different assessment moments (r ranging 0.7-0.9). In YYIET2, agility, and non-dominant leg H/Q (H/Q-NL) a lack of correlation between some season periods were observed ($p>0.05$). Concerning T5 performance, only a moderate correlation was found between PPS and MID.

Discussion: Although some parameters were sensitive to change throughout the season (SCM, H/Q-DL, YYIET2 and agility), there were differences regarding athletes' performance in the different moments. The SCM, T30, KE, KF and H/Q-DL tests had individual stability through the season, as observed by the high values of R between the different occasions. However, YYIET2, agility, H/Q-ND, and particularly T5, showed a high intraindividual variation throughout the season. This is particularly relevant as acceleration (Cometi et al., 2001) and intermittent endurance (Bangsbo et al., 2008) are essential variables to soccer high performance. Also, individual instability in H/Q ratio suggests that this parameter should be often controlled. In conclusion, data suggest that the continuous assessment of performance-related parameters throughout the season is a fundamental tool in the development of training programs suitable to the specificity of players' performance dynamics.

RHYTHMIC TRAINING AND PERFORMANCE IN FEMALE FUTSAL

IANNARILLI, F., BENVENUTI, C., DE PERO, R., AMICI, S., CAPRANICA, L.

UNIVERSITY OF ROME

Introduction: Futsal matches are characterized by fast passing, shooting, intercepting, dribbling and free for making actions. In particular, to get "free for marking" the players need very complex technical capabilities in choosing the proper timing to anticipate the opponent, and in selecting the appropriate field zone for correctly realizing the skill (Nuccorini, 2002). Rhythmic training proved to improve the locomotor and jumping abilities of children (Derri et al., 2001; Zachopoulou et al., 2004) and the technical abilities of young tennis players (Zachopoulou & Mantis, 2004). Thus, the aim of the present study was to evaluate the effects a rhythmic training on the "free for marking" capacity of female futsal players following a rhythmic training.

Methods: Sixteen female futsal players (25±5 yrs) involved in the Italian First League "Serie A" 2006-2007 Women's Futsal Championship participated in this study. They were equally divided in the experimental and control groups. For 16 weeks the experimental group performed a rhythmic training twice a week during which futsal drills with or without ball were performed according to the music. The exercises and music varied every two weeks. The ratio between the "free for marking" and the total performed actions during three-minute matches was used to evaluate the players' futsal ability. A video-analysis was performed at the beginning and at the end of the 16-week experimental period. ANOVA for repeated measures was applied to evaluate the differences ($p<0.05$) between pre and post training performances.

Results: At the end of the 16 experimental weeks, the experimental group significantly ($p=0.01$) improved the "free for marking" ability (pre=58±21%; post=67±9%), while no significant difference emerged in the control group (pre=58±21%; post=61±5%).

Conclusions

For a futsal player "free for marking" is one of the most important capabilities, often crucial to positively conclude the attacking actions (Nuccorini, 2002). The present findings showed that futsal players could benefit from a rhythmic training to improve this specific skill, which strongly rely on timing (Zachopoulou & Mantis, 2001).

EFFECT OF COMPLEX VS. REPEATED SPRINTS TRAINING ON REPEATED SPRINT ABILITY AND ATHLETIC PERFORMANCE IN YOUNG ELITE SOCCER PLAYERS

BUCHHEIT, M., BRUGHELLI, M., DELHOMEL, G., AHMAIDI, S.

FACULTY OF SPORT SCIENCES, UNIVERSITY OF PICARDIE, JULES VERNES

Introduction: Repeated sprint (RS) ability (RSA) is related to maximal speed and metabolic-related factors (e.g., PCr recovery, H+ buffering) (Bishop et al., 2004). RS training has been shown to improve RSA in adult soccer (Bravo et al., 2008) and adolescent handball (Buchheit et al., 2008) players. Nevertheless, the respective impact of a strength/speed (aimed at improving maximal speed) vs. a 'metabolic' (aimed at improving the ability to repeat sprints) training program is unknown. Thus the aim of the present study was thus to compare the effects of strength/speed vs. RS training on RSA in young elite soccer players.

Methods: Fourteen elite male adolescents (14.5±0.5 y; Tanner Stage III = 8, IV = 6; 64.1±7.7 kg; 1.77±0.9 m; 9 h.week-1 + 1 game) were assigned to either complex (C; n=7) or repeated sprint (RS; n=7) training groups. During 10 weeks; C consisted in 4 to 6 series of 4 to 6 exercises (e.g., counter movement jumps (CMJ), depth and plyometric jumps, agility drills, standing start and shuttle sprints), each repetition interspersed with at least 45 s of passive recovery; RS training consisted of 2-3 sets of 5-6 x 15-20 m shuttle sprints (interspersed with 14 s of passive or 23 s of active recovery [≈2 m.s-1 (Buchheit et al. 2008)]). The groups performed either C or RS once a week and maintained similar external training programs. Before and after training, performance was assessed by a CMJ, a hopping test (Hop), 10 and 30 m sprint times (10m and 30m), and best (RSAbest) and mean (RSAmean) times on a repeated shuttle sprint ability test (Buchheit et al. 2008).

Results: After training, except for 10m (P=0.22), all performances were significantly improved in both groups (all P<0.05). Relative changes in 30m (-2.1±2.0 %) were similar for both groups (P=0.45). C tended to induce greater improvements in CMJ (16.9±12.9 vs. 8.7±4.5 %, P=0.08, ES=0.9) and Hop height (27.5±19.2 vs. 13.5±13.2 %, P=0.08, ES=0.9) height compared with RS. In contrast, RS training induced greater improvement in RSAbest (-2.90±2.1 vs. -0.08±3.3 %, P=0.04) and tended to enhance more RSAmean (-2.61±2.8 vs. -0.75±2.5 %, P=0.10, ES=0.70) compared with C.

Conclusion

Both complex and repeated sprint training regimens represent effective means to increase physical performance in young elite soccer players. Nevertheless, changes in performance are likely training regimen-specific, with repeated sprint training being more effective at improving running performance (i.e., RSA) and complex training more effective at improving jumping ability.

THE EFFECT OF EXTERNAL RESISTANCE METHOD ON THE CHANGE OF ELITE FOOTBALL PLAYERS' SHOOTING SPEED

MALÝ, T., ZAHÁLKA, F., DOVALIL, J., MALÁ, L., HRÁSKÝ, P.

FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY PRAGUE

Introduction: Speed abilities belong to the most difficult trained abilities within coordination abilities and therefore it is necessary to look for such methods, means and forms that are effective for their development (Bompa, 1999). The research objective was to find out about the effect of external supplementary resistance usage on the speed of elite football players' instep kick and to find out possible changes in kinematical parameters of the kick.

Methods

All players were professionals (n = 8, age = 24,0 ± 4,7 years, height = 179,5 ± 4,1 cm and weight = 70,4 ± 5,1 kg). The sample was randomly divided into resistance group (RG) and control group (CG). Ankle weight resistance (0 % or 1 % from the body weight of player) was an experimental factor. The usage of ankle band weight was applied 2x / week in speed load, or in technical training focused on shooting. There was 383 minutes when training with ankle band weights totally, which means 8,09 % of total load 4732 minutes. We observed maximum speed of the ball after the kick and the chosen spatio-temporal characteristics of the kick. To gain data we used 3D kinematical analysis and radar device STALKER ATS. From evaluative methods we used ANOVA RM 2 x 2, Bonferonni correction for multiple average comparisons, effect size and magnitude of increasing (Thomas and Nelson, 1996).

Results: We discovered significant relation between interaction of both factors (time x resistance) $F(1,6) = 9.73$, $p < 0.05$, η2 = 0.40. The main effect of time was also significant $F(1,6) = 8.89$, $p < 0.05$, η2 = 0.36. The level of speed of the ball after the instep kick increased in RG from pre-test values (M1 = 31.62 m/s, SE1 = 0.69 m/s) to post-test values M2 = 32.73 m/s, SE2 = 0.88 m/s), $F(1,6) = 18.62$; $p < 0.01$. From the point of view of effect size evaluation, middle effect was discovered ESRG = 0.63. The importance of intervention increase is MOIRG = 3.51 %. The speed of the ball in CG did not show changes between pre-test values (M1 = 32.01 m/s, SE1 = 0.69 m/s) and post-test values (M2 = 31.99 m/s, SE2 = 0.88 m/s), $F(1,6) = 0.01$; $p = 0.93$. Regarding mater-of-fact significance there was no intervention effect indicated in the difference between averages of input and output values of speed of the ball when ESCG = 0.01 and importance of increase MOICG = 0.09 %. We did not find changes during evaluation of kinetic structure of the kick in any group.

Conclusion

It appears that the external resistance method may positively influence the shooting speed and the supplemented resistance is not terminal as the spatio-temporal characteristics did not change.

PERCEIVED STRESS AND RECOVERY IN OVERREACHED YOUNG ELITE SOCCER PLAYERS

BRINK, M., VISSCHER, C., LEMMINK, K.

UNIVERSITY MEDICAL CENTER GRONINGEN, UNIVERSITY OF GRONINGEN

Introduction: A disturbed balance between stress and recovery is considered to be the cause of overreaching. Monitoring the stress recovery balance might prevent athletes from symptoms such as fatigue and disturbed mood, eating and sleeping patterns (Nederhof et al. 2008). Since overreaching is characterized by sport-specific performance decrement (Meeusen et al. 2006), research is needed that relates measures of stress and recovery to performance decrement. Therefore, the goal of this study was to investigate if stress and recovery can be used as a tool to prevent overreaching in elite soccer players.

Methods: Stress, recovery and performance were prospectively monitored in 94 young elite soccer players during two competitive seasons. The Dutch version of the Recovery Stress Questionnaire for athletes (RESTQ-Sport) was used monthly to assess the stress-recovery state of players (Nederhof et al. 2008).

Performance was monthly assessed by means of a submaximal Interval Shuttle Run Test (Lemmink et al. 2004; Brink et al. 2009). Subjects with a heart rate increase ≥ 5 b•min-1 of four up to eight weeks were classified as overreached. A sports physician screened all subjects to exclude other causes of performance decrement.

Individual differences in perceived stress and recovery over the previous two months of eleven overreached soccer players and six controls were analysed (mean ± SD: Age (years) 17 ± 1, Height (cm) 176.56 ± 5.33, Weight (kg) 69.50± 6.06). Positive stress scores indicated increased stress, whereas negative recovery scores indicated decreased recovery.

Results: Mann-Whitney tests showed that there were no significant differences between overreached and control soccer players in general stress (mean± SD: 1.5 ± 4.0 vs. 0.5 ± 1.3), general recovery (-0.7 ± 2.1 vs. 1.2 ± 2.5), sport-specific stress (-0.1 ± 1.5 vs. -0.1 ± 0.3) and sport-specific recovery (0.3 ± 1.9 vs. 0.8 ± 2.6).

Discussion: The results demonstrate no differences in perceived stress and recovery between overreached and control soccer players. However, there is a tendency that overreached soccer players experience more stress and less recovery. The large standard deviation indicates that some players do not report changes in stress and recovery, despite performance decrement. Possible explanations are the relative young age of the players and different psychosocial awareness of team sport athletes. This should be kept in mind when using these subjective ratings.

WHAT DOES YOGA MEAN TO YOU?

HUATORPET, S.

HEDMARK UNIVERSITY COLLAGE

Introduction: In Norway, as elsewhere in the western world, there has been an increase in the number of people participating in yoga in recent years. Yet the reasons for the increase in popularity of yoga are unclear and this remains an under-researched area. Definitions of yoga embrace physical, psychological and spiritual notions of health and well-being and reflect a view of yoga as a way of life rather than simply a form of physical exercise. This suggests that there may be very many different reasons why people engage with yoga.

This small scale, qualitative research study set out to explore why yoga teachers engaged in the practice of yoga by exploring the meanings they attached to the activity.

Methods: Thirteen yoga teachers were asked to participate in the study by responding to the question: What does yoga mean to you? They were asked to write their responses down. Yoga teachers were chosen because they were likely to have established views on yoga through their commitment to their regular and frequent practice.

Results: Eight yoga teachers participated in the study. Their qualitative responses were analysed thematically in order to identify key themes in their narratives. Preliminary analysis revealed that yoga was important in their lives at quite a fundamental level. For example, participants linked their own personal development as something beyond themselves; as an offering to the rest of the world. Participants also gave expression to the view that it was an activity that related to their body, soul and mind and connected it to both physical and mental health. Furthermore, it was evident that yoga was seen in terms of transformation, elevation and liberation.

Conclusion: While it's obvious that yoga is essential and a big part of the lives for the yoga teachers, the next step will be to explore what yoga means to yoga students.

THE EXCELLENCE IN SPORT. A CASE STUDY OF A TOP-LEVEL VOLLEYBALL COACH.

PEREIRA, A., LEITÃO, J.

POLYTECHNIC INSTITUTE OF VISEU; UNIVERSITY OF TRÁS-OS-MONTES AND ALTO DOURO

Introduction: During the last years, the interest in studying the excellent coach has increased (Jones et al., 2002). Janssen & Dale (2002) and Orlick (2008) talk about some interesting topics, even though they deserve further research. This way, it becomes urgent to further investigate this issue, so that it becomes possible to gather more data concerning the coach's interpretation of his own professional

experience, the principles which guide his actions and the meaning of his behaviors (Jones, 2007; Jones et al., 2003). The aim of this study was to identify the values and the references that guide Professor Percy Oncken, a Brazilian volleyball coach and winner of various world-wide championships, in his work.

Methods: The research technique used was 'life stories'(Tierney, 2000). The data was collected by carrying out in-depth interviews and non-participative observation. The technique used for data analysis was content analysis (Strauss & Corbin, 1998). The computer programme of qualitative data analysis QSR NVivo 7 was used in coding the transcripts of the interviews.

Results and Discussion: Among the concerns that have followed his life-long career, we can highlight his great passion for his profession, respect for athletes and determination when facing difficulties. In terms of ambitions, we can point out the will to do his best every day and to one day train senior athletes. He regards difficulties that arise as being indispensable to a process of perfection. Having deprived his family of his attention is what has distressed him the most. The most important moments of his career were when he achieved good results and the ones that generate more suffering are those when he dismisses players from the national team. In terms of his social intervention, he is concerned with permanently carrying out his work with great quality and fully developing athletes.

FORMER TRACK AND FIELD EXPERIENCES INFLUENCE BEGINNERS' POLE VAULT LEARNING

VAGO, B., KOVÁCS, N., SZALMA, L., BENCZENLEITNER, O.

SEMMELWEIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES

Introduction: One of the key points beginner pole-vaulters must deal with is whether their dominant hand is in consonance with their opposite-side takeoff foot. This cross-dominance (CD) is an integral part of the vaulting technique. However, if an athlete is same-side dominant (SD), e.g., a right-handed athlete uses the right foot for takeoff in long/high jump, he has to either use the non-dominant hand for upper (dominant) grip on the pole, or execute the takeoff from the non-dominant leg. The objectives of this study were to gain information of the participants' subjective feelings about the effect of their former track and field experiences on the learning process, to investigate the learners' decisions on the bilateral hand/foot issue, and to highlight the chosen approach length of the run-up.

Methods

Ninety-one well-trained physical education university students (47 women and 44 men) participated in an eight-week/eight-lesson unit on pole vaulting. None of the subjects had previous experience in this event, but all of them were proficient in relevant track and field and gymnastic skills. During the lessons they participated in traditional learning drills, followed by commonly accepted short-approach (4-6-8-10 running strides) vault attempts, and finally, a short-approach pole vault competition (8-10 running strides).

Besides registering their vaulting results, a questionnaire was administer in order to find out the subjects' opinion about the relationships between their learning progression and initial motor skills in track and field and gymnastics, their decision on the dominancy of hand/foot, and their preferred approach length.

Results: By the end of the eight weeks the women averaged 2.10+-0.17m, men's average result was 236+-0.20m. Fifty percent of the subjects indicated that their former high jump experience had the greatest positive intertask transfer on their learning progression.

The long jump was named as the most important even by 38.9% of subjects. In addition, 83.3% of the subjects appointed jumping ability to be more important than gymnastic abilities. Twenty-three participants were SD, but only 4 reported difficulties choosing the takeoff foot-upper hand combination. Eighteen (78.3%) of SD decided to change their hand position and to do the takeoff from their long/high jump takeoff foot in order to obtain the proper technique, while 5 (21.7%) performed the takeoff from their non-takeoff foot. The majority of the subjects (61.5%) felt the 8 strides as the most effective length for their approach, while others (20.9% and 15.4%) preferred 6 and 10 strides, respectively.

BECOMING A GOOD COACH

HEMMESTAD, L., STANDAL, Ø.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Good coaching does not necessary mean good, in the sense of an effective and successful coach who receives good results. Good can also be viewed as doing what is morally right.

It is argued that sports coaching should be understood as an everyday encounter (Jones, 2007) where the practitioner is fully immersed in the activity. This emphasizes the importance of the coach reacting to situational events, which comprises flexible adoptions to cognitive anticipations and situational happenings.

Sports coaching then is viewed as a deliberate practice that is not only depended on facts and explicit coaching skills, but also of personal judgements and decisions. Both the ¨how to coach¨ text book recipes and much of the scientific knowledge which support coaches' work builds on a technical means-to-an-end thinking. In this case the coach becomes a ¨technican¨ expert. But, the means are not neutral but value-laden and therefore interaction in sports coaching is thus not a neutral process of applying means to ends, but should rather be viewed as a value-laden practice¨. For example considering a few examples:

1. In many instances, the coach makes decisions in an ethical twilight zone where the performance of the individual athlete and the team must be balanced with the well-being of the athlete.

2. Athletes are subjected to the coaches' power and they may go far in order to gain recognition and goods from the coach (e.g. sacrifice their future health).

In these examples there will be no formula that can tell the coach how to act. Rather, each situation calls for ethical judgements by the coach.

The Aristotelian notion of phronesis is useful in order to understand more clearly the ethical challenges involved in professional judgement in coaching. Phronesis is a form of practical wisdom that balances knowledge of universals with a sound appreciation of the particulars of each case (cf. Gallagher, 1992). The characteristic feature of practical rationality is judgement, which is a crucial aspect to take into account when you navigate within the complexities and context-dependent features that are in play in the messy sport coaching landscape.

We will discuss the relevance of phronesis to coaching, and ask if and how phronesis can be learned and practiced by coaches. For Aristotle practical knowledge in general and phronesis in particular can only be learned by taking part in the practice one is concerned with. This should suggest that for a coach phronesis could be learned through some form of apprenticeship in sports coaching, through following ¨the good example¨.

STUDY OF TIME DURATIONS: "THE TRAJECTORY OF THE BALL IN TEAM SPORTS AND HYPOTHESIS ABOUT ITS EFFECT ON PERCEPTION'

RAIOLA, G., AIELLO, P., SIBILIO, M.

UNIVERSITY OF CASSINO, UNIVERSITY OF SALERNO

Introduction: Sport teams have been the subject of various research concerning the quantitative aspects of performance, strength, endurance, speed, the technical aspects of gestures, biomechanics, motor control, qualitative tactical aspects as game scheme and the strategy as well as the educational issues for an appropriate teaching and training. We consider that these aspects can also help to build up a theory about training methodology in team sports. It has never been studied how the ball is touched by the body: grasp, throw, the reject of the ball and the time that it takes between two consecutive touches by two different players. These aspects have never been searched or tested on the game court although they are present in all team sports. This affects the dynamics of the game as well as the movement. Knowing how the ball is touched by the body and the relationship between the time and the space in different team sports is related to perception and its effects on training methodology.

Objective : Measuring the time displacement of the ball between two consecutive touched by two players including the contact time for different sport teams

Methodology : Video analysis of the matches of same rank. Performance analysis software and time measurement by statistics central index as mean and mode, comparing time distance and contact with ball in different team sports

Results: Volleyball has the first lower time, basketball has the second lower time, handball has the third lower time and finally football has the last time

Discussion: Rejection is a very fast movement , the fastest one among those that are usually performed in team sports. The information is taken and processed in mind very quickly and the response must be equally fast. The small size of the playing field decreases the time with which the ball moves.

Conclusion : In order to correctly analyze the phenomenon, it is required to deepen the main theories on motor control. We need to take into account perception, aspects and include team sports training methodology.

GYMNASTICS ACTIVITIES: A PROPOSITION OF ACTIVITY PHYSICAL ABOUT TO CHILDREN OF 4 THE 6 YEARS OLD

NABEIRO MINCIOTTI, A., OBARA, M.L.B., VOLPI, M.M., SOUZA, S.P., SANTOS, T.V., MAIO, L., GARE, T.R., ARAÚJO, L.M., SÁ, C.S.C.S.

UNIVERSIDADE MUNICIPAL DE SÃO CAETANO DO SUL

Introduction: The infancy is the period what the child develops at every the dimensions (motor, physics, affective, social or cognitive). The quality from the experiences lived by children this period they'll determine of certain forms, the adult on which they if they'll become. The gymnastics activities are practices beneficial about to the persons at every the period of life. On first infancy they contributory on encouragement and development from the body movements and the functions all-important, just as on skill control and body dominate in different situation and on acquisition of standards basic of movement. Owing to the multiples factors what can step in on performance motor of jobs of life diary, it works and/ or activities sporting realized for children this study object observe the influence from practice of gymnastics activities into the development motor of children among 4 the 6 years old.

Method: Twenty eight children between 4 and 6 years old, both the types from community of São Caetano do Sul have been appraised based on the Protocol of tests of balance and coordination (Lefêvre, 1976). After the appraisals initial the children they performed the practice gymnastics twice a day week with one hour of duration each class for 3 months. The practice gymnastics offers activities focused about to the development from the capacities physics, skills manipulativas and the parts gymnastics (stars, rolls, forwards, backwards, round off, flic flac, among another). The finish from the 3 months the children have been reappraising. For each test, observed the success or failure comparing the two appraisals.

Results and Discussion: The tax of success on the tests of balance static and dynamic was of 70% initially at every the ages, inferior the 75% description for Lefévre (1976). After the practice gymnastics observed 100% of success on the states tests for all the ages. The results indicates the importance from activity physical into the daily from the children for the purpose of develop the capabilities physics , skills manipulativas and bring up a lifestyle more healthy for the child.

A PROGRESSIVE APROACH TO MAP COMMUNICATION WITH CHILDREN - THE USE OF HAND-DRAWN MAP

GRÆSLI, J.A., BJERVA, T., SIGURJÓNSSON, T.

HEDMARK UNIVERCITY COLLEGE

Introduction: The ability to interpret map symbols and understand the relationships between maps and terrain is to a high degree a complex activity. It includes a number of sequences of processes that have not sufficiently been explored (Keates, 1996, Sigurjonsson, 2007). Progress in education within this topic has not sufficiently been based on how children can benefit from different maps. (last sentence difficult to intgerpret)

Methods: The results presented in this context ARE quantitative data related to the use of EMIT (electronic timer system). The task was to find 7 controls on the basis of a hand-drawn map. The children should decide in what order they would find the controls. The study involved 106 children, 53 boys and 53 girls, aged 5 to 12 years. The selected area was near a primary school. None of the children in the study were pupils at this school. This paper grew out of a larger project which includes both other quantitative data and qualitative data through participatory observation, where the children were shadowed in the terrain.

Results: Among 5-year-olds 17 out of 41 children found all the 7 controls. Furthermore 21 out of 30 children in lower primary school, and 26 out of 28 children in upper primary school completed the task. In the group with 5-year-olds who mastered the task, we find no clear strategies in relation to the order in which controls are found. Among pupils in lower and upper primary school, the results show that the children to a greater degree considered appropriate route choices. Among 5-year-olds who mastered the task, There are 47% boys and 32% girls. In the lower primary stage 85% of girls and 65% of boys mastered the task and on the upper primary stage there are no gender differences.

Discussion: The results show that children far down in the age group mastered expected complex tasks when they where presented with simple aids (Blades & Roberts, 2000, Sigurjónsson, 2007). The difference from the youngest children to the older is that a greater proportion of the older kids master the task. The data indicate an incremental development in mastery of the task. From 5 to 6 years there is a clear decline, while there from 6 to 8 years are no significant changes. Similarly, there is a clear distinction between the 8-year-olds and the 10-year-olds, while there are no differences between 10-year-olds and 12-year-olds. The results show minor gender-related differences among the smaller children.

A PROGRESSIVE APROACH TO MAP COMMUNICATION WITH CHILDREN - THE USE OF DETAIL-PHOTO

BJERVA, T., GRÆSLI, J.A., SIGURJÓNSSON, T.

HEDMARK UNIVERSITY COLLEGE

Introduction: The ability to interpret map symbols and understand the relationships between maps and terrain is to a high degree a complex activity. It includes a number of sequences of processes that have not sufficiently been explored (Keates, 1996, Sigurjonsson, 2007). Progress in education within this topic has not sufficiently been based on how children can benefit from different maps.

Methods: The results presented in this context are quantitative data related to the use of EMIT (electronic timer system). The task was to find 10 controls on the basis of detail-photo distributed in two sets of 5 photoes. The first set was assumed easier, and the controls were initially closer. The study involved 106 children, 53 boys and 53 girls, aged 5 to 12 years. The selected area was near a primary school. None of the children in the study were pupils at this school. This paper grew out of a larger project which includes both other quantitative data and qualitative data through participatory observation, where the children were shadowed in the terrain.

Results: Boys (5-year-old) using on average 67 seconds to find the controls in the first set and 90 seconds in the next. The girls are using respectively 65 and 97 seconds. For boys and girls who are 6-year-old, the time has decreased to 39 and 42 seconds on the first set, and 67 and 64 seconds on the next. 8-year-old uses 37 and 67 seconds (boys) and 38 and 64 seconds (girls). The 10-year-olds have decreased the time to 21 and 33 seconds (boys) and 24 and 32 seconds (girls). Finally 12-year-olds uses 20 and 30 seconds (boys) and 24 and 30 seconds (girls). The boys in total spent an average of 37 (set 1) and 58 seconds (set 2). The girls spent an average of respectively 38 and 57 seconds.

Discussion: The results show that children far down in the age group mastered expected complex tasks when they where presented with simple aids (Blades & Roberts, 2000, Sigurjónsson 2007,). The difference from the youngest children to the older is consumed time per task. The 5- year-old spend, on average, nearly twice as much time in relation to pupils in the lower primary school. Pupils in the upper primary school using additional third less time per. task than the pupils in the lower primary school. The data indicates an incremental development in the time spent per. control. From 5 to 6 years there is a clear decline, while there from 6 to 8 years are no significant changes. Similarly, there is a clear distinction between the 8-year-olds and the 10-year-olds, while there are no differences between 10-year-olds and 12-year-olds. The results show no gender-related differences.

THE QUALITY OF TEACHING GYMNASTICS IN THE 7 TO 9TH GRADES OF ELEMENTARY SCHOOLS IN SLOVENIA

BUCAR PAJEK, M., CUK, I., KOVAC, M., PAJEK, J., TURSIC, B.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

In Slovenian elementary school curriculum, the gymnastic contents of physical education (PE) are defined. The aim of our study was to assess quality of the implementation of gymnastic curriculum at the PE in the last three years of elementary schools.

One houndred fourty-seven PE teachers involved in active teaching in the study year 2004/2005 were recruited to the study. The selection of recruited PE teachers was representative for Slovenian population. They were instructed to answer the questionnaire with 25 questions

divided in 4 main topics: socio-economical indexes, opinions about curricular gymnastic contents implementation, opinions about the work at specific school and opinions about minimal and optimal conditions for teaching gymnastics. Three and five point Likert's gradation was used to grade the answers. Also, there were yes/no questions and questions of the open type (a written answer) present in the questionnaire.
The majority of PE teachers expressed highly positive opinions about the presence of gymnastics in the physical education curriculum: they believe it is important and of positive impact for the psycho-physical development, it helps develop the sense of altruism, persistence and creativity and encourages mutual assistance, and it does not induce aggression. Despite this, teachers in average only performed 9.8 hours of gymnastics (out of 70 hours total per year) predominantly without performing the full curricular gymnastic content with pupils. Teachers ascribed the low rate of full gymnastics content realisation to poor material conditions, insufficient pupils' physical fitness and inappropriate curriculum (inappropriate gymnastic elements). According to the questionnare results, all these factors came before the teacher-dependent reasons (knowledge, motivation, lack of confidence at assisting with gymnastic elements).
According to this results, we conclude that there are diverse and numerous reasons for insufficient gymnastic teaching in elementary schools. Only in part could this problems be solved with a better continuing PE teachers' education and motivation. Especially as regards to the insufficient pupil physical fitness it is a fact, that they are often the consequence and not the reason of inadequate PE curriculum implementation. However the material conditions could also be improved to better perform the gymnastic contents of the curriculum.

SWIMMING ABILITIES ARE NOT ENHANCED BY USING A FLOTATION SUIT FOR ADVANCED BEGINNERS IN DEEP WATER SWIMMING TEACHING

KJENDLIE, P.L.
NORWEGIAN SCHOOL OF SPORT SCIENCE

Introduction:
There are few empirical data on the effect of using flotation aids in swimming teaching. Flotation aids, such as body suits - giving extra buoyancy, may have advantages: a safer child, more able to do exercises on their own, independently of the teacher, and possibly increasing the activity level. Disadvantages of using flotation aids in general are that children become dependent on the aid, not learning to float free and independently, and that self confidence of learning to swim unaided is not developed.
Purpose: The purpose of this study was to investigate the effect of wearing a flotation suit on swimming, arm stroking and leg kicking performance of children in a learn-to-swim program.
Methods: Ninety-nine (99) children, with previous swimming school experience, but not yet able to swim, were taught swimming once a week for ten weeks. Each group were randomised to use flotation aids (FL, n=40, mean age 7.4±1.1 years) in the form of a flotation suit, or to not use the suit (CON, n=59, mean age 7.4±1.0 years). The reported previous beginner-swimming teaching experience was 3 or 4, 10 hour courses for the CON or FL respectively ($p<0.03$). FL did also exercises at the end of each lesson without the suit to enhance their unaided abilities. Their skills after 10 lessons were observed through video recordings, using a modified Aquatic readiness assessment test (Langendorfer and Bruya 1995) with tagging of events in the Dartfish software. Combined swimming, leg kicking, arm recovery and arm propulsion were evaluated on a score ranging form 1 (no performance) to 5 (advanced skill). Additionally the leg kicking velocity was measured both pre and post intervention by use of a swimming velocity meter.
Results: The mean scores were for combined swimming 3.0±0.6 and 3.1±0.9, arm propulsion 2.6±0.5 and 2.7±0.5, arm recovery 2.2±0.7 and 2.3±0.7 and leg kicking actions 3.4±1.0 and 3.5±0.8 for FL and CON respectively (NS). Leg kicking velocity improvement (pre to post test) were 0.03±0.1 and -0.03±0.3 m/s for FL and CON respectively (NS). The inter observer reliability for combined swimming abilities were 86% exact agreement, and a Chronback's Alfa coefficient for reliability using the 4 skills were 0.87.
Discussion and Conclusions:
The results show that for none of the four skills, no statistical differences in performance existed after a 10 lesson course using a flotation suit compared to the control group. This finding is supported by the leg kicking speed measurements where there were no differences in improvement for the two groups. The results does thus not support a hypothesis of enhanced effect of using a flotation suit during swimming teaching for advanced beginners in a deep water setting.

PP-RE01 Rehabilitation 1

EFFECT OF THE WII SPORT BOXING VIDEO GAME ON HEART RATE IN CARDIAC PATIENT.

BLANC, P.
CENTRE DE REEDUCATION SAINTE CLOTILDE

Physical exercise is an important part of the rehabilitation (CR) program in cardiac patients. The new generations of active video games allow performing various recreational sport activities at home. However, the cardiac impact of virtual sport activities has been poorly investigated.
The purpose of this prospective study was to analyze the heart rate (HR) response of cardiac patients while playing a commercially available gaming system: Wii sports boxing game software.
27 voluntary patients (5 women, 22 men, mean age 50.6 +-13.3 years old) were included in the study after completion of a 6 week cardiac rehabilitation (CR) program. Causes of admission in CR were: percutaneous transluminal angioplasty (33%), coronary artery bypass grafting (19%), valve replacement (15%), dilated cardiomyopathy (11%), other (22%). Patients performed an exercise testing (ET) with gas exchanges measurement at the end of the CR program and before playing video game. The exercise testing allowed the determination

of the ventilatory threshold HR and the maximum HR. Participants played competitive boxing matches for 15 minutes, as recommended by Nintendo, with a five minute warm up. HR was recorded using a polar system (S610i) whilst playing Wii sports boxing and compared to ET measures. All participants had not previously used Wii and consented to the study.

During virtual sport activity, mean HR was 106+/-25 bpm and maximum heart rate was 190 bpm. Throughout the HR recordings, 49 +- 35 % of the game (8.24 min +- 6.22) was performed with a HR above the ventilatory threshold HR (107.0 +/-17.6 bpm). Finally, HR was higher than the ET maximum HR during 9% +- 16% of the game (1.52 min +-3.22).

Conclusion: In this preliminary study, the main part of the Wii sports boxing game lead to an HR above the anaerobic threshold, implying an important demand on anaerobic metabolism. Consequently, caution should be recommended to cardiac patients before playing virtual sport activities on video game.

THE IMPORTANCE OF THE CARDIOLOGY PREVENTION AND REHABILITATION IN THE MIRROR OF AN EXPERIMENTAL PROGRAM

NOÉ, J., DÓSA, A., PAVLIK, G.

SEMMELWEIS UNIVERSITY BUDAPEST AND UNIVERSITY OF PANNONICA AND FOURMED LTD VESZPREM

Introduction: Unfortunately there's a rising tencency in our contrys int he cardiology particulalry illnesses following previal (obesitas, DM, etc.). The curing three of its keystones, the classic triple partition is becoming interwoven (prevention, curing, and rehabilitation) today already it's a new thought. Though particulalry the prevention has the importance to call the attention, since the preventions possibly the most effective mannee for the rehabilitation.

Methods: The filtration, prevention, kinesitherapy present the opportunities of the linking of a treatment and aftercare in FourMed Ltd and program drawn up by the colleagues of PE Department University of Pannonica. Inside the framework of this the patients after he filtration (anamnesis, calmness and load examination with a bicycle Ergoline, with the Bruce protocol, risk factor research, then regular medical check) are collaborating whit the therapists actvely individuals, continuosly monitoring kinesitherapy trainings are made.

Results: For the most important result int he program because of the beginnings had bought the considerable improvement of the values of one (two years observing, weekly 3-4 times 45-60 minute trainings making his case) may consider, but very important to mention this finding, the forming of ther lifestyle, their health-conscious behaviour to the new patients optimal motion program, on which longer distance the decrease of the risk factors, easier stress treatment and –may serve having patience, calmer manner of living.

Summary: The improvement of the oxidative capacity at the weekly ones training 3 times under 5 weeks 50% was (rel.VO2 before a training 26,5, after a training=39,7 ml/kg/min). Who made an aerobic training two times weekly, 35%-kal the result was right. A calmness pulse and the blood pressure values improved. The patients reported on calmer sleep and the easier solution of the stress situations. Their better Latvian general general condition and their metabolism accelerated, the calorie input and consumption returned to normal. The anxiety decreased, the creativity increased. The parasympathetic tone and HR intensified variability, because decrease the risk of the sudden heart death.

Of the distinguished opportunities reduction of the cardiovascular risk factors the pulse control with the POLAR watches and personalprogram with aerobic (cardio) training, at least weekly 2-3 times, in an optimal case with 4-5 times weekly. Finally it's worthy to deliberate the economic viewpoints, believes for example the society gets reimbursed for each single dollar spent on this sixfold int he USA.

VARIATIONS IN ISOKINETIC STRENGTH LOSS FOLLOWING PLYOMETRIC EXERCISE

TWIST, C.

UNIVERSITY OF CHESTER

Introduction: A reduction in maximal voluntary isometric force is considered to be one of the most appropriate indirect markers of exercise-induced muscle damage (EIMD) (Warren et al., 1999). Although isometric force loss is known to demonstrate large between subject variations following eccentric-biased exercise (Hubal et al., 2007), the variations in isokinetic strength loss are less clearly understood. Furthermore, there is little known about the inter-subject responses to force loss induced by modes of eccentric-biased exercise commonly adopted in athletic training. Therefore, the purpose of this study was to investigate the variations in isokinetic strength loss following plyometric exercise.

Methods : Following ethical approval, 16 participants (age 21.9 ± 2.4 y, stature 1.76 ± 0.1 m, body mass 70.6 ± 11.2 kg) volunteered to participate in the study. Participants were recreationally active and had no history of resistance training in the previous 6 months. Peak isokinetic torque of the knee extensors was measured at 60 deg/s. In addition, perceived muscle soreness was recorded on a 0–10 visual analogue scale. All measurements were taken before and then at 24 and 48 h following 10 x 10 countermovement jumps. A cluster analysis of peak torque data at 48 h was used to objectively establish high (HR) and low responders (LR) to plyometric exercise.

Results: At baseline isokinetic strength was not significantly different between HR (n = 6; 207.9 ± 12.9 N•m) and LR (n = 10; 168.8 ± 20.2 N•m) (P>0.05). Although there were no differences between groups in body mass or age (P>0.05), stature was significantly higher in the HR group (t = -2.847, P<0.05). Moreover, sex distribution between groups was different (LR: 67% females cf. HR: 10% females). Consistent with the objective grouping, there was a significant group by time interaction for peak isokinetic torque (F=78.1, P<0.05). Reductions in isokinetic peak torque for HR was 22% (range 17-34%) and for LR 7% (2-14%). However, there was no difference in perceived muscle soreness between groups represented by the non-significant group by time interaction (F = 0.173, P>0.05).

Discussion: The results suggest that inter-subject variations in isokinetic force loss occur following plyometric exercise, even though no differences exist between HR and LR in the subjective markers of perceived muscle soreness. However, sex distribution might explain some of the observed variations, with a larger proportion of males in the HR group. In addition, the magnitude of relative force loss appears to be lower for both HR and LR compared to those previously reported for isometric strength (Hubal et al., 2007).

CONTRALATERAL CHANGES IN RANGE OF MOTION FOLLOWING UNILATERAL PROPRIOCEPTIVE NEUROMUSCLAR FACILITATION STRETCHING.

SHEARD, P.W., PIEROZYNSKI, L.C., PAINE, T.J.
UNIVERSITY OF BEDFORDSHIRE

Background: Carrol et al.'s (2006) meta-analysis indicates that unilateral resistance exercise will elicit strength gains in the unexercised contralateral limb at about 50% of the gains measured in the exercised limb. They suggest two forms of increased motorneuron output as likely routes to this contralateral gain: "spillover" from the central control mechanisms from the exercised to the unexercised limb; and, adaptations in the exercised limb that may be "accessed" by the unexercised limb. The present study was undertaken to test the hypothesis that the spillover effect may be present in proprioceoptive neuromuscular facilitation (PNF) stretching techniques allowing for contralateral gains in range of motion (ROM) from unilateral PNF stretching.

Methods : Thirty-six screened participants (F = 15) attended a familiarization and MVIC testing session and two, counterbalanced, experimental sessions. One experimental session consisted of the application of post-isometric relaxation (PIR) PNF: straight leg raise (SLR) to first point of bind, build from 30 to 70% of MVIC over 5 seconds, hold 70% MVIC for a further 7 seconds, draw to new point of bind, hold for 12 seconds; repeat cycle a further 2 times. Isometric contractions were resisted by an anchored strap with a strain gauge in-line for real-time %MVIC feedback. The second experimental session consisted of 3 unresisted SLR to point of bind, 24 seconds apart. ROM of both limbs were measured using a liquid goniometer pre-intervention and after each of the three experimental cycles. EMG was measured in the homologous muscle of the contralateral limb to measure level of concurrent (in)activity.

Results: Three participants were excluded from analysis: 1 due to injury and 2 due to EMG signals in excess of 2 SD above baseline, indicating concurrent contraction. No significant changes ($p = 1.000$) were found in the ROM of either limb for the unresisted SLR session. The limbs that underwent the PIR-PNF protocol showed significant increase in ROM (mean diff = 11.2 degrees; $p < 0.0001$). A lesser, but still significant, increase in ROM was also seen in the 'dormant' contralateral limb (mean diff = 5.9 degrees; $p < 0.0001$).

Discussion: The significant change in ROM in the unstretched contralateral limb indicates that some degree of neurological crossover had occurred. This may indicate a spillover of: GTO induced relaxation; suppression of muscle spindle fibre activation; and/or, alterations to the participants' stretch perception. These findings may have application in rehabilitation settings where stretching of one limb may be restricted by injury; some degree of flexibility may be maintained, decreasing the time necessary to return to full ROM once the injury has healed sufficiently to undertake direct rehabilitation.

THE INFLUENCE OF AGE-RELATED CHANGES IN TACTILE SENSIBILITY AND MUSCULAR STRENGTH ON HAND FUNCTION IN OLDER ADULT FEMALES

MURATA, J., MURATA, S., HIROSHIGE, J.
GRADUATE SCHOOL OF BIOMEDICAL SCIENCES, NAGASAKI UNIVERSITY

Introduction: The effects of aging on motor function include a marked decline in strength and muscle mass, leading to impairments of mobility and activities of daily living. Aging also affects human hand function. For example, a decline in manual dexterity often accompanies old age. This decline corresponds to age-related changes in muscle and/or tactile functions. This study investigated whether age-related changes in muscular strength and tactile sensibility are related to hand function in older adults.

Methods: The subjects were 49 older adult females (young-old, 27 females, 68.8 ± 3.7 years; old-old, 22 females, 80.2 ± 3.0 years). Hand function was assessed using the Perdue pegboard test. Handgrip strength was measured using a handgrip dynamometer. Tactile-pressure threshold on the distal palmar pad of the index finger was evaluated using Semmes-Weinstein monofilaments.

Results: Scores on the Perdue pegboard test showed significant differences between the two age groups ($p < 0.01$) and decreased with age. Tactile-pressure threshold was augmented with increasing age ($p < 0.05$), whereas handgrip strength did not differ between the two age groups. There was a significant relation between the Perdue pegboard test score and tactile-pressure threshold ($r = -0.513$), but not handgrip strength ($r = 0.255$).

Conclusions: These results suggested that manual dexterity in hand function was attenuated with increasing age. We considered that this attenuating effect was associated with a decline in tactile sensibility rather than a change in the muscular strength of the hand.

INFLUENCE OF LEG AND HIP STRENGTH ON LOWER BODY INJURIES IN ELITE SNOWBOARDING

PLATZER, H.P., RASCHNER, C., PATTERSON, C.
UNIVERSITY OF INNSBRUCK

INTRODUCTION: The overall injury incidence was 1.3 injuries per 1000 runs in the snowboarding FIS World Cup season 2002/2003 (Torjussen and Bahr, 2006). The most common injury location was the knee (18% of all acute injuries). Physical fitness is important for snowboard performance (Platzer et al. 2009), and could be a factor in injury prevention. The aim of this study was to determine the influence of different leg strength parameters on lower body injuries in elite snowboarders.

METHODS: 27 elite Austrian snowboarders took part in this study. The subjects mean values±SD for age, height and body mass were 24.1±4.8 years, 172.6±8.3 cm and 67.1±10.3 kg. All injuries in the season 2007/2008 were recorded during an interview. Concentric and eccentric leg/hip strength and power for flexors and extensors were measured on a Contrex leg press (closed kinetic chain). For statistical analysis t-tests were used to investigate differences between injured and non-injured athletes and to analyse the variation of strength and power between left and right leg/hip. A Phi test was used to correlate gender and standing position with the occurrence of injuries.

RESULTS: In the comparison of front and back legs, all athletes' back legs had greater absolute and relative eccentric strength and power ($p<0.01$) and lower H/Q-ratios ($p<0.05$). The back legs of the injured group were weaker in relative leg/hip extension ($p<0.05$) and had higher H/Q ratios than the non injured group ($p<0.05$). Injured athletes showed higher bilateral asymmetry in concentric leg/hip exten-

sion (p<0.01). There were no group differences in test front leg variables or in leg flexion (p>0.05). The Phi test did not show any correlation between gender (Phi=-0.031, p>0.05) or standing position (Phi=0.324, p>0.05) with lower body injury rate.

DISCUSSION: The results indicate that relative leg/hip extension strength may be important in the prevention of lower body injuries. Eccentric strength is important in the compression phase of the turn in slalom and giant slalom and landings in freestyle and snowboard cross events. The H/Q ratios in the injured group were better, but this could be due simply to the fact that the injured group was weaker in extension and similar in flexion strength. Athletes in alpine sports such as snowboarding and skiing typically have strong quadriceps and often neglect hamstring training. In conclusion, relative leg/hip strength and bilateral leg strength balance are beneficial in preventing lower body injuries.

PROPELLING EFFICIENCY IN MASTER SWIMMERS

ZAMPARO, P., MASSEI, E., GATTA, G., BENELLI, P.

UNIVERSITY OF VERONA

INTRODUCTION. When the swimming records in master competitions are evaluated, it becomes apparent that performance (e. g. maximal speed, vmax) decreases steadily as a function of age. In Italian front crawl swimmers the decrease is of about 0.2 m/s every 10 years of age in short distance (50 m) races and of about 0.1 m/s every 10 years of age over long distance (800 m) races. AIMS. The aim of this study was to investigate if this decrease could be related to a decrease in the propelling efficiency (ηP) of the arm stroke. This work stems from a previous study [1] where this parameter was investigated in children and adults (9-59 yrs of age) of good technical skill but where the adult swimmers were not attending master competitions. SUBJECTS. 61 male master swimmers were tested. They were divided into 4 classes of age: M1: 20-29 yrs (25.9±3.2, n = 17); M2: 30-39 yrs (34.8±2.7, n = 22); M3: 40-49 yrs (44.3±3.1, n = 12); M4: 50-59 yrs (54.1±3.0, n = 10). No major differences in the anthropometric characteristics were found in these subjects even if stature tended to decrease (1.81 vs. 1.77 m) and body mass to increase (72 vs. 78 kg) from M1 to M4. PROTOCOL. The subjects were asked to swim a 25 m pool length at constant speed and to repeat the swim at six different, incremental speeds (from slow, to moderate, to maximal). During each trial, average speed (v) and stroke frequency (SF) were measured in the middle 10 m of each lane. The distance per stroke (DS) was calculated from the ratio v/SF and ηP was estimated according to the simple model proposed by [2], on the basis of values of v, SF and of the shoulder to hand distance. RESULTS. The values of v (1.48, 1.42, 1.34, 1.06 m/s), SF (0.87, 0.86, 0.85, 0.69 Hz) and DS (1.74, 1.70, 1.61, 1.52 m) attained at vmax (in M1, M2, M3 and M4, respectively) show a steady decrease as a function of age. In M1, M2 and M3 both DS (1.9-2.0 m) and ηP (0.28-0.30) show a plateau at slow to moderate speeds whereas in M4, DS and ηP show a continuous decrease with increasing speed and are, even at their top (1.7 m and 0.23, respectively), lower than in the other classes of age. DISCUSSION. Between 20 and 50 yrs, ηP at vmax decreases of about 2% per decade (the decrease in vmax is similar: about 3% per decade). Between 50 and 60 yrs, ηP decreases to a larger extent (about 14%) yet less than the decrease in vmax (about 21% in this decade). This suggest that in masters up to 50 years of age the decrease in performance can be essentially attributed to a decrease in propelling efficiency but that, after this age, also other factors should be taken into account to explain the decrease in swimming performance.

COMPARATIVE METHOD TO ESTIMATE PROPELLING ABILITY

KARSAI, I., SILVA, A., GARRIDO, N., LOURO, H., LEITAO, L., MAGYAR, F., ÁNGYÁN, L., ALVES, F.

UNIVERSITY OF PÉCS

INTRODUCTION: Producing propelling force in an efficient way in the right swimming direction is one of the key factors in competitive swimming. During the action the extremities of the swimmer give energy to the water molecules to accelerate them, to generate flow around and along the hand-arm complex to achieve the highest pressure difference in the right time and space. There are differences in morphological and physical characteristics between swimmers and there is an infinite number of possible motion variations to perform the crawl arm stroke. Difference should exist between swimmers, and in the way they can exploit the potential of the fluid environment. Direct force measurement is impossible during free swimming and the analitical investigations up to date did not provide a useful method to calculate the force production, therefore a special approach is necessary to express the level of the propelling ability.

METHODS: 8 internationally recognised male swimmers (19,8 ±0,9 yrs, 73,9 ±6,0 kg, 181,7 ±5,5 cm) were asked to perform the non-breathing, only arm task on a special device which recorded the force (f=200). The legs were tied and supported. The starting frequency (FR) was set at f=0,5 Hz and was increased with f=0,083 Hz steps till the swimmer could maintain the stabil rhythm. 4 underwater cameras (50 Hz) were used to record the kinematic parameters and the APAS system was employed to calculate the 3D data for the analysis. Reference forces were calculated based on anthropometric and kinematic data with a 3-segment simple model concerning the drag equation without the C value and a projection to the swimming direction were related to the measured force data. The Pearson correlation was employed between the 100m sprint velocity and the result to test the suitability of the method.

RESULTS: The main force at the starting FR were 50,6 ±21,9 N. The force production increased almost in a linear fashion and peaked at the f=0,65 Hz: 76,2 ±24,5 N and dropped considerably at the highest FR value. The ratio between the measured and the reference force

at the starting FR: 2,04 ±0.68 the value is almost constant for the individuals across the FR increments, with a little peak around the 3rd step. Free swimming velocity was measured in 100m distance v=1.92 ±0.07 m/sec. The study showed significant correlation between the calculated ratio and the velocity swam in 100m (r=0.749, p<0.05).

DISCUSSION: The measured force difference caused by the unsteady effects of this dinamic experimental setup showed a litle higher value as it was reported by other experimental and analitical studies (CFD), where the quasy-steady and unsteady effects were investigated.

The result indicates that this method fits the requirement to estimate the propelling ability of individuals, whereas the result can provide the magnitude which can differentiate between swimmers but not the way they do it.

DOES THE KICK FREQUENCY AT THE SURFACE AFFECT THE PHYSIOLOGICAL RESPONSES IN INTERNATIONAL MONO-FIN-SWIMMERS ?

VERCRUYSSEN, F., BOITEL, G., BOURDON, L., BRISSWALTER, J.

1. UFR STAPS, UNIVERSITÉ DE TOULON-VAR, LA GARDE, FRANCE, 2. IMNSSA, HÔPITAL ST ANNE, TOULON, FRANCE

Introduction: The criteria which determine the relationship between the energy demand and the movement pattern in terrestrial activities depend strongly on the locomotion mode (Cavanagh & Williams, 1982; Marsh & Martin, 1997). In the context of aquatic locomotion, a great fraction of the energy demand is utilized to overcome drag. In monofin-swimming during which the subject produces continuously local forces during up and down movements at the surface from his fin, it has been hypothesized that one of the variables on which swimmers can work for improving performance is the kick frequency (Nicolas et al., 2007). The large variations of this parameter might affect the propelling characteristics at the surface and thereby, the drag and the associated energy demand. The objective of this study was to evaluate the effect of kick frequency on the energy demand and physiological responses induced in monofin-swimmers of international calibre.

Methods: Eight international monofin-swimmers (mean age: 18 ± 2.5 yr; mean weight: 70.5 ± 9 kg; mean height: 171 ± 8.8 cm) completed two testing sessions in a 50-m outdoor swimming pool. The first session consisted of a maximal test performed on a distance of 600-m in order to determine the oxygen uptake at the end of exercise (i.e. VO2 600m) but also, the mean speed obtained on the test (V600m). The second session was performed at a constant swimming intensity of 90% V600m composed of five bouts at different kick frequencies (600m exercise, 3-min rest). The first bout was systematically conducted at the freely chosen kick frequency (FCKF) and the other bouts (FCKF-15%, FCKF-10%, FCKF+10%, FCKF-20%) were presented in a random order. During the incremental and constant conditions, gas exchange was measured breath by breath with a portable system (K4b2, Cosmed, Rome, Italy) connected to a snorkel (Aquatrainer; Cosmed).

Results: Mean values for oxygen uptake (Vo2) were significantly reduced at FCKF+10% compared to FCKF-15% and FCKF-20%. However, no significant variations in heart rate (HR), ventilation (VE) and blood lactate concentrations ([La-]b) were observed between the conditions.

Discussion: The main results of this study indicated that the kick frequency selected by elite monofin-swimmers affects the energy demand during a constant swimming trial. Interestingly, the reduction of VO2 observed at the FCKF+10% suggests that the organisation of the movement pattern is different than those induced in terrestrial activities (e.g. Cavanagh & Williams, 1982; Marsh & Martin, 1997). Given the lack of significant variations in ventilatory parameters among the conditions, the differences in energy demand between the FCKF+10% bout and sub-frequencies might derive from different intrinsic muscular mechanisms.

CORRELATION BETWEEN OXYGEN UPTAKE KINETICS IN SEVERE INTENSITY SWIMMING AND ENDURANCE PERFORMANCE

REIS, J., ALVES, F., VLECK, V., BRUNO, P., MILLET, G.P.

FACULTY OF HUMAN KINETICS, LISBON

Introduction: Faster O2 kinetics has been associated with a lower O2 deficit and greater tolerance to fatigue but it is unclear whether it is a determinant of endurance performance. This study investigated the relationships between VO2 kinetics parameters within constant load severe intensity swimming, and 400m swimming performance.

Methods: Fourteen national level Portuguese swimmers (age 20.5 ± 3.0 yr.; mass 75.4 ± 12.4 kg) performed first a discontinuous incremental freestyle test (FS_EXT) and then two 7-min constant velocity freestyle swims (FS_CTA and FS_CTB), in a 50m pool, over a 10 day period. Cardiorespiratory analysis of expired air was performed in all three tests, which were each separated by at least 24h rest, using a breath by breath analyser (K4b2, Cosmed, Italy) and swimming snorkel (Aquatrainer, Cosmed, Italy).

The discontinuous incremental test (FS_EXT, Roels et al., 2005) comprised 5 x 200 m swims with 30 s rest intervals. Speed was increased by 5-10% for each stage, the last of which was performed at maximal speed (vVO2max). Maximal oxygen uptake (VO2max) was taken as the highest 30 s VO2 average; the ventilatory threshold (VT) was established by the V-slope method, and the OBLA was determined from fingertip blood lactate concentration ([La], obtained between each 200m stage using a Lactate Pro analyser), in FS_EXT).

The two 7-min constant velocity exercise bouts (FS_CTA and FS_CTB) were each performed at Δ70% [= VT + 0.70 x (VO2max - VT)].

Performance was taken as official 400m completion time (T400) within a freestyle swimming competition that took place within one month of FS_EXT, FS_CTA and FS_CTB.

The breath-by-breath data of FS_CTA and FS_CTB were 1-s interpolated, time-aligned and averaged. The parameters of the VO2 kinetics (td1, τ1, A1, td2, τ2, A2; i.e. time delay, time constant and amplitude of the primary phase and slow component, respectively) were modelled with two exponential functions.

Results: τ1 (15.8 ± 4.7 s) was significantly correlated with T400 (251.4 (Mean) ± 12.4 s (SD); r = 0.61; p = 0.02), absolute VO2max (4.2 ± 0.76 L.min-1; r = -0.66; p = 0.01) and vVO2max (1.46 ± 0.07 m s-1; r = -0.61; p = 0.02). None of the other measured VO2 kinetics parameters (td1: 12.2 ± 2.7 s; A1: 40.6 ±4.7 ml.kg-1.min-1; td2: 167 ± 67 s; τ2: 115 ± 172.4 s; A2: 3.6 ± 2.5 ml.kg-1.min-1).were significantly correlated with T400. T400 was significantly correlated with absolute VO2max (r = -0.70, p = 0.01); and speed at both OBLA (1.34 ± 0.01 m.s-1; r = -0.88; p = 0.00) and VT (1.26 ± 0.08 m.s-1; r = -0.80; p = 0.00).

Conclusion: The shorter time constant for the primary phase of the VO2 response in swimming (but not the amplitude of the slow component) appears to be associated with higher aerobic fitness and performance.

THE USE OF NUTRITIONAL SUPPLEMENTS BY ELITE PORTUGUESE SWIMMERS

TEIXEIRA, V.H., SOUSA, M., MOREIRA, P.

UNIVERSITY OF PORTO

Introduction: A well-planned diet provides the athlete with adequate levels of nutrients; however, there are many sportsmen/sportswomen taking nutritional supplements (NSs) in spite of their possible contamination with prohibited compounds and the unproved efficacy of the majority of them. In Portugal, no official data regarding the consumption of NSs is available. This study aimed to determine the prevalence and determinants of the use of NSs by elite Portuguese swimmers.

Methods: Thirty six swimmers (14 women; 17.3 years), belonging to the Portuguese national team, volunteered to participate in this study. Between January and March, subjects were asked to complete a questionnaire that included questions to characterise the use of NSs, and a semiquantitative food-frequency questionnaire.

Results: The prevalence of the use of NSs was 91.7%, with a mean consumption of 3.7 NSs per swimmer (between 1 and 10). Regarding the type of supplements and fluids ingested, the most used were sport drinks (75.8%), magnesium (60.6%), multivitamins/minerals (57.6%), proteins (27.3%) and vitamin C (21.2%), with no significant gender and age category (<18 years vs. ≥18 years) differences. The most frequent reasons for the intake of NSs were: 'to improve sports performance' (57.6%), 'to have more energy/to reduce fatigue' (57.6%), 'to accelerate recovery' (42.4%), "to have more focus" (15.2%, with an age-based difference: <18 years=23.6%; ≥18 years=64.3%; p=0.034) and "to prevent/to treat diseases or injuries" (15.2%). Physicians (57.6%), coaches (30.3%), family (24.2%) and the swimmer him/herself (21.1%) were the main source of information and advice, with no statistical differences between gender and age groups. The estimated intakes for most nutrients (16 studied) were above the recommendations. For girls between 19 and 30 years (n=4), the estimate mean ingestion of potassium (4305 mg/day), calcium (938 mg/day), folate (385 mcg/day), vitamin D (3.6 mcg/day) and vitamin E (10.8 mg/day) was under the recommendations. For boys with 14-18 years (n=11), the estimate mean intake of potassium (4392 mg/day), vitamin D (4.8 mcg/day) and vitamin E (13.2 mg/day) was under the recommendations. For males with ages between 19 and 30 years (n=11), only the estimated mean intake of vitamin E (12.9 mg/day) was under the recommendations.

Conclusions: The prevalence of the consumption of NSs was high and not justified due to an adequate nutrient intake by swimmers. In general, the type of NSs used and their determinants were not associated with gender or age group. Therefore, dietary education could be beneficial to maximize elite swimmers' performance and health benefits that result from optimal nutrition.

PHYSIOLOGICAL AND PSYCHOLOGICAL ASPECTS OF SWIMMERS IN DIFFERENT TRAINING PERIODS

SIMOLA, R., SAMULSKI, D.M., PRADO, L.S.

FEDERAL UNIVERSITY OF MINAS GERAIS, BRAZIL

Introduction: Even though many investigations have studied the psychological and physiological responses of athletes to periods of intensified training, only sparse information is provided regarding the interactions of these responses during the recovery period (Steinacker et al. 2000). Therefore, we aimed to investigate the effects of different training loads on stress and recovery perception (SRP) and on plasma activity of creatine kinase (CK).

Methods: Subjects were highly trained, male swimmers (17.7 + 1.3 y.o.). SRP and CK were evaluated after two distinct training phases. On the first, subjects swam approximately 50.000 meters in the week during 5 weeks. On the second, swimmers covered an average of 25.000 meters in the week, for 2 weeks. 05 ml blood were obtained from the antecubital vein for determination of CK. SRP was evaluated using the questionnaire RESTQ-Sport for the Portuguese language (Costa & Samulski, 2005). The Student's t-test and Pearson's product moment correlation were used for statistical analysis. Significance level was $p<0.05$.

Results: After the second training phase, a significant reduction of CK was observed when compared to the first measurement (261.66 + 120.04 U/L; 167.92 + 57.14 U/L), along to a reduction of scale scores in RESTQ-Sport Conflicts/Pressure (2.42 + 0.79; 1.98 + 0.9), Fatigue (2.28 + 1.07; 1.12 + 0.71), Lack of Energy (2.02 + 0.83; 1.5 + 0.61), Perturbations on Intervals (2.00 + 0.69; 1.23 + 0.75) e Lesions (2.5 + 0.91; 1,57 + 1,04). Furthermore, significant increases were seen on scales Physical Recovery (3.07 + 1.23; 3.75 + 1.08) and Being in Shape (3.23 + 1.23; 4.00 + 1.12). However, no significant correlations between scores and CK were observed in any of the sampling phases. Conclusion: Sharp training volume decreases after a period of high training loads may cause improvements on psychological and physiological profiles of the athletes investigated. However, these aspects may not necessarily be correlated.

AGE-RELATED CHANGE IN KNEE EXTENSORS AND FLEXORS RATE OF FORCE DEVELOPMENT AND ITS RELATION TO POSTURAL STABILITY

BEZERRA, P., ZHOU, S., CROWLEY, Z., BAGLIN, R.

SOUTHERN CROSS UNIVERSITY, NSW, AUSTRALIA

Introduction: The ability to develop force rapidly, assessed as the rate of force development (RFD), in the knee extensors declines significantly with increasing age with negative impact in controlling posture 1. Little research has examined the age-related change in knee flexors RFD and its association with postural control. The aim of this study was to examine whether knee extensors and flexors RFD changes differently across lifespan and the relationship between knee flexors RFD and postural control, in both men and women.

Methods: Traditional centre of pressure (COP) and stabilogram parameters were examined on hard and soft surfaces with eyes open and closed. The RFD of knee extensors and flexors was assessed in static knee extension and flexion. Three groups of healthy volunteers, aged 18-30 (YG), 40-50 (MG) and 60-77 (OG) years, with 10 males and 10 females in each were recruited from local populations. General linear model multivariate analysis with group and gender as fixed factors were performed to compare the between group RFD differences, and bivariate correlations were used to examine the relationship between RFD and COP. Testing procedures were approved by the Human Research Ethics Committee of the University and written informed consent was obtained from the subjects.

Results: Significant lower RFD was found in OG compared with YG and MG in knee extensors ($p < 0.001$ and $p < 0.05$) and flexors ($p < 0.01$ and $p < 0.001$) RFD. The ability to develop force rapidly was higher in males than females in all age-groups ($p < 0.001$). Both MG and YG were significantly better from OG in COP mean distance in anterior-posterior (AP) direction ($p < 0.05$) and COP mean velocity in AP and medial-lateral (ML) directions ($p < 0.001$). Moderate negative correlations were found between COP mean velocity in ML and knee extensors ($r = -0.30$ to -0.37, $p = 0.05$) and flexors ($r = -0.32$ to -0.40, $p = 0.05$ to 0.01) in all posture testing conditions.

Discussion/conclusion: Results showed significant age-related decreases in RFD of knee extensors and flexors. However, the ability to develop force is maintained until the fifth decade. The increased amount of postural sway in ML appears to be the best marker for risk of falling 2. Both knee extensors and flexors RFD showed significant negative correlations with COP mean velocity in ML. It appeared that the higher RFD the better the postural control performance. It is suggested that RFD be further examined for its validity as a good indicator in postural control, particularly in the knee flexors.

DO ADHD CHILDREN WITH HIGHER PHYSICAL ACTIVITY HAVE WEIGHT PROBLEMS?

LIN, C.Y., YANG, A.L., LIN, C.L., SU, C.T.

NATIONAL CHENG KUNG UNIVERSITY

Introduction: Children with Attention deficit hyperactivity disorder (ADHD) are characterized by higher level of physical activity (PA), which often disturbs the life of these children and their families. Many studies have addressed the negative influences caused by their too much PA. However, few articles explored the possible positive effects produced by the higher level of PA. Appropriate amount of PA was known as an important factor of healthy physical status, such as proper body weight. Since the children with ADHD tended to have higher level of PA, we would like to explore its influences on the body weight. We hypothesized that the percentage of obesity or overweight of the children with ADHD, who have higher level of PA, would be less than the typically developing children.

Methods: 17 boys with ADHD (ADHD group), diagnosed by DSM IV, and 17 typically developing boys (control group) participated in the study. The informed consent was obtained from each participant and their parents. The height, weight, body mass index (BMI), and age in the ADHD group were 134.66+-19.53 cm, 34.94+-15.10 kg, 18.31+-3.20, and 103.29+-33.45 months, respectively. The height, weight, BMI, and age in the control group were 132.96+-11.33 cm, 35.66+-12.20 kg, 19.59+-3.85, and 109.24+-23.22 months, respectively. BMI was calculated by square height (m2) divided by weight (kg), and the weight status was determined by BMI and age. In order to confirm that our ADHD group had higher level of PA, each child was asked to wear a uni-axial accelerometer (ActiGraph GT1M) during the waking time of one week to measure the objective PA in daily life.

Results: PA in ADHD group (1.62+-.11) was confirmed to be higher than the control group (1.46+-.10) as indicated by the metabolic equilibrium (MET) per minute during one week ($p < .01$).The prevalence of normal weight, overweight, and obesity in the ADHD group were 58.82%, 29.41%, and 11.76%, respectively. The prevalence of normal weight, overweight, and obesity in the control group were 64.71%, 17.65%, and 17.65%, respectively. No significantly statistic difference between the two groups in the weight status (chi square =.748, $p = .79$).

Discussion: The study indicated that the children with ADHD did not have benefit on the weight status by their higher level of PA. We found that the ADHD group has the similar percentage of overweight and obesity with the control group. Our study suggested that the issue of obesity should be also of concerns for children with ADHD, although they demonstrated higher level of PA than their control peers.

SUSTAINED BENEFITS OF YOUTH SPORT FOR METABOLIC SYNDROME IN ADULTHOOD

YANG, X., TELAMA, R., HIRVENSALO, M., VIIKARI, J.S.A., RAITAKARI, O.T.

LIKES-RESEARCH CENTER FOR SPORT AND HEALTH SCIENCES, JYVÄSKYLÄ

Introduction

The effect of sustained youth sport on metabolic syndrome (MetS) in adulthood is not well investigated using longitudinal design. This study aims to examine the association between sustained youth sport and adult MetS over a period of 21 years in a population-based cohort of young adults.

Methods: Data were obtained from the Cardiovascular Risk in Young Finns Study in which 1493 young subjects participated in the study in 1980, 1983 and 2001. The participants were 9-, 12-, 15-, and 18-year-olds in 1980, and 30-, 33-, 36- and 39-year-olds in 2001. Participation in organized youth sport was assessed using a self-report questionnaire completed in connection with a medical examination in 1980 and 1983. By summing two items (participation in sport-club training and competitions) an index was formed for both measurement points according to which the participants were classified into four groups: Persistently athletic, Starters, Leavers and Non-athletic. MetS risk in 2001 consisted of fasting insulin, waist circumference, serum triglycerides, inverted HDL cholesterol, systolic blood pressure, diastolic blood pressure, and plasma glucose, which was defined as a categorical variable according to the guidelines of the European Group for the Study of Insulin Resistance (EGIR) and as a continuous MetS-score variable by summing the z-scores of single metabolic variable.

Results: In both males and females, sustained intensive sport participation in youth during 3 yr was inversely and significantly associated with clustered MetS-score and prevalence of MetS defined by the EGIR in adulthood ($p < 0.05$). Persistently athletic and Starters during 3 yr were less likely to have MetS than Non-athletic in both genders. Subjects who dropped out from organized sport were more likely to have MetS-score compared to persistently athletic subjects. Similar associations were found using EGIR MetS as an outcome. These associations remained significant after adjustment for age and baseline clustered MetS-score and after additional adjustments for adult leisure-time physical activity.

Discussion: We conclude that participation in, particularly sustained participation in organized sport in youth is associated with reduced the risk of developing MetS in adulthood. Organizers of youth sport may have a great impact on public health by paying attention to the factors which increase adherence in youth sport.

THE EFFECT OF EXERCISE ON FALL-RELATED PHYSICAL FITNESS AND VARIOUS CHARACTERISTICS OF CHRONIC PAIN IN OLDER ELDERLY

KANG, H.

SOONCHUNHYANG UNIVERSITY

Introduction: Falls are a leading cause of mortality and morbidity among elderly age 75 and older. Preventing and delaying the onset of physical frailty is an increasingly important goal because more individuals are living well until their 8th and 9th decades. Exercise is recommended to elders in aspect of improving physical fitness significantly. The purpose of this study was to investigate fall-related physical fitness and the various characteristics of chronic pain in the older elderly who have the degenerative arthritis symptoms.

Methods: Twenty two elderly people, age 80(±3.8) were randomly selected. Fall-related physical fitness consisted of the 7 performance test items, which were muscle strength (grip strength), muscle endurance (standing up and sitting on a chair), flexibility (chair sit and reach), agility (timed up and go), cardiovascular endurance (2min walking), balance (one leg balance with eye opened) by Rikli and Johns (2001)'s Senior Fitness Test Manual. Pain score was measured by static and dynamic visual analog scale (VAS sore: 0=no pain, 10= extremely unsatisfactory). The falls prevention program performed for about one hour per day, 4 times a week over a period of 10 weeks in 60-80% HRR.

Results: The result showed that significantly improved on flexibility (-.05±7.9cm vs 3.7±7.6cm, $p<0.05$), agility (12.1±3.6sec vs 10.3±4.1sec, $p<0.05$), balance (right: 10.0±8.3sec vs 23.6±23.6sec, $p<0.05$). Chronic pain scale at 10 week showed significant decreased on pain symptom (4.73±2.0 vs 3.5±2.0, $p<0.001$), pain symptoms when walking (4.9±3.0 vs 3.7±2.8, $p<0.05$), pain symptom when sitting (5.0±3.4 vs 3.7±2.8, $p<0.01$), pain symptom in daily living (4.4±2.7 vs 3.3±2.3, $p<0.01$).

Discussion: In conclusion, there has been a substantial improvement in 10 weeks by falls prevention program, but exercise program should be recommended to elders in aspect of increasing cardiovascular endurance and muscle strength. We also suggest that the unresolved issues include development of optimal strategies for motivating and applying in older elderly to begin and maintain exercise program.

USING CHALLENGING, NATURAL ENVIRONMENTS TO ENHANCE BALANCE PERFORMANCE IN THE ELDERLY

ADLER, H., NAGEL, V., LIPPENS, V.

HIS E.V.

Introduction: Maintaining individual mobility and independence in later life belongs to the prior concerns of aging individuals and whole populations. An age-related decline of the ability to modulate posture according to environmental and task-specific demands has been observed, falls often are the consequence. Impacts and outcomes of public health approaches cannot be described as successful yet, mainly not reaching the main target groups and hence leaving room for improvement. Contents of effective fall prevention programs have been identified (e.g. Oddsson et al. 2007), but often unvarying, standardized exercises are being offered to improve strength or balance, regardless of everyday functional demands. A complex environment is known to enhance physical activity and neurogenesis (cf. Schaefer et al. 2006), diverse natural surroundings should therefore be considered as potential settings to interventions.

Methods: During a 10-day course a constraints-led approach (cf. Araújo et al., 2004) was used in a group of elderly participants (n=11, mean age 58.36; SD 5.39) in a challenging, natural environment with the aim to enhance smart balance performance in everyday situations. To enable transfer of acquired balance strategies to individual everyday-surroundings, transfer-supporting methods were used

(Nagel 1997). As one parameter for postural adaptation, balance performance was measured monopedal on a balance disc with a suprapostural task before, after, and three months after the course.

Results: In contrast to the control group (n=22), the intervention group showed an improvement in balance performance by 25% after the course, remaining stable over three months. A group-effect (F(1,56)= 6.901, p=.01) could be revealed by an ANOVA.

Discussion: Movement patterns emerge according to personal, environmental and task constraints (Newell, 1986). The modulation of task and environmental constraints is an underestimated method to provoke appropriate movement task solutions and enhance motor competence in the elderly. Natural surroundings can be a motivating and economic setting to meaningful movement not only for purposes of public health.

POST-EXERCISE PRESSURE RESPONSES IN ELDERLY PRE-HIPERTENSE WOMEN ARE INFLUENCED BY NITRIC OXIDE

SANTANA, H.A.P., MOREIRA, S.R., DA SILVA, C.B., BOTELHO NETO, W., BENFORD, R.E., CAMPBELL, C.S.G., SIMÕES, H.G.

CATHOLIC UNIVERSITY OF BRASÍLIA

Introduction: Exercise has been proposed to treatment and/or control of hypertension. Thus, the aim of this study is to verify blood pressure responses after different intensities of aerobic exercise in elderly pre-hypertensive women, verifying metabolites liberation related to it.

Methods: Thirty elderly women (70.5±6.0yrs, 60.4±8.5kg) realized: 1stday - 20min in rest (R) measuring blood pressure (BP) and began an incremental test (IT) in bicycle that was used as well to measure the anaerobic threshold (AT). Then, they remained sated for 1h for recovery measuring the BP every 15min; 2ndday: they did the same pre/post test procedures and measurements, and exercise for 20min in 90% AT; 3rdday: they did the same procedures, and remained sated (control-CONT) for 20min. Saliva was collected in the same moments of measuring BP and right after exercise (RAE) for measurement of nitrite (NO2-, product of oxidation of Nitric Oxide). All sessions were realized in random order.

Results: The SBP values were IT (R=127.5±15.9mmHg vs. 1hMean=122.0±14.2mmHg; p<0.01), 90%AT (R=121.4±12.4mmHg vs. 1hMean=119.3±13.2mmHg; p>0.05) and CONT (R=120.8±14.9mmHg vs. 1hMean=124.0±14.0mmHg; p<0.01). For DBP occurred in IT (R=76.8±7.9mmHg vs. 1hMean=77.5±8.2mmHg; p>0.05), 90%AT (R=74.2±6.4mmHg vs. 1hMean=75.3±5.9mmHg; p>0.05) and CONT (R=73.6±7.4mmHg vs. 1hMean=76.4±7.3mmHg; p<0.01). And the MAP results were IT (R=93.7±9.7mmHg vs. 1hMean=92.3±9.5mmHg; p>0.05), 90%AT (R=89.9±8.0mmHg vs. 1hMean=90.0±7.8mmHg; p>0.05) and CONT (R=89.3±9.1mmHg vs. 1hMean= 92.3±9.0mmHg; p<0.01). ANOVA showed difference in the variation among sessions of SBP (CONT∆=3.2±6.6mmHg vs. IT∆=-5.6±7.6mmHg; p<0.01 and 90%AT∆=-2.1±7.5mmHg; p<0.05) and MAP (CONT∆=3.0±3.5mmHg vs. IT∆=-1.4±5.6mmHg; p<0.01 and 90%AT∆=0.1±4.9mmHg; p<0.05). NO2- values were in IT (R=278.9±166.1μM vs. RAE=359.0±228.2μM; p<0.01), 90%AT (R=267.9±175.0μM vs. RAE=338.8±283.7μM; p=0.07) and CONT (R=279.7±163.3μM vs. RAE=292.9±234.5μM; p>0.05). Differences also occurred in NO2- (CONT∆=13.3±185.1μM vs. IT∆=80.2±146.9μM (p<0.01) and 90%AT∆=70.9±199.1μM (p<0.01).

Discussion: Only on IT occurred PEH on the SBP, otherwise both IT and 90% AT offers protective effect on the SBP and MAP when compared with CONT group. This study, bringing a different population – elderly, agrees to other studies showing the benefits of exercise in moderate intensities for control of BP (MacDonald et al., 2001). Although elderly people have an impaired capacity of the vasculature to increase nitrite (Lauer et al., 2008), what might had prejudice a PEH in 90% AT in our study. However, a difference between the groups occurred, showing the importance of the exercise in higher intensities (IT) to promote PEH and the protective effect of aerobic exercise not leading the BP increase like in CONT.

ADULTS WITH ADHD RATE EXERTION LOWER

MAMEN, A., SKREDE, A., MUNKVOLL, H., MARTINSEN, E.W.

SOGN OG FJORDANE UNIVERSITY COLLEGE

Introduction.

There are many anecdotal stories about how restless and inexhaustible persons with attention deficit/hyperactivity disorder (ADHD) are. The name of the diagnosis itself also indicates this with the word hyperactivity. We wanted to know whether adult patients with ADHD differed in fitness and reaction to exercise compared to patients without this disorder. To investigate this we used the participants in

clinical exercise intervention project for patients with substance abusers or dependence, since these patient groups have a high prevalence of ADHD.

Methods: Thirty adults with substance dependence, of which 13 had DSM-IV ADHD, were tested on the treadmill for lactate threshold and maximal oxygen uptake (VO2max). The threshold testing protocol consisted of several five min long exercise bouts separated with 30 s resting periods for blood collection with a LP1710 lactate analyser (Arkray Inc, Japan). The lactate threshold was defined as the speed giving a blood lactate concentration (BLC) 1.5 mmol•L-1 above resting BLC value. The Bruce protocol was used for establishing VO2max with a MetaMax CBS (Cortec Biophysik, Germany) metabolic cart analysing the expired air. Rating of perceived exertion (RPE) according to the15-point Borg scale was recorded at the end of each exercise bout and RPE at threshold point (RPELT) was calculated using linear regression.

Results: Subjects with ADHD rated the RPELT significantly lower than the non-ADHD group, 10.9 vs. 13.0 (p=0.009). This despite having a higher Threshold heart rate (HRLT), 151 vs. 141 beats•min-1 (p=0.022) and blood lactate concentration (BLC) at threshold, 2.8 vs. 2.4 mmol•L-1 (p= 0.009). The maximal oxygen uptake was 46 vs. 44 ml•kg-1•min-1 (p=0.409) for the ADHD and non-ADHD groups respectively, and thus adequate for performing heavy physical work.

Discussion: The self-presentation theory of Goffman may be useful to understand the differences seen in RPE scores: The goal of the self-presentation is to achieve acceptance from the "audience". This can be done through manipulation and playing a role. If the "actor" succeeds, the audience will view the actor as he or she wants to be viewed. Another aspect of self-presentation is "self-constructive self-presentation", aiming at making people believe that they are what they would like to be. The ADHD person might feel more inclined to "show him/herself" in a positive way in a social setting, and thereby reducing the experienced effort from the test to appear more fit. Further research is needed to verify the findings of this study and try to elaborate the mechanisms of reduced RPE scores here seen in adults with ADHD and substance dependence.

AGEING, WELL BEING AND BODY IMAGE IN FRENCH ELDERLY PEOPLE PRACTISING PHYSICAL ACTIVITY REGULARLY: A SELF-DETERMINATION THEORY PERSPECTIVE AND A QUALITATIVE STUDY

FERRAND, C., NASARRE, S., HAUTIER, C., BONNEFOY, M.

UFR STAPS CRIS, UNIVERSITÉ LYON 1 AND CENTRE HOSPITALIER LYON SUD, UNIVERSITÉLYON 1

Including regularly physical activity in our daily lives leads to a multitude of physical, psychological, and social benefits (Warburton, Nicol, & Bredin, 2006), particularly for elderly people. The aim of this study was to achieve a better understanding of the motives used by elderly people for maintaining an active lifestyle, and to rely on self-determination theory as a useful framework (Deci & Ryan, 1985). It looks at highly self-determined elderly people practising voluntarily physical activities in an association managed by them in order to explicate the motivational mechanisms impacting the management of their successful ageing.

Method: The target population consists of 19 elderly people belonging to an association called « CODAPRS » which organizes physical activities for retired people above fifty years in urban area. Participants were selected randomly from whose who had indicated a willingness to participate and who had had high scores on the self-determination index (SDI), reflecting a more self-determined motivational orientation (Brière, Vallerand, Blais & Pelletier, 1995). Thus, nine women and ten men (Mage = 74.59, SD = 4.64) practising around 8 hours of physical activity per week signed the consent form and accepted to be interviewed. All interviews were audiotaped, transcribed verbatim and returned to the participants. Sources of triangulation were literature reviews related to ageing and physical activity, health professionals and the use of peer researchers as an external audit.

Results and Discussion: Inductive content analysis was used to analyse the interview transcripts, and yielded three themes (namely well being, relational and body image benefits) with six subthemes including in each theme: a) Escape daily concerns and experience good emotions, relate to physical and mental capacities, keep a physical autonomy for a long time, keep in contact with nature, intrinsic pleasure to physical activity, better quality of sleep; b) Increase contact with other participants, avoid loneliness, share conviviality time, take part in activity with spouse, seek emulation though the group, get involved in voluntary work; and c) Keep in shape, better understand and push back the physical limits,self-fulfilment, proving one's continuing ability, increase effort and seek a dynamic image with a lot of vitality and energy. This study showed the psychological importance for these elderly people to remain active, and practising physical activities was a mean to preserve a social aspect and resist the powerlessness of ageing. Thus, these behaviours contribute to give a new image of retired people.

MENTAL FATIGUE AS A TOOL IN SPORTS AND EXERCISE: EVALUATION OF PERFORMANCE, PERCEPTION AND BRAIN ACTIVITY

BAUMEISTER, J., REINECKE, K., ST CLAIR GIBSON, A., RAUCH, L., NOAKES, T., WEISS, M.

INSTITUTE OF SPORTS MEDICINE, UNIVERSITY OF PADERBORN, GERMANY

Purpose: Mental fatigue seems to be an underestimated and not well evaluated part of sports and exercises. When people become mentally fatigued, they usually experience difficulties in maintaining the task performance at an adequate level. Interventions which induce mental fatigue may help us to understand the complexity of fatigue and its influence in sports and exercise.

Mental fatigue leads to temporary deterioration of attentional functioning, response readiness and increases in the number of behavioral errors. The working memory (WM) plays a prominent role in this context and can be measured by EEG (frontal Theta related to attention and parietal Alpha-2 spectral power related to information processing). The aim of this pilot study is to see if prolonged cognitive performances with high demands lead to mental fatigue demonstrated by changes in task performance, fatigue perception and EEG power values.

Methods: Eight male, right-handed volunteers (26.4±4.1 years; 86.7±4.8 kg; 189.4±2.1 cm) were required to repeat five Rapid Visual Information Processing (RVIP) tasks (5x5 min). The RVIP task provides performance scores (reaction times, correct/incorrect/missed responses). After each block the participants were asked to rate their mental fatigue using visual analogue scales. Before (rest) and during the tasks the EEG was measured in accordance with standards of the international 10:20 system from 13 scalp locations (Fz, F3, F4, Cz, C3, C4, Pz, P3, P4, T3, T4, T5, T6) and divided into different frequencies: Theta (4.75–6.75 Hz), Alpha-1 (7–9.5 Hz), Alpha-2 (9.75-12.5 Hz) and Beta-1 (12.75–18.5 Hz). EEG power values were calculated and log-transformed.

Results: Statistical analysis showed significant slowing of reaction times over time (F4,28=3.985; p≤.011; part.η2=.361). This was associated with an increase in fatigue perception (F4,28=9,231; p≤.001; part.η2=.568). Right hemispheric temporal Alpha-2 frequency (T3) demonstrated a fatigue effect with an increase in spectral power (F4,28=3.058; p≤.033; part.η2=.304).

Frontal Theta and parietal Alpha-2 power values demonstrated an activation compared to rest (p≤.01), but showed no significant effect according to mental fatigue.

Conclusion: In accordance with our aims, the participants did appear to be mentally fatigued as described by a decrease in performance and an increase in fatigue perception. This was in accordance with significant increased temporal Alpha-2 power which is discussed in terms of a decrease in mental activity specifically a reduction of symbolic/verbal activity. The EEG frontal Theta and parietal Alpha-2 power demonstrated an activation pattern (WM), but show no changes in relation to the fatiguing task. The authors speculate that a longer task performance over time would lead to changes in this EEG power values. Therefore to induce mental fatigue as a tool it may be necessary to demonstrate mental fatigue not only in performance and perception but additionally at the brain level.

GOAL ORIENTATION AND PERSISTENCE IN YOUTH ICE HOCKEY

KONTTINEN, N.

KIHU RESEARCH INSTITUTE FOR OLYMPIC SPORTS

Introduction: Achievement Goal Theory (Nicholls, 1984) states that there are two dispositional perspectives, which determine how subjective success is evaluated. Task orientation refers to self-referenced perception of ability, whereas ego orientation means that a person's focal concern is mainly towards demonstrating superior competence based upon normative comparisons. It has been suggested that a task orientation more often than the ego orientation protects the athlete from disappointments and a lack of motivation (Duda, 1989). Emphasis on task orientation can be expected to lead to a stronger persistence when an athlete's performance is exceeded by others. The purpose of the present study was to gain additional insights into this issue focusing on the relationship between goal orientation and involvement in organized youth sports.

Methods : The participants were 2,813 Finnish junior level ice hockey players. A longitudinal follow-up design was applied. A valid racing license of the Finnish Ice Hockey Association was used as the indicator of persistence 3,5 years after the initial survey questionnaire, when the participants ranged in age between 14 and 15 years (Mean; S.D: age 14.90; 0.29 years). Goal orientation was examined with the Finnish version of the Perception of Success Questionnaire or POSQ (Liukkonen, 1998; Roberts, Treasure, & Balague, 1998) . The dependence of persistence on goal orientation (task and ego) and perceived ability in ice hockey (low, intermediate, high) was studied with forward stepwise logistic regression with LR test in removing variables.

Results: It appeared that the players who scored high on task orientation were more likely to continue their participation in ice hockey than the players who scored low on task orientation. High ego orientation combined with high perceived ability was also associated with sustained involvement in ice hockey, whereas high ego orientation combined with low perceived ability appeared to be detrimental to the continuation of involvement.

Discussion: The results lend support for the view that goal orientation is related to sustained sport participation over the time span of several years. As expected, emphasis on task orientation appeared to lead to a stronger persistence. Interestingly, the results also showed that the likelihood of withdrawal from ice hockey increased, if a player whose goal was to win others (high ego orientation) experienced little success (low perceived competence). The results suggest that the investigation of goal orientation provides valuable additional information concerning a youth player's persistence for training in the face of failures and disappointments.

DIFFERENCES BETWEEN YOUTH ATHLETES AND THEIR PARENTS PERCEPTIONS OF SELF AND OTHERS' AGGRESSIVE BEHAVIOUR IN ICE HOCKEY

DORSCH, K., RIEMER, H.A., KARREMAN, E.

UNIVERSITY OF REGINA

Introduction: For lay people, aggression is often seen as a coveted characteristic of the successful athlete. Sport psychologists define it as an overt behaviour in which the athlete intends to harm another person either physically or psychologically (Silva, 1980). Many intra- and inter-personal factors affect perceptions of whether an act is or is not aggressive. For example, in what context did the aggressive behaviour occur, how psychologically close is the observer to the actor or the victim of the action, and/or was the victim injured? To date, most studies examining perceptions of aggressive behaviours have (a) tended to examine the physical aspects of aggressive behaviours excluding the psychological component, (b) relied heavily on adult observers, and (c) not included familial units. The purpose of this study is to focus on these three limitations.

Methods: Responses from a sample of 510 Atom-aged (ages 9 and 10, majority were male) and parents/guardians (N = 834; 415 fathers, 419 mothers) were examined. The athletes were randomly selected from the registration lists of two provincial ice hockey associations in Canada. Cohorts were recruited to the project via telephone over the course of 3 years. Athletes and their parents were invited to complete a survey either on-line on a secure website or, by receiving a paper copy in the mail. The data were analysed using the family as the unit of analysis (N = 321 families with 3 members). Using a scale of 1 (Never) to 9 (Always), each participant was asked to indicate how often they perceived acts or encouragements of physical and psychological aggression to be committed by themselves, their parent/child, their coach, teammates, teammates' parents, opponents, opponents' parents, and opponents' coaches.

Results: Overall, mean scores for the 16 questions ranged from: athletes 1.12 (SD = .61) to 4.37 (SD = 2.26); fathers 1.11 (SD = .57) to 4.16 (SD = 2.14); and mothers 1.05 (SD = .27) to 4.69 (SD = 2.22). Even though the data was positively skewed, most questions spanned the entire range of responses. Friedman tests were conducted to analyse differences among the three family members. Significant differences ($p < .05$) were found for 11 of the 16 questions with the majority (8) finding the child to be significantly different from the parents.

Discussion: In general athletes and their parents report that aggressive behaviours do not occur very often. All three groups do not admit to encouraging or being encouraged to physically harm (lowest mean value of all scenarios). All groups agreed that most aggressive behaviours were committed by opponents with mothers perceiving this behaviour to occur more often than fathers and athletes.

REACTION TIME TO PERIPHERAL VISUAL STIMULI DURING EXERCISE UNDER HYPOXIA

ANDO, S., YAMADA, Y., KOKUBU, M.

KYOTO PREFECTURAL UNIVERSITY OF MEDICINE

Introduction: Reaction time (RT) to peripheral visual stimuli increases during exercise at high workloads (Ando et al., 2008). However, physiological mechanisms underlying the detrimental effects of exercise on RT to peripheral visual stimuli remain to be elucidated. The purpose of this study was to test if hypoxia affected reaction time (RT) to peripheral visual stimuli during exercise. We expected that if decrease in oxygen availability is responsible for the increase in RT to peripheral visual stimuli during exercise, RT to peripheral visual stimuli would, to a greater extent, increase during exercise under hypoxia as compared with exercise under normoxia.

Methods: Ten male participants performed RT tasks at rest, during and after cycling with three different workloads [40 %, 60 %, and 80 % peak oxygen uptake (VO_2)] under either blinded normoxic [inspired fraction of oxygen (FIO_2) = 0.21)] or hypoxic (FIO_2 = 0.16) conditions. Visual stimuli were randomly presented at 10° to either the right or left of the midpoint of the participant's eyes. Cerebral oxygenation was continuously monitored over the right frontal cortex using near-infrared spectroscopy. In this study, RT was fractionated into premotor and motor components (Premotor time and Motor time) base on the onset of electromyogram recorded over the right forearm. We used Premotor time to assess the efficiency of central information processing.

Results: Under normoxia, Premotor time was significantly longer during exercise at 80% peak VO_2 (mean ± SE; 214.2 ± 10.4 ms) relative to that at rest (201.0 ± 8.6 ms) ($p < 0.05$). Under hypoxia, Premotor time was significantly longer during exercise at all workloads (40%: 216.3 ± 8.8 ms, $p < 0.05$; 60%: 216.1 ± 9.1 ms, $p < 0.05$; 80%: 221.5 ± 9.5 ms, $p < 0.01$) relative to that at rest (202.9 ± 9.4 ms). Increase in Premotor time during exercise was negatively correlated with corresponding cerebral oxygenation ($r2 = 0.85$, $p < 0.01$) when data from normoxia and hypoxia were combined together.

Discussion: The results of the present study indicate that the increase in Premotor time to peripheral visual stimuli during exercise is closely associated with decrease in cerebral oxygenation. It is possible that decrease in oxygen availability and/or alteration of neurotransmitters turnover contributed to the detrimental effects of exercise under hypoxia. We conclude that cerebral oxygenation influences visual perceptual performance during exercise.

'YOU NEED TO GET OUT MORE!': SOCIAL AND PHYSICAL ENVIRONMENTS OF SEDENTARY AND ACTIVE BEHAVIOURS OF YOUTH IN TWO CENTRAL-EASTERN EUROPEAN COUNTRIES

SOOS, I., BIDDLE, S., HAMAR, P., SANDOR, I., SIMONEK, J.

1. UNIVERSITY OF SUNDERLAND, 2. LOUGHBOROUGH UNIVERSITY, 3, SEMMELWEIS UNIVERSITY, BUDAPEST, 4. BABES-BOLYAI UNIVERSITY, CLUJ-NAPOCA, 5. CONSTANTINE THE PHILOSOPHER UNIVERSITY, NITRA

Introduction: There has been an increase in the study of sedentary behaviours in young people. Evidence shows that time spent in some sedentary behaviours may be associated with negative markers of health. However, in addition to studying the prevalence of sedentary behaviours, it is important to ascertain where such behaviours are taking place and whether different sedentary behaviours are intercorrelated. The main aim of this study, therefore, was to investigate the social and physical context of sedentary behaviours, as well as the interrelationships between behaviours.

Methods: Secondary school students (n=440), aged 13-18 years, from two countries (Romania n=313 and Slovakia n=127) were assessed. Ecological momentary assessment was used in the form of a free-time diary and was administered across three weekdays in 2006-2007.The temporal factors and correlates of the key sedentary behaviours, the locations and the social context were analysed using SPSS 15.0 software package.

Results and Discussion: Temporal and location Results: TV viewing (97.45 min, s=65.14) occupied the most time of any single behaviour, followed by doing homework (91.51 min, s=60.91), active transport (40.68 min, s= 29.14), and sitting and taking (27.61 min, s=32.59). Playing computer/ video games had a low mean score (15.0 min, s=34.84). Students spent most of their time in the bedroom (309.70 min, s=109.49) and living room (75.15 min, s=84.69), and much of their time alone (322.89 min, s=124.76), but also with friends (140.41 min, s=100.02), or with family (140.0 min, s=101.75).

Correlates of behaviours

TV viewing negatively correlated with reading (r=-0.29*), active transport (r=-0.28*) and doing homework (r=-0.23*). Active transport also negatively correlated with using a computer (r=-0.22*). Playing computer/ video games positively correlated with cognitive hobbies (e.g.,

doing puzzles, playing cards) (r=0.20*) (* p<0.001). Being outside was associated with more active behaviours (rs=0.21-0.44*) while being inside was associated with more sedentary behaviours.
Conclusion. Young people need to be encouraged to spend more time outside to reduce sedentary behaviours and increase physical activity.

THE EFFECTS OF A 2 YEAR SCHOOL-BASED PHYSICAL ACTIVITY AND DIETARY INTERVENTION PROGRAM ON PHYSICAL FITNESS AND BODY COMPOSITION

JOHANNSSON, E., HRAFNKELSSON, H., MAGNUSSON, K.

CENTER FOR RESEARCH IN SPORT AND HEALTH SCIENCES, UNIVERSITY OF ICELAND, REYKJAVÍK, ICELAND. SELTJARNARNES HEALTH CENTER, REYKJAVÍK, ICELAND.

INTRODUCTION: Overweight and obesity due to physical inactivity and unhealthy diet has become a widespread problem among children worldwide. The school setting has been suggested as an ideal platform to implement interventions that may tackle this problem. This study compared BMI, body fat % and physical fitness (PF) level between two study groups of children born in 1999 (7 years old at baseline) before and after a two-year intervention period.
METHODS: Six elementary schools in Reykjavik Iceland were randomly assigned into either an intervention group or to serve as controls. In 2006 children entering second grade at each participating school were invited to take part in the study. Participation of 268 children in some or all parts of the study produced 86% participation rate. At baseline and after a two-year intervention period the children's height and weight was measured. Whole body DEXA scans were run providing data on body composition, including body fat % and PF was assessed with a cycle ergometer, measured as watts/kg. Reliable data was observed from 170 children who participated in the three measurements at both time points. The main objective of the physical activity intervention was to better integrate physical activity and the schools' curriculum. Further, to increase physical activity up to at least 1 hr/day each school day. Hence, between fall of 2006 and fall of 2008 the physical activity level at the intervention schools was progressively increased via teacher-led daily activities. A two-way repeated measure ANOVA was performed to assess a change in outcome measures with time in both groups. Data was analyzed using R version 2.6.2.
RESULTS: The mean BMI and body fat % were slightly, yet significantly lower among children in the intervention group at both time points, but there was no significant interaction between group and time for either variable. However, there was not a significant difference in PF between the groups at baseline. A group by time interaction was demonstrated when comparing pre and post intervention PF (p=0.048). Children in the intervention group increased their PF capacity by 10% (2.49±0.58 watts/kg in 2006 to 2.74±0.53 watts/kg in 2008), while children in the control group increased their PF by 5% (2.36±.49 watts/kg in 2006 to 2.48±0.47 watts/kg in 2008). Similar yet not significant trends were observed when stratified by sex.
DISCUSSION: Our study suggests that the two-year school-based intervention program may have had positive effects on children's PF while no apparent effect was on children's BMI or body fat %. These results may add weight to the body of knowledge on how the school setting can effectively keep its children more active and healthier. Further analysis of the data may provide more specific reasons for this effect on children's fitness.

ASSOCIATION BETWEEN BODY FAT, SCREEN TIME AND PHYSICAL ACTIVITY IN 8-10 YEAR OLD CHILDREN EXCEEDING ELECTRONIC MEDIA GUIDELINES

GRAVES, L.E.F., RIDGERS, N.D., STRATTON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

OBJECTIVE: Previous associations between body fat, and, physical activity (PA) and screen time (ST), both predisposing factors for obesity (Myers, 2005), are limited by the use of body mass index as an indicator of adiposity, and pedometry or self-report as measures of PA (Kautiainen et al., 2005; Laurson et al., 2008). Using more sensitive methods this study examined associations of television viewing (TV), video gaming (VG), ST and PA on the percent total body fat (%BF) of children exceeding the daily recommended 2 hours of engagement with electronic media (American Academy of Pediatrics, 2001).
METHODS: A total of 47 primary school children (age mean 9.2, SD 0.6) provided at least 9 hours of accelerometry-derived habitual PA information on a minimum of 3 weekdays and 1 weekend day. Data were analysed using individually calibrated activity count thresholds for PA at 4km∙h-1 (PA4) and 8km∙h-1 (PA8), and a sedentary threshold of 100 counts per minute. Dual-energy x-ray absorptiometry (DEXA) was used to measure %BF. Weekday and weekend day TV and VG time were self-reported using a questionnaire, allowing calculation of a weekly estimate of each and ST (VG + TV). Correlations evaluated the strength of relationships between variables. Only significantly correlated variables were used in multiple linear regression and partial correlation analysis. This analysis helped explain the variance in %BF whilst controlling for age. Statistical significance was set at p<0.05.
RESULTS: Based on body fat reference curves (McCarthy et al., 2006), 19.5% of the group were overfat (≥85th <95th centile) and 40.4% obese (≥95th centile). VG, TV and ST were not significantly correlated with %BF (r < 0.2) or any PA variable (r > -0.23), except TV (r = -0.41) and ST (r = -0.26) with PA8. %BF was significantly correlated with sedentary time (r = 0.264), PA4, PA8, PA>4 and total PA (r < -0.3). Regression analysis showed only PA>4 and total PA significantly predicted %BF. Subsequent partial correlations indicated PA>4 and total PA explained 7.8% and 6.9% of the variance in %BF, respectively. A 1-minute increase in activity of intensity greater than 4km∙h-1, and total PA, is associated with a 0.062 (95% CI: -0.118 to -0.005) and 0.044 (95% CI: -0.087 to -0.001) decrease in %BF, respectively.
DISCUSSION: Stronger associations with %BF for PA variables compared to screen time variables suggest PA is a more important risk factor for overfat in children who exceed electronic media guidelines. Increasing total PA, and PA of intensity greater than 4km∙h-1, which is equivalent to walking, should be targeted in interventions seeking to reduce %BF in children who report high media usage.

IMPROVEMENT IN CHILDREN'S CARDIO-RESPIRATORY FITNESS FOLLOWING A TWO-YEAR SCHOOL-BASED DAILY PHYSICAL ACTIVITY INTERVENTION

RESALAND, G.K., ANDERSSEN, S.A., MAMEN, A., ANDERSEN, L.B.

SOGN AND FJORDANE UNIVERSITY COLLEGE

INTRODUCTION: Cardio-respiratory fitness is strongly associated with good health in children as well as in adults. There are conflicting results concerning the effect of increased physical activity (PA) on cardio-respiratory fitness in children. This may be due to the duration of studies or the volume of PA performed, among other things. The school provides an excellent setting in which to enhance levels of PA, and thereby possibly increase fitness. Few interventions in school assess VO2peak directly, which is a methodological weakness. We therefore started a 60-minute two-year school-based PA intervention for nine-year-olds in two Norwegian towns assessing fitness directly. To our knowledge the present study breaks new ground by being the first teacher-controlled daily PA intervention of this magnitude with direct measurement of VO2peak. The aim of the present study was to describe changes in children's cardio-respiratory fitness following a daily physical activity intervention in two Norwegian rural towns. METHODS: In total, 259 children (age 9.3±0.3 years) were invited to participate, of whom 256 participated. The intervention group (63 boys, 62 girls) carried out 60-minute teacher-controlled daily physical activity over two school years. The control group (62 boys, 69 girls) had the standard amount of physical education (45 minutes twice each week) in school. 188 (73.4%) children successfully completed both pre- and post-peak oxygen uptake test (VO2peak). VO2peak was directly measured during a continuous progressive treadmill protocol where the children ran until exhaustion. Body mass and height were collected from all 256 children at baseline. There was no difference in BMI between those included (188) or those excluded (68). Change in VO2peak was analysed with a General Linear Model with sex and location as fixed factors, and baseline VO2peak as a covariate. RESULTS: Mean baseline values were 52.8±6.5 ml kg−1 min−1 (boys) and 46.9±7.2 ml kg−1 min−1 (girls). The intervention group significantly increased their VO2peak (4.3±4.0 ml kg−1 min−1), while the control group did not (0.4±3.5 ml kg−1 min−1) ($p<0.001$). DISCUSSION: The main finding is that a two-year school-based 60-minute daily physical activity intervention significantly improved cardio-respiratory fitness in children. The present study suggests that increased PA levels and increased fitness in children should be taken into consideration when designing school policies. Establishing a lifestyle of regular exercise, and thereby contributing to a higher level of fitness in children, is important in many ways, including short- and long-term health benefits.

STRENGTH TRAINING AND THE MENSTRUAL CYCLE: EFFECTS OF FOLLICULAR- AND LUTEAL PHASE-BASED TRAINING ON MUSCULAR STRENGTH AND MUSCLE DIAMETER IN SUBJECTS WITH ORAL CONTRACEPTION

HAN, A., SUNG, E., HINRICHS, T., PLATEN, P.

RUHR-UNIVERSITY BOCHUM

Purpose: Modern monophasic oral contraceptives (OC) contain fixed doses of estrogen (E) and progestogen (P) which are taken for 21 consecutive days, followed by 7 days without any hormone intake. There wouldn't be any differences in blood concentrations of estradiol (E2) and progesterone (Prg) during the first 21 days of the menstrual cycle. The regulation of other interacting hormones like hGH, IGF-1, testosterone, and DHEAs, all of them possible anabolic hormones on the level of the muscular cell and important regulating factors during strength training, is not clear so far in OC users. Therefore, we investigated possible different effects of "quasi follicular phase-based" versus "quasi luteal phase-based" strength training (qFT and qLT) on strength parameters and muscle volume in oral contraceptive users.

Methods: 16 healthy untrained or moderately trained women (age: 22.5 ± 2.3 yrs, height: 167.2 ± 6.4 cm, weight: 64.0 ± 9.1 kg) using OC completed a strength training program of the m. quadriceps femoris for each leg on the Leg Press for 3 menstrual cycles (approx. 12 weeks). The subjects were divided into group A and group B. Group A performed qFT with the right leg and qLT with the left leg and vice versa for Group B. qFT was organized 4 times a week in qFO and once in qLU, and qLT was organized 4 times a week in qLU and once a week in qFO. Blood samples were taken on 11th day in qFO and on 25th day in qLU of the menstrual cycle to analyze values of E2, progesterone (Prg), FSH, LH, total testosterone (tT), free testosterone (fT), IGF-1, DHEA-S and hGH. Maximum isometric force (Fmax-iso) was measured for each right and left leg prior to, during (2 times per cycle), and after training. Muscle diameters (Mdm) were measured by means of ultrasound for M. quadriceps prior to and after training, and sum of Mdm of M. rectus femoris, M. vastus intermedius and M. vastus lateralis was calulated.

Results: E2, LH, FSH, tT and DHEAs were significant higher in qFO as compared to qLU, and Prg, hGH, IGF-1 and fT were not significantly different between the two phases. Fmax-iso increased significantly by 24.9 ± 13.6 kg (+29.0 %) after qFT and by 25.6 ± 11.9 kg (+31.9 %) after qLT without any difference between the effects of qFT and qLT. Mean value of Mdm increased significantly by 0.41 ± 0.43 cm (+6.8 %) after qFT and by 0.49 ± 0.41 cm (+8.5 %) after qLT without any significant difference between both interventions

Conclusions: Both, qFT and qLT showed significant effects on muscle strength and muscle diameter after 3 months of intervention without any differences between both interventions. This is in contrast to findings in women without use of oral contraception, who clearly showed a higher increase of muscle strength and muscle diameter after FT as compared to LT. The underlying mechanisms for these different effects have to be analyzed in further studies.

EXERCISE HABITS THROUGH THE LIFE IN THE COMMUNITY-DWELLING JAPANESE ELDERLY

KOZAKAI, R., DOYO, D., KIM, H.Y., ANDO, F., SHIMOKATA, H.

NATIONAL CENTER FOR GERIATRICS AND GERONTOLOGY

Introduction: Physical activity is one of the most important health behaviors especially in later life. Previous studies suggested that sports activities early in life affected to the exercise habits for the future. However, little is known about the participation, type and transition of exercise habits through life in the elderly.

Purpose: The purpose of the present study was to describe the exercise habits across the life course in the community-dwelling Japanese elderly.

Methods: The subjects consisted of 523 males (aged 70.0±6.6 years) and 461 females (aged 69.8±6.7 years). They were the participants aged 60 years and over in the 4th study of the National Institute Longevity Sciences - Longitudinal Study of Aging (NILS-LSA). Exercise habits were assessed using questionnaire and interview by trained staff. The subjects were asked to answer the type, frequency and duration of their exercise habits at the age of 12 years and later. Physical exercise or sports that were engaged in at least once a week and for 20 minutes over 1 year were defined as exercise habits. The life course was divided into five age periods: 10s (teens); 20s (20-29

years); 30s (30-39 years); 40s (40-59 years), 60s (60 years and over). The participation rate in exercise habits was calculated as the percentage of subjects who engaged in exercise by each age period. The Chi-square test was used to examine the difference between males and females. The relationship between participation rate in 60s and that in each 10s-40s was analyzed using the McNemar test.

Results: The participation rate in exercise habits in 10s, 20s, 30s, 40s and 60s were 59.5%, 33.1%, 29.6%, 44.6% and 65.4% in males, while 43.0%, 6.3%, 13.5%, 44.0% and 57.1% in female, respectively. Percentage of males who had exercise habits was significantly larger than that of females through the life excepted in 40s ($p<0.05$). A large drop in the percentage of participation in exercise occurred between 20s among females. The percentage of subjects who had never participated in exercise was 11.1% in males and 20.8% in females. The subjects who had exercise habits in each of 10s, 20s, 30s and 40s were more likely to participate in exercise in 60s in both genders ($p<0.05$). The most males had exercise habits either across life course or only in 60s. The most females had exercise habits in 40s or over for the first time. The popular exercise was totally different in males and females and by each age period. The most popular exercise in 10s was baseball in males and volleyball in females, while that in 60s was walking in both males and females.

Conclusion: Males or people who had exercise habits in early in life were more likely to participate in exercise. There were also the people who started exercise activities in middle-aged and elderly. The popular exercise was different by sex and each age period. These results may help to discern how physical activity behaviors are constituted in later life.

SHARED LEADERSHIP IN TOP SPORTS COACHING: FROM RHETORIC TO REALITY?

HEMMESTAD, L.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Sports coaching is a complex domain of professional practice which until recently has been informed mainly by approaches modelled within the natural sciences paradigm (Gilbert & Trudel, 2004; Stelter, 2005). Due to the complexity of the sports coaching field it has been argued that it rather should be viewed as an essentially pedagogic and educational endeavour (Jones, 2007). The traditional approach has also been criticised for the hierarchical power relationships between coach and athletes, and for not allowing athletes greater equity. Although recent studies have begun to emphasise the importance of empowerment and athlete autonomy (cf. Jones & Standage, 2006), there are few empirical longitudinal studies in the sport coaching field on this topic.

The purpose of the study was to give insight into and a better understanding of how such ethos can be realistically viewed within the top sport coaching process. The analysis builds on a longitudinal in-depth case study with a National Team during two seasons. In addition more than 20 qualitative interviews with coaches and players were conducted.

The case is especially interesting because in rhetoric, it builds on a more pedagogical-philosophical thinking, than the more traditional technical approach. The coaching philosophy in the team emphasise the importance of shared leadership and autonomy to the players.

Even though the notion of shared leadership and allowing more autonomy to the athletes may be attractive the study also highlights some critical aspects to such democratic ethos. Especially the uneasy interplay between power relations is addressed. The study gives insight into constraints and possibilities with shared leadership, and how the team worked to overcome the gap between idealism and reality.

The positive change both in player involvement processes and in the communication processes seemed possible because both players and coaches were self-reflective and focused on personal growth. Another crucial dimension was that the team actively and critically engaged with the question: ¨What can make us better? This was regarded not only a technological question but much more a pedagogical one.

STUDYING THE MAP-READING PROCESS AS A ECOSYSTEM; MAP-READING REGARDED AS A WHOLE, COMPRISING THE MAP-READER, THE MAP AND THE TERRAIN

SIGURJONSSON, T.

HEDMARK UNIVERSITY COLLEGE

Introduction: A main intention of the data collection in orienteering research, based on ecosystem thinking, is to provide data that approximately mirrors the performer's experiences during the movement with a map in the terrain. Through this point of view I attempt to understand meaningful, specific relationships that are present in a experience in particular situations in a specific contexts. With Gibson's ecological perspective (1979) I got the opportunity to focus on this natural context where the environment is considered to be rich and meaningful information that a map-reader, based on his/her perception, can pick out.

Methods: In the design of data collection my goal was to obtain access to the participants lived experience with the map-reading ecosystem 'without' disrupting the ongoing process. To illuminate my specific research the collection of data was carried out in a qualitative methodological approach manner. The empirical material was generated from audio and video-taped fieldwork in a naturalistic setting

with follow-up conversations where specific situations from the fieldwork were watched on a television. The techniques of head-mounted-camera were used.

Results: The data collection gave some major challenges and the empirical study revealed to me that it is important to develop methods based on the phenomenon to be studied so that it should not be contradiction between method and phenomenon. This demanded that the selected methods had to be used to decide the method's ability to provide the real-world situation in orienteering justice. Another important factor is to obtain a deviation in the selection of participants to produce a variation in aspect ratio to illuminate the problem formulations.

Discussion: Through this concept I got the opportunity to collect data from orienteering in natural real world settings where my role was in the background although I now and then had to appear in the forefront, for example when the informants did not understand the task at all.

The contribution of this method is that it gives a clear advantage in the way that the camera focuses on the environment rather than the informant. It reduces self-awareness and reinforces the psychological into the initial events (Omodei & McLennan, 1994; Unsworth, 2001). An unequivocal benefit with the use of head-mounted camera is that it provides images from the same visual perspective that the bearer has

Through my research I have experienced the methodological challenges in studying of a phenomenon in natural real world setting. It would be interesting to discuss further with the participant's on the ECSS.

SPREAD IN RUNNING TIMES AS A MEASURE OF ORIENTEERING COMPLEXITY FOR BEGINNERS

OTTOSSON, T., ERFORS, A.

KRISTIANSTAD UNIVERSITY COLLEGE

With few exceptions (e.g., Ottosson, 1987; Sigurjónsson, 2007), how beginners in orienteering manage the tasks they are presented is far from well researched. In Swedish orienteering clubs, beginner instruction is normally administered according to a well established pedagogy, most often talked about as a ladder of difficulty. This system builds on many years of collected experiences of instruction, and appears to be generally effective. However, if this pedagogy could be validated by empirical data, its application would be even further motivated. On the other hand, data could, alternatively, point to a more or less different ranking of orienteering difficulties, and thus provide indications of need of revisions of the pedagogy. In this study, split times between control points on courses for children (aged 10 and younger) on regular orienteering events provide data for analysis. It is assumed that more difficult legs would result in greater spread in running times. In other words, a correlation between complexity of orienteering tasks and spread in running times is hypothesised. Different measures of spread are examined, and related to the orienteering tasks accomplished by the children. Greater spread is interpreted as greater complexity of a task, and the pattern of measures of spread, as related to characteristics of the orienteering tasks, is discussed.

WHO STOPS – WHO CONTINUES? A STUDY OF PARTICIPATION IN CLUB SPORTS DURING ADOLESCENCE.

THEDIN JAKOBSSON, B., ENGSTRÖM, L.M.

THE SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES

Nowadays most Swedish children are members of a sports club at some time during their childhood or teenage years. Participation is greatest at the age of twelve. By the end of the teenage years many have ceased to be club members. The overall aim of the study is to investigate changes in sports participation during adolescence. The following questions are of special interest: What characterises those who leave sport and those who continue? Which sports contribute to the retention of participants and which do not? The survey is part of a Swedish multi-disciplinary project called School–Sport–Health 2001, 2004 and 2007, in which 600 girls and boys from Years 3, 5 and 9 participated. It is based on self-reported questionnaires relating to social background, physical education and leisure time activities. The results have been analysed by SPSS, a computer program designed for statistical analysis. The results indicate that about 60 percent of the survey groups are members of sports clubs in Year 9, which is 20 percent less than in Year 6. Boys are more often members than girls, and report a higher training intensity. The most popular club sports in both Years 6 and 9 are horse riding for girls and football for boys. Members of sports clubs report higher grades in Year 9 and often choose academic programmes at upper secondary school. The conclusion is that teenagers who continue to participate in club sports seem to achieve high grades in the subject Physical Education and Health, have a high merit rating in Year 9, are prepared for upper secondary school studies and regard themselves as physically active. The presented data will be discussed from a critical pedagogic perspective in the context of existing research, with a focus on social and cultural resources (values and capital) and participation in organised sport for children and youth.

STUDY ON THE RELATIONSHIP BETWEEN ENERGY EXPENDITURE OF STUDENTS AND TEACHING METHODS OF MOTOR AND SPORTS ACTIVITIES IN PRIMARY SCHOOL IN ITALY

CARLOMAGNO, N., LIPOMA, M., D'ELIA, F., BALDASSARRE, G., SGRÒ, F., SANGIORGIO, A., SIBILIO, M.

(1) UNIVERSITY

Introduction.

The latest indications from the Ministry of Education recall the need that experiences leading to a correct and healthy lifestyle, will be in the curriculum of primary school (PS). They include the prevention of diseases related to hypokinesia, through the enhancement of school and extra-school motor and sport experiences (Ministerial Directives, 2007). In PS the methodological choices are left to the teachers who decide the type of motor and sports activities to be proposed to the students, referring to the objectives and educational programmes and the Directives of the Ministry. The type of motor activity and the energy expenditure (EE) associated with it then depend only on the methodology of the teacher.

Objective.: The objective of this research was to analyze the relationship between teaching methods of motor and sports activities and EE in classrooms of a PS. The study was to determine the difference in EE between the different teaching approaches used independently by each PS teachers and the use of a common teaching methodology.

Methods: The research involved 18 classes for a total of 260 pupils in a PS of Naples. For each pupil has been prepared in advance an information grid collecting data on age, weight, height, the dietary habits, motor or sport practiced actions and some details about life-styles. 18 teachers have been entrusted with the task of leading a lesson in 45 minutes on a common theme while a calorimeter, put on the arm of the students, was measuring energy expenditure during the lesson, through a system of multi-sensor monitoring. Subsequently formative activities, conducted by the University of Salerno and the University Suor Orsola Benincasa of Naples, were carried out to give to the 18 school teachers a shared methodology for the motor activity. In the second phase of the work teachers were asked to propose the activity to the students on whom the calorimeters were set.

Results: The acquisition and the processing of the data using the software Sense Wear and the comparison of these data made possible to measure and compare the differences in EE in the presence of different approaches and in the presence of a single goal, while a greater homogeneity was found when the same methodology was used by teachers. In perspective, the adoption of shared didactic methodologies and protocols for motor activities will allow to pursue the objectives of the Ministerial Directives related to children health.

REDESIGNING THE 'SPORT MULTIMEDIAL' E-LEARNING APPLICATION

LESER, R., BACA, A., EDER, C., KARALL, E., MIKO, C., UHLIG, J.

CENTRE OF SPORT SCIENCE, UNIVERSITY OF VIENNA

'Sport Multimedial' is an e-learning platform designed to make theoretical sports-scientific content available within an interdisciplinary network so this content can be used alongside with and as a complement to practical sports courses at the Faculty of Sport Science of the University of Vienna (Baca, Kolb & Eder, 2009). This web application has been in practical use for about three years and was added to the curriculum during that period. Current formative evaluation procedures show, however, that students and instructors have not accepted the platform to the degree desired. This paper discusses known reasons for this and proposes approaches to solutions for the planned further development of the system.

The platform is currently based mainly on a cognitivistic approach to learning. The subject matter is presented using various media (text, video, animation, etc.) and the primary goal is simply to convey information. Particularly in motor learning, such components as experimentation and trying things out are also meaningful in the context of a constructivist approach. Target-oriented implementation of interactive elements is to place more emphasis on these aspects in the future. In this context, enhanced functions for communication between students and between students and instructors are being planned, too. With these functional expansions to the learning platform, the authors hope above all to acknowledge the primacy of situated learning. It is hoped that this will lead to an intensified transfer of knowledge whose effect will last far beyond the teaching situation.

Although it was desired to use Sport Multimedial in all courses at the Faculty of Sport Science, this turned out to be quite difficult because it was not possible to motivate enough instructors of practical courses to join the project. The authors feel that this is mainly due to the extra time instructors need to spend before they can begin to use the medium, while a possible added value for their courses will not materialize until later on.

For the next project phases, the authors succeeded in motivating two instructors of practical courses, who are responsible for many of the relevant courses, to join the inner circle of the development team. These persons are employed by the Faculty of Sports Science as senior lecturers for tasks that transcend pure teaching. Accordingly, they take over coaching and quality monitoring activities within the Sport Multimedial project. As a first step, the courses of these two senior lecturers will be adapted to the new concept. This is expected to cause a snowball effect that the students visiting courses integrated in the system should transfer to practical courses not yet integrated.

IS-SM04 Prevention of Sport Injuries (ECSS Position Statement Symposium)

PREVENTION OF SPORT INJURIES I/IV

STEFFEN, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

To maximize the health benefits of sports and exercise and minimize the direct and indirect costs associated with injuries, developing and adopting injury prevention strategies is an important goal. The aim of this ECSS consensus paper on injury prevention is to review current evidence on injury prevention methods and training programs aimed at reducing the most common or severe types of acute injuries. The target audience is everyone involved in protecting the health of the athlete, i.e. coaches, referees, medical staff, sports governing bodies, as well as athletes themselves. Effective sports injury prevention requires successful implementation of efficacious interventions. This paper reviews the main mechanisms and risk factors for acute injuries to the head, shoulder, elbow, hand/wrist, groin, thigh, knee and ankle, as well as the evidence supporting various strategies to prevent them. Approaches that have been proven successful include: 1) using equipment designed to reduce injury risk, 2) adopting the rules of play, and 3) specific exercise programs developed to reduce injury risk. Sports organizations should adopt available injury prevention strategies as part of their policies.

[Please note: This paper is part of the ECSS Position Statement: Prevention of Sport Injuries, K. Steffen, T.E. Andersen, T. Krosshaug, W. van Mechelen, G. Myklebust, E. Verhagen, R. Bahr and will be published in the European Journal of Sport Science (EJSS)]

IS-BC01 Satellite cells and regulation of muscle mass

THE BEHAVIOUR OF SATELLITE CELLS IN RESPONSE TO LOADING AND UNLOADING IN YOUNG AND OLD

MACKEY, A.

BISPEBJERG HOSPITAL AND UNIVERSITY OF COPENHAGEN

Of the many different populations of cells residing in adult skeletal muscle, satellite cells are critical where processes of muscle growth, hypertrophy and repair are concerned. Increased life expectancy and associated sarcopenia have resulted in an increased effort to understand the function or dysfunction of satellite cells with ageing. It has now repeatedly been shown that heavy strength training and myofibre injury lead to proliferation of this cell population, in healthy young and old individuals, to varying extents. The purpose of these new myonuclei is to maintain an expanding cytoplasm or new muscle tissue in the case of hypertrophy or repair, respectively. Furthermore, it is apparent that satellite cells are subject to a strong regulatory influence by the niche in which they reside. Studying satellite cell activity with the aid of different markers, such as CD56 and Pax7, in the context of the local environment thus provides further insight into the behaviour of satellite cells in response to different stimuli. To provide some balance to the popular heavy loading models, muscle unloading is an interesting model for monitoring the behaviour of satellite cells. In addition, the ability to introduce pharmacological agents, such as anti-inflammatory medication and growth factors, directly into the muscle contributes further to the relatively limited selection of tools available for the study of satellite cells.

SATELLITE CELLS AND THE MYOGENIC RESPONSE TO DAMAGING EXERCISE

RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

It is well documented that satellite cells play an important role in the regeneration process after muscle damage in mammalian skeletal muscle [2]. In animal models, severe muscle damage results in necrosis of muscle fibres and an inflammatory response is initiated. In the repair process the satellite cells are activated and start to proliferate. Later, a phase of differentiation and fusion of satellite cells leads to the formation of new myotubes that replace the once lost in necrosis. In the case of exercise-induced muscle damage, it is probably only segments of fibres that undergo necrosis and need to be replaced. The importance of satellite cells for full regeneration is demonstrated in studies where satellite cell activation is reduced [1].

Although the role of satellite cells in regeneration after damaging exercise is well described in animal models, the events of regeneration have so far not been shown in human muscles. The main reason is probably that necrosis rarely occurs after muscle-damaging exercise in humans. However, in a recent experiment we have observed extensive necrosis after high-force eccentric exercise with the elbow flexors [5]. Analysis of repeated biopsies obtained in the days and weeks after exercise demonstrated a similar regeneration process as earlier described in animal models. The different phases of the satellite cell response can be followed by using markers for proliferation and differentiation. A number of different proliferation markers can be used, but so far the myogenic regulatory factors have been used most extensively to mark both proliferation and differentiation phases. Also in studies with no apparent fibre necrosis, activation of satellite cells has been indicated [3, 4]. The role of the satellite cells in recovery processes without necrosis is less clear, but addition of nuclei may help the reconstruction of damaged structures within surviving fibres as well.

The inflammatory process initiated after severe muscle damage seems to be important both for removing debris and in the activation of satellite cells [6]. Consequently, administration of anti-inflammatory drugs may actually hamper regeneration after muscle damage. So far this potentially negative effect of anti-inflammatory drugs on the recovery processes is reported in animal models [1]. In humans, administration of NSAIDs reduced the increase in satellite cells after running exercise [4]. Surprisingly, in our recent study with extensive necrosis, the administration of a COX-2 inhibitor did not seem to affect the satellite cell response detectably [5]. Consequently, more studies are needed to further explore the interaction between the inflammatory process, activation of satellite cells and the orchestration of the recovery processes in humans.

THE BEHAVIOUR OF YOUNG AND OLD HUMAN MYOBLASTS

HARRIDGE, S.

KING'S COLLEGE LONDON

Twenty years ago Carlson and Faulkner (1989) made the interesting observation that if a muscle from an aged rat was transplanted into a young host the recovery potential of that muscle, in terms of mass and force production, was similar to that of a transplanted young muscle. Conversely, both young and old muscles recovered less well if they were transplanted into an aged as opposed to young host. This study provided the first evidence of a negative of the systemic environment, rather than on the tissue itself, on skeletal muscle regen-

eration. More recently these observations have been supported by work on parobiotic mice, animals which share a conjoined circulation. Using this model, recovery to a damaged older muscle was markedly improved if the aged animal shared its circulation with a younger animal (Conboy et al. 2005). Recent studies (Carlson et al. 2008) suggest that this age related impairment to recovery from damage relates to changes in a number of signalling pathways (Notch, TGF-beta, pSmad3). These pathways regulate the proliferation and the myogenic commitment of satellite cells which are required not only for repair, but also for adaptation and hypertrophy. Whilst age-related impairments in the recovery of muscle from damage have been demonstrated in rodent studies, human exercise studies have shown that even the muscles of very elderly people are able to increase satellite cell number and hypertrophy in response to overload. We have recently used a primary cell / serum model to study the effects of the age of systemic environment on the behaviour of human cells extracted from muscle biopsies in culture. We have shown that committed myoblasts show similar abilities to both proliferate and differentiate when cultured in either a young or old serum. Furthermore, the cell itself (i.e. whether it originates from a young of elderly donor) shows no age-dependent behaviour. These findings would therefore suggest that a sufficient number of satellite cells are able to successfully progress through the myogenic lineage and can contribute to adaptation, even in an apparently hostile aged milieu.

THE REGENERATIVE POTENTIAL OF HUMAN SKELETAL: EFFECTS OF EXERCISE ON TELOMERES.

PONSOT, E.

ÖREBRO UNIVERSITY

The length of DNA telomeres is an important parameter of the proliferative potential of tissues. Recent data also suggest that the rate of telomere shortening is accelerated by external factors such as oxidative stress. A recent study reported abnormally short telomeres in skeletal muscle of athletes with exercise-associated fatigue. This important report raises the question of whether long-term practise of exercise might have deleterious effects on muscle telomeres, and thus on skeletal muscle tissue regenerative capacity.

Recent data suggest that skeletal muscle telomere length is not altered during healthy aging as no significant differences in telomere are found between healthy active old men and women and young men and women with comparable physical activity level (Ponsot et al., 2008). In addition, in well-trained athletes with long history of strength training but free from symptoms of overtraining, there are no deleterious effects on telomeres, and on the contrary, telomere length in these subjects tend to be longer than in subjects with no history of strength training (Kadi et al., 2008). In accordance with data found in skeletal muscle, recent findings suggest that physical activity can be a positive regulator of telomere length in leukocytes (Cherkas et al., 2008; Ludlow et al., 2008). These results set the basis for a new hypothesis suggesting that, rather than being deleterious, well-designed exercise training may have a positive effect on in vivo regenerative capacity of skeletal muscle in healthy individuals.

EXERCISE TRAINING, SATELLITE CELLS AND THE REGENERATIVE POTENTIAL OF SKELETAL MUSCLE

KADI, F.

ÖREBRO UNIVERSITY

Human skeletal muscle is a dynamic tissue characterised by a remarkable ability to continuously respond to environmental stimuli. Experiments in humans clearly show the great ability of skeletal muscle to regenerate after loading or injury or both. Satellite cells in human skeletal muscle enter proliferation in response to light and heavy resistance training or endurance exercises both in young and old individuals. Enhancement of satellite cell pool in response to training is another health benefit of exercise. The proliferative capacity of skeletal muscle is influenced by the length of DNA sequences located at the end of chromosomes called telomeres. A dramatic shortening of telomeres is associated with a reduction in tissue regenerative potential. Rather than considering skeletal muscle as a stable tissue in term of regenerative events, muscle biologists start to learn that under harmful circumstances an abnormal shortening of telomeres might occur and that when training is properly performed the telomere length can be positively regulated. No doubt that new mechanisms relating the effects of exercise on the regenerative capacity of skeletal muscle and the regulation of telomere length will emerge in the near future.

INFLUENCE OF EXERCISE VARIATION ON THE RETENTION OF A PACING STRATEGY

MAUGER, A., JONES, A., WILLIAMS, C.A.

EXETER UNIVERSITY

Background: In competitions where time to completion is the measure of success, pacing strategy exerts an important influence on performance. The Theory of Teleoanticipation and the Central Governor Model, proposes that a pacing strategy is set in a feedforward manner, based on distance or duration, prior to the onset of an exercise bout. Prior experience of an exercise bout allows the construction of a pacing schema, which is utilised for subsequent, similar bouts of exercise. During exercise, distance or time remaining is judged by an 'internal clock' that is located in the brain. It is proposed that this timing mechanism works in a scalar fashion, using relative rather than absolute quantities. Despite the apparent importance of the scalar clock to the maintenance of a pacing strategy, knowledge in this area is presently limited.

Aims: To establish whether the introduction of an exercise bout of different distance, in the absence of distance feedback, would affect the retention of the pacing schema stored from a prior exercise bout. Furthermore, to identify whether the internal clock has an ability to calibrate to absolute distance, and whether this mechanism is disrupted by an exercise requiring a different pacing strategy.

Methods: Sixteen highly-trained male cyclists were randomly split into a control (CON) or experimental group (EXP) and completed four time trials (TT) of two different distances (2x4 km and 2x6 km) in varying orders, separated by 17 minutes. The participants in the CON group completed both distances in a sequential order (i.e. half performed 4 km, 4 km, 6 km, 6 km, and the other half performed 6 km, 6 km, 4 km, 4 km). The EXP group completed both distances in a variable order (i.e. half performed 4 km, 6 km, 4 km, 6 km, and the other half performed 6 km, 4 km, 6 km, 4 km). During each TT, power output, VO2 and heart rate were recorded. Participants in both groups were asked to call out their RPE for every km they thought they had completed.

Results: No significant differences were found between or within groups for completion time or PO ($p > 0.05$). The CON group showed a significant improvement in their estimation of distance completed in both the 4 km (24.6 ± 18.2 % vs. 8.2 ± 5.5 %) and 6 km (15.2 ± 7 % vs. 8.6 ± 3 %) distances ($t7 = 2.791$, $t7 = 3.118$, $p < 0.05$). No significant differences in distance estimation were observed in the EXP for either of the TT distances ($p > 0.05$).

Conclusion: The primary finding of this study is that participants who did not receive an exercise interruption displayed a significant improvement in their judgement of distance completed, despite no improvement in completion time. This suggests that a learned pacing schema is robust and not negatively affected by subsequent pacing variation and can be retrieved when required. The internal clock shows an ability to be calibrated to absolute distance, although this does not improve performance.

UNRAVELLING THE MECHANISMS OF EARLY-MORNING CEREBRAL EVENTS: THE IMPORTANCE OF DIURNAL VARIATION IN ORTHOSTATIC TOLERANCE

LEWIS, N.C.S., LUCAS, S.J.E., GRANT, E.J.M., ATKINSON, G., JONES, H., AINSLIE, P.N.

LIVERPOOL JOHN MOORES UNIVERSITY, AND THE UNIVERSITY OF OTAGO

Introduction: The most common form of syncope is explained by vasovagal mechanisms. Hypotension during pre-syncope is probably precipitated by sympathetic nervous system withdrawal (Mosqueda-Garcia et al., 1997) but loss of consciousness is caused by cerebral hypoperfusion. The risk of neurally-mediated syncope peaks in the morning (van Dijk et al., 2007), coinciding with the time of resuming upright posture and the beginning of physical activity. It is critical that the relative importance of orthostatic- and exercise-related challenges are unravelled to gain an understanding of why cerebral ischemia events peak in the morning. This study is the first to examine the extent to which orthostatic-induced reductions in blood pressure (BP) and cerebral blood flow may differ with time of day. It was hypothesised that orthostatic tolerance is impaired in the morning due to a diurnal failure to maintain BP and thus cerebral hypoperfusion.

Methods: Nine male and six female participants aged 27±5 yrs (mean±SD) completed two trials starting at 06:00 h and 16:00 h. Continuous beat-to-beat measurements of cerebral blood flow velocity (CBFv; transcranial Doppler), BP (Finometer), heart rate (HR), and end-tidal PCO2 were obtained during 15 min of supine rest and during 60° head-up tilt with lower body negative pressure in 5-min increments of -10 mmHg, until pre-syncope. Pre-syncope was terminated on participants' request due to subjective symptoms associated with fainting, or when systolic BP reduced to <80 mmHg for more than 10 s. Data were analysed using paired t-tests and reported as mean±SD.

Results: During supine baseline, mean BP was 5±1mmHg higher, and CBFv was 7±3 cm/s lower in the morning compared with the afternoon ($P<0.05$). Baseline measurements of HR and end-tidal PCO2 did not differ between times of day ($P>0.05$). Time to pre-syncope occurred faster in the morning (1634±633 s) than in the afternoon (1988±475 s) with the 95% confidence limits for the mean difference between times of day being 25 to 684 s ($P=0.04$). Despite the diurnal variation at baseline, mean BP, CBFv, HR and end-tidal PCO2 at pre-syncope did not differ significantly between times of day ($P>0.05$).

Discussion: A marked reduction in orthostatic tolerance is evident in the early morning, resulting in an earlier onset of pre-syncope. Although the sequence of haemodynamic adjustments is similar between the two times of day, the adjustments are accelerated in the early morning, presumably via impairment in the bar reflex control of BP at this time of day. This study shows that postural changes independent of an exercise effect can increase the risk of vasovagal syncope in the morning in young, healthy and physically-fit people.

THE EFFECT OF BICARBONATE INFUSION IN CEREBRAL METABOLISM DURING MAXIMAL EXERCISE

VOLIANITIS, S., RASMUSSEN, P., SEIFERT, T., SECHER, N.H.

AALBORG UNIVERSITY

Exercise lowers the cerebral metabolic ratio of O2 to carbohydrates (glucose + ½ lactate). Metabolic acidosis increases cerebral lactate uptake and exacerbates the cerebral metabolic ratio in vitro. However, the influence of pH on cerebral lactate uptake and the cerebral metabolic ratio during exercise in humans is not known.

PURPOSE: To evaluate the influence of pH on cerebral metabolism during maximal exercise. METHODS: Sodium bicarbonate (Bic, 1 M; 350-500 ml) or an equal volume of saline (Sal; 1 M) was infused intravenously at a constant rate during a '2,000-m' maximal ergometer row in six male oarsmen (23 ± 2 yrs). Comparisons between the two conditions were made using two-way ANOVA with repeated measures. RESULTS: During the Sal trial, pH decreased from 7.41 ± 0.01 at rest to 7.02 ± 0.02 but only to 7.36 ± 0.02 ($P < 0.05$) during the Bic trial. Arterial lactate increased to 21.4 ± 0.8 mM (mean ± SEM) and 32.7 ± 2.3 mM during the Sal and Bic trials, respectively. The arterial-jugular venous (a-v) lactate difference increased from -0.03 ± 0.01 mM at rest to 3.2 ± 0.9 mM ($P < 0.05$) and 3.4 ± 1.4 mM ($P < 0.05$) following the Sal and Bic trials, respectively. The cerebral metabolic ratio decreased equally during the Sal and Bic trials from 5.8 ± 0.6 at rest to 1.7 ± 0.1 and 1.8 ± 0.2, respectively.

CONCLUSION: The enlarged blood-buffering capacity after infusion of Bic attenuated the metabolic acidosis but did not affect the cerebral lactate uptake or the cerebral metabolic ratio during maximal exercise.

EFFECTS OF PRIOR EXHAUSTIVE LEG OR ARM EXERCISE ON SUBSEQUENT PERFORMANCE, POWER AND EMG ACTIVITY IN A DIFFERENT MUSCLE GROUP

GABE BELTRAMI, F., DE GROOT, R., RAUCH, L., TUCKER, R., RAE, D.E., NOAKES, T.D.

UNIVERSITY OF CAPETOWN

Introduction: A prior bout of exhaustive exercise is known to result in early exhaustion being reached during a subsequent bout of maximal exercise. Much of the research to date has examined peripheral factors for this phenomenon. Therefore, the aim of this study was to investigate the contribution of central regulation on the performance of maximal exercise preceded by a bout of exhaustive exercise using a different muscle group.

Methods: Ten healthy men (5 well-trained cyclists and 5 well-trained canoeists) were recruited for this study and all completed two exercise trials. In trial 1, subjects performed an incremental leg ergometry test to exhaustion (LEG A), followed 15 minutes later by an incremental arm ergometry test to exhaustion (ARM B). In trial 2, the order was reversed (ARM A followed 15 minutes later by LEG B). The two trials were separated by at least 3 days and the order in which the subjects performed the trials was randomised. Time to exhaustion (TE), power output (PO), heart rate (HR), rating of perceived exertion (RPE), oxygen consumption (VO2), ventilation rate (VE), plasma lactate (LA) and electromyography (EMG) of two lower (rectus femoris and vastus lateralis) and two upper limb (triceps and biceps) muscles were measured during all trials.

Results: During the A trials, subjects reached exhaustion faster and at a higher PO during legs compared to arms. While HR and RPE were similar in the leg and arm tests at exhaustion, VO2 ($p = 0.018$) and VE ($p = 0.008$) were lower in the arm test. Performance during ARM B was unaffected by prior LEG A. However, prior ARM A significantly reduced TE ($p = 0.011$) and peak PO ($p = 0.011$) during subsequent LEG B. There were no changes in maximal VO2, HR, RPE, VE and LA between trials A and B of each muscle group. LA was higher at the beginning of LEG B ($p < 0.001$) and ARM B ($p = 0.001$) exercise compared to their respective A trials. Prior LEG A affected subsequent ARM B HR for the first 40% of the trial. During LEG B, however, HR differed only at the start and 20% of the test. EMG increased linearly during all the trials and maximal EMG activity measured during the tests was only 55% of previous MVC. RPE rose linearly during all tests, regardless of different levels of LA and HR. None of the measured physiological/neuromuscular variables measured showed a plateau at exhaustion.

Conclusion: Prior arm exercise reduced peak power output during a subsequent bout of exhaustive leg exercise without altering the physiological or EMG variables measured in this study. In contrast, prior leg exercise did not alter peak power output during subsequent arm exercise. These results suggest that during the tests RPE was set in anticipation, being independent of the amount of muscle mass activated, HR or LA. These data are difficult to interpret according to traditional peripheral models of exercise fatigue and deserves further investigations.

IMPACT OF TRAINING STATUS ON MAXIMAL OXYGEN UPTAKE CRITERIA ATTAINMENT DURING CYCLING

CHRISTIE, C.

RHODES UNIVERSITY

Objectives: The aims of this study were to assess whether training status influenced maximal physiological and perceptual responses and whether certain maximal criteria were more sensitive for individuals with different levels of training. Methods: Females who were either trained (N = 10) or untrained (N = 10) underwent a maximal cycle ergometer test to assess whether the criteria to indicate VO2 max were training-specific. Results: Expectedly, VO2 max was significantly higher in the trained (50.09 mlO2.kg-1.min-1) compared to the untrained group (35.21 mlO2.kg-1.min-1) while the oxygen uptake plateau criterion was met by only 40% of the participants. Peak workload (W) was significantly higher (234 W compared to 174 W) and total test time significantly longer (7 minutes compared to 5 minutes) in the trained group. Peak lactate values did not reach maximal criteria and on completion of the test were not significantly different between the groups (7.8 mmol.L-1 in the trained group and 8.1 mmol.L-1 in the untrained group). Likewise, maximal heart rates, respiratory exchange ratio (RER) values and ratings of perceived effort were not different between the groups. Noteworthy is that none of the subjects achieved all of the criteria indicating a maximal effort. The criteria most achieved in both samples were RPEmax and RERmax with the latter being the most attained in the untrained group and RPEmax being mostly attained by the trained group. Conclusions: The criteria used to indicate attainment of VO2 max may be limited and may differ when comparing a heterogeneous training sample. Although VO2 max was significantly higher in the trained group, all the other responses were similar. However, the number of trained and untrained subjects reaching particular criteria was different suggesting that certain criteria may be more sensitive for individuals with different levels of training.

HIGH INTENSITY EXERCISE <HIT> IN CHILDREN: RESULTS FROM DIFFERENT DISCIPLINES

SPERLICH, B., HAEGELE, M., ACHTZEHN, S., DE MAREES, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE, THE GERMAN RESEARCH CENTRE OF ELITE SPORT, GERMAN SPORT UNIVERSITY COLOGNE, GERMANY

INTRODUCTION: Recent studies of high intensity training (HIT) in different endurance related sports (GIBALA et al. 2007, FAUDE et al. 2008, MacMILLAN 2004) with adult athletes document that HIT leads to similar or even the same physiology adaptations in respectively shorter exercise time compared to high volume training (HVT). Current publications show positive effects on mitochondrial efficiency and lipid metabolism after HIT (DAUSSIN et al 2008). Studies regarding HIT in children are rare. The goal of the study was to compare HIT vs HVT in two different disciplines with different metabolic demands on physiological and performance related parameters in children.

METHOD: Two studies in swimming (A, n= 27, 9-12yrs) and soccer (B, n=19, 14 yrs) were conducted: In both studies the participants were divided into two groups in order to compare the effects of HIT vs HVT. A: Before and after the training intervention maximal oxygen uptake and power output at 4 mmol/L lactate (Lac) were assessed. All participants performed a 2km-test, a 100m test with logging of post lactate kinetics as well as a 6x50m interval-test in a 50m pool. B): Before and after the mesocycle maximal oxygen uptake was assessed. All participants performed a 1km run, as well as a 20m, 30m and 40m sprints. Jumping performance was measured in a drop and counter movement jump. RESULT: A): Training: Workload for HIT was set at ~93% of personal best time corresponding to average lactate values of 5.2±1.2 mmol/l Lactate. HVT was set at 83% of personal best time with average lactate values of 2.3±0.5 mmol/l Lactate. HIT training volume was set at 57x50m, 57x100, 15x200m and 3x300m intervals (total: 27,3 km, time per session:60 minutes). HVT training volume was: 89x100m, 62x200m, 53x300m, 19x400m and 4x800m intervals (57,3km, time per session:90 minutes). No statistical differences were found for any physiological variable between the groups. Competition performance showed an increase of 9% for HVT and 14.3% for HIT.

B): Mean HR during HIT was 25.3% at 90-100% HRmax, 39.3% at 80-90% HRmax, 20.7% at 70-80% HRmax, 11.6% at 60-70% HRmax and 3.2% <60% HRmax. For HVT HR was set at 0.8% at 90-100%, 27.0% at 80-90% HRmax, 42.5% at70-80 HRmax, 9.7% at 60-70 HRmax and 9.9% below 60% HRmax. Mean Lac-values in HIT were 8.74±3.20mmol/L Lac and 2.17±1.09mmol/l. Oxygen uptake increased depending on recovery time.

Summary: The results indicate that HVT is not necessarily beneficial as trainings strategy compared to HIT in swimming and soccer at the age of 9-14 years.

In the presented studies, HIT showed similar effects compared to HVT achieved in less training time. The data also reveals performance enhancing effects depending on time of recovery. This saving in time may favor training contents such as technical and strength drills as well as recovery in the long term development of performance.

POST-RESISTANCE EXERCISE HEMODYNAMICS IN ELDERLY

QUEIROZ, A.C.C., KANEGUSUKU, H., CHEHUEN, M.R., COSTA, L.A.R., WALLERSTEIN, L.F., MELLO, M.T., UGRINOWITSCH, C., FORJAZ, C.L.M.

UNIVERSITY OF SAO PAULO - FEDERAL UNIVERSITY OF SAO PAULO

Introduction: Aging process reduces muscle mass, strength and power; and resistance training has been recommended to delay this process. It's known that each session of resistance exercise promotes post-exercise hypotension in young subjects. However, aging is accompanied by many cardiovascular alterations that might change hemodynamic responses after exercise. Thus, the purpose of this study was to investigate blood pressure (BP) and its hemodynamic mechanisms after a single bout of resistance training in elderly subjects.

Methods: Sixteen normotensive elderly (63±1 years; 123±2/79±1 mmHg), who were already participating in a strength training program for 12 weeks, underwent two experimental sessions in a random order: Control (C) – remain seated for 90 min, and Exercise (E) – 7 resistance exercises (3 sets of 8 RM). Auscultatory BP, cardiac output (CO-CO2 rebreathing) and heart rate (HR-ECG) were measured before and at 30 and 60 minutes after interventions. The responses (difference between values measured post and pre interventions: Δ30-pre and Δ60-pre) were compared by a 2-way analysis of variance for repeated measures. Data are presented as means±SE.

Results: Systolic and mean BP increased in the C (greatest increases = +8.4±1.4 and +4.4±0.9 mmHg, P<0.05, respectively), and did not change in the E session. Diastolic BP did not change after both sessions. Systemic vascular resistance increased similarly in both sessions, while CO decreased significantly only in the E (greatest decrease = -0.5±0.1 l/min, P<0.05). Stroke volume decreased, while HR increased significantly in the E session (greatest responses = -9.6±1.9 ml/beat and +3.7±1.5 beat/min, P<0.05, respectively).

Conclusion: In trained elderly, each session of resistance training promoted post-exercise hypotensive effects, since BP increased after the C session, which was prevented by the E session. This effect was due to a CO decrease that is not compensated by an increase in systemic vascular resistance. CO reduction after resistance exercise was mediated by a stroke volume decrease that was not compensated besides the HR increase.

CHANGES IN MUSCULAR STRENGTH: FROM BIRTH TO DEATH

SEENE, T., KAASIK, P., PUHKE, R., SEENE, M.

UNIVERSITY OF TARTU

Introduction: It is well known that there are gradual, progressive and regressive changes in body structure and function from birth to death. These progressive changes are rapid during the intensive growth period but slow down from the fourth decade of life, particularly

skeletal muscle mass and strength (Herndon et al., 2002). Protein synthesis in skeletal muscle, particularly contractile protein myosin heavy chain (MyHC), has been found to be a predictor of locomotory function. A reduction of contractile proteins contributes to the decline muscular strength (Seene et al., 2008). The purpose of the present study was to assess changes in muscle strength from one month to 80 years old age, and find the relations with changes in locomotory function through the life-span.

Methods : Under assessment were persons from one month till 80 years of age. Pediatric assessment techniques were used for physical examination during the preschool period. Arm and leg strength (1RM), muscle fiber types, cross-section area, myonuclear domain size and the myosin heavy chain isoform pattern were measured as described earlier (Seene et al., 2008).

Results: Strength development starts at birth in the form of movements in gravitational field. Taking into account that a infant's head is 2/3 of its total mature size and muscle mass comprises about 20% of the total bwt, these movements have to exert a force of attraction. After the fourth decade of life, muscle strength slowly begins to decline. Between 30 and 40 years of age, the decline was ~5%, 40 and 50 ~14%, 50 and 60 ~16%, 60 and 70 ~26%, and 70 and 80 ~30%. The decrease of muscle strength is accompanied with the decrease of FT muscle fibers and IIx isoform relative content of MyHC.

Discussion: It is a widely accepted standpoint that the best time for strength development starts from late puberty. In reality, a newborn infant starts to fight with gravitation at birth and this process is actual strength development. The development of posture control across the life-span and its integration with locomotory function show dependence on the muscle strength. When balancing, older adults as well as like young children, use antagonist muscles more often in coactivation with agonist muscles (Woollacott et al., 1986). Muscle weakness is the main factor in the dysfunction of locomotor acitvity and balance through the life-span. A decline in muscle strength is in good agreement with the decrease of proportion of FT muscle fibers and IIx MyHC isoforms relative content in skeletal muscle. Locomotory dysfunction in infants and elderly people is the result of insufficient muscle strength.

THE EFFECT OF THREE DIFFERENT TRAINING MODALITIES ON MUSCLE STRENGTH, MUSCLE MASS AND FUNCTIONALITY, AMONG ELDERLY

ANDERSEN, V., CUMMING, K., KVAMME, N.H., SOLBERG, P., TOMTEN, S.E., HALLÈN, J., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORTS SCIENCES

Introduction: Muscle strength and muscle mass will decrease with age (Melton, III et al., 2000; Doherty et al., 1993). As a consequence it becomes harder to perform everyday activities (Jette & Branch, 1981). It is well recognised that physical training has the potential to counteract these changes. However, what kind of training that is optimal for both regaining strength and function is still unclear. The aim of this study was therefore to compare the effect of three training modalities on muscle strength, muscle mass and functionality.

Methods: A total of 51 elderly men and women (aged 69-88) were randomly divided into three training groups and one control group (CG). The training groups exercised 3 times pr week for 12 weeks while the CG just continued their normal activity. The training groups were a resistance training group (RTG) following a progressive resistance program consisting of 8 exercises (3 leg exercises) performed with one to three 4-12 RM sets, a functional resistance training group (FTG) training 8 exercises simulating movements in everyday activities (4 leg exercises) performed with one to two 12-15 RM sets and one endurance training group (ETG) which trained Nordic walking, aerobics and walking. All subjects were tested in 1 RM knee-extension, stair climbing without- with 10kg and 20kg external loading, chair raise, counter movement jump, maximal gait velocity and body composition with DEXA.

Results: RTG increased performance in knee-extension (mean±SEM:37±4.5%), stair climbing with 10kg (12±3.4%) and chair raise (9±2.3%). FTG increased performance in knee-extension (29±5.6%), all stair climbing tests (17±2.5%,19±2.1% and 15±2.5%) and chair raise (12±2.8%). ETG increased performance in knee-extension (24±3.5%) and CG increased performance in knee-extension (16±4.4%) and stair climbing with 10kg (8±2.2%) and 20kg (6±2.6%). RTG, FTG and ETG all increased lean body mass (respectively 3±0.8, 2±0.5 and 4±0.8%), but only FTG increased total body mass (0.9±0.2%). RTG increased knee-extension performance more than CG, FTG increased stair climbing performance more than ETG and chair raise performance more than CG. RTG, FTG and ETG increased lean body mass more than CG.

Discussion: In our study we compared three different training modalities and found that all the training groups increased lean body mass and muscle strength. In the tests of functionality only the RTG and FTG increased their performance, especially in the stair climbing tests. Surprisingly the CG also improved their muscle strength and two out of three stair climbing tests. A possible explanation may be that also the CG increased activity level because they participated in the study. In conclusion the RTG and FTG increases muscle mass, muscle strength and functionality in a similar manner.

INFLUENCE OF TRAINING FREQUENCY AND ADVANCING AGE ON THE HISTO-MORPHOLOGY OF ADRENAL MEDULLA IN RATS

VINCENT, S., POULAIN, S., TURLIN, B., LE DOUAIRON-LAHAYE, S., MALARDÉ, L., LEMOINE MOREL, S., CARRÉ, F., ZOUHAL, H.

LABORATOIRE MOUVEMENT SPORT SANTÉ (M2S)

Introduction: Aging induces alterations of sympathoadrenergic system (Zouhal et al. 2008). It could be explained by an increase in the sympathetic nervous activity with advancing age and/or by a compensatory mechanism related to the fall of the organization sensitivity to sympathoadrenal stimulation (Mazzeo et al. 1997). It is well known that endurance training induces an increase in adrenal gland (AG) and adrenal medulla (AM) volume in young rats (Stallknecht et al. 1990). Previous internal study showed that high frequency of endurance training is more efficient in young rat (Poulain et al. 2008). In old rat, the endurance training frequency efficient to modify the volume of AG and AM remained to be clarified. The purpose of the present study was to compare the effects of two endurance training programs with different frequencies (endurance training session per week) on AG and AM in old rats.

Methods

16 old Wistar rats were randomly assigned to one of the three groups: untrained (UT), trained 2 times per week (T2) and trained 5 times per week (T5). Training consisted in 8 weeks of endurance training (1h/day on a treadmill at a speed of 20 m/min up a 10 degrees inclineon). All rats were weighted at the beginning and the end of the protocol. 24h after the last training session, animals were killed and AG were removed, weighted and frozen for subsequent analysis. The method of volume determination is based on the measurement of the elliptical surface of every cut of 10μm thicknesses spaced out by 99 cuts. Formula used was vol (mm3) = Σ each surface x 0,1. The ImageJ software calculates the surface from the number of present pixels. The surface delimitation is determined manually. The results are given as mean ± SD.

Results: T2 (489 ± 46 g) and T5 (495 ± 35 g) had not significantly different of body mass to UT (485 ± 6 g) at the end of the endurance training program. The volume of AG is not significantly different between the three groups. However, T2 and T5 have a lower volume of MS (1.53 ± 0.52 mm3 and 1.88 ± 0.43 mm3, respectively) than UT (2.48 ± 0.36 mm3). Also, AM/AG volume is higher in sedentary rats (0.112 ± 0.008) compared to T2 (0.088 ± 0.020) and T5 (0.089 ± 0.031).

Discussion

Amazingly, in older rat, it seems that two endurance training session per week induce a decrease in AM volume without changing the AG volume. This data shows an opposite effect of endurance training between young and old rats. This could be explained by an initial higher volume of AM in old untrained rat and the endurance training could have a beneficial effect at this level by reducing. So, training seems to give « a second youth » to the older rats at AM area. In conclusion, endurance training one hour per day realized two times per week seems sufficient to induce such adjustments in the AM of older rats.

AGE-SPECIFIC AND TRAINING-INDUCED MUSCLE ACTIVATION PROFILES DURING REPETITIVE HOPPING

HOFFRÉN, M., ISHIKAWA, M., KOMI, P.V.

UNIVERSITY OF JYVÄSKYLÄ

Neural activation strategies play an important role during the dynamic movements by controlling the fascicle behavior and therefore also the fascicle-tendon interaction and movement efficacy. There are indications that the muscle activation profiles (1) and fascicle-tendon interactions (2) are age-specific. This information has been obtained during dynamic movements performed by young and older individuals using the same exercise intensities in absolute scale. This may not be a preferred protocol since activation strategies are modified by the movement intensity (3). The purpose of the present study was to investigate whether the age-specific muscle activation profiles exist in repetitive hopping exercise and whether the hopping training modifies the activation profiles in elderly. The exercise intensities for younger and elderly subjects were adjusted according to their individual maximal hopping performance.

12 elderly and 8 young subjects performed repetitive bilateral hopping with different intensities (50%, 65%, 75%, 90% and maximal) of the maximal vertical ground reaction force. EMG activation of the soleus (SOL), gastrocnemius medialis (GM), gastrocnemius lateralis (GL) and tibialis anterior (TA) muscles were investigated during hopping. RMS values of EMG were calculated for the preactivation (100ms prior to contact), braking and push-off phases. The measurements were repeated for the Elderly after 2 weeks and 12 weeks of hopping training that was performed 3 times per week.

When the ratio preactivation to braking phase activation (pre/brak-ratio) was calculated, Elderly showed signicantly higher values in SOL, GM and TA muscles than Young. The trend for the same was also seen in GL (p=0.053). This ratio did not change in Elderly during hopping training. However, when another EMG ratio (braking to push off) showed originally lower values among Elderly, the specific hopping training increased this ratio especially in high exercise intensities (90% and max hopping) in SOL, GM and GL muscles.

It is likely that age-specific muscle activation profiles exist in repetitive hopping exercise. As compared to Young, Elderly have high preactivation of the agonist muscles, then less activation in the braking phase and increasing activation towards the end of push-off phase. This activation in elderly may affect the stiffness regulation and utilization of tendinous tissue elasticity. However, the activation strategies are trainable also in elderly since the short-term hopping training shifted the activation from the push-off phase towards the braking phase resembling the activation of young individuals.

CARDIORESPIRATORY RESPONSES DURING SIX MINUTES WALKING TESTS IN TRAINED AND UNTRAINED ELDERLY SUBJECTS

YÁZIGI, F., REIS, J., ALVES, F., ARMADA-DA-SILVA, P.

FACULTY OF HUMAN KINETICS

Although several studies used the Six Minutes Walking Test (6MWT) in order to evaluate the functional capacity of special populations, there is a lack of information regarding the cardiorespiratory parameters obtained during this test in healthy elderly subjects, as well as its sensitivity to the effect of exercise training. The purpose of this study is to characterize the cardiorespiratory responses during the 6MWT by comparison of two groups of elderly subjects (trained and untrained). Methods: Twenty eight subjects divided into two groups: trained (T) (n=20; age: 73.1 ± 6.7 yrs (SD); height: 1.61 ± 0.1 m; weight: 68.3 ± 11. kg) and untrained (UT) (n=8; age: 69.0 ± 7.3 yrs (SD); height: 1.60 ± 0.1 m; weight: 73.2 ± 9.0 kg) performed the 6MWT with cardiorespiratory responses assessed by a portable gas analyzer (Cosmed K4b2). Subjects were instructed to walk as fast as possible and the distance (d) and gait speed (v) were recorded. The maximal oxygen uptake (O2) and heart rate (HR) achieved were calculated as the average of the first 3 minutes (O2_3') and the last 3 min of the test (O2_6'). The relation between the HR obtained by each subject and their theorical maximal heart rate according to Tanaka's formula was established (%HR). The training process consisted in 8-months multicomponent training, developed according the ACSM guidelines. Independent and paired T-tests were used to compare means between and within groups, respectively. Pearson's product moment

coefficient was used to correlate variables. Results: Trained group presented higher d (T = 660 ± 83 m; UT = 520 ± 82 m; p = 0.00), v (T= 1.83 ± 0.2 ms-1; UT = 1.44 ± 0.2 ms-1; p = 0.00), O2 (T = 19.9 ± 8.0 ml min-1kg-1; UT = 14.3 ± 4.3 ml min-1kg-1; p = 0.03) and %HR (T = 83 ± 11%; UG= 70 ± 14%; p = 0.01). The difference between O2_6' and O2_3' was 2.6± 2 ml min-1kg-1 in T (p= 0.000) and 0.4± 0.9 ml min-1kg-1 in UT (p= 0.24) also suggesting higher exercise relative intensity in the former group. Also, significant correlations were found between d and O2 (r = 0.68; p = 0.00) and between %HR and O2 (0.67; p = 0.00). The results demonstrate that 6MWT is a valid instrument to assess aerobic capacity in elderly individuals, confirming the higher aerobic performance in trained individuals. The T group increased the oxygen consumption until the end of test either due to increased walking speed or due to higher intensity exercise and occurrence of a slow component of O2 consumption kinetics. No such phenomenon was observed in the UT group.

CORTICOSPINAL EXCITABILITY DURING CONCENTRIC AND ECCENTRIC MAXIMAL VOLUNTARY CONTRACTION

DUCLAY, J., PASQUET, B., KLASS, M., MARTIN, A., DUCHATEAU, J.

UNIVERSITÉ LIBRE DE BRUXELLES

Introduction: During submaximal plantar flexion, it has been reported that the excitability of the spinal and and corticospinal pathway, evaluated respectively by the H-reflex and by motor evoked potentials (MEP) elicited by transcranial magnetic stimulation, was lower during eccentric compared with concentric contraction (Sekiguchi et al., 2003). In a previous study, we showed that the depression of the H-reflex amplitude during eccentric compared with concentric maximal voluntary contractions (MVC) was only observed in the soleus (SOL) muscle while no muscle contraction type effect was obtained for the medial gastrocnemius (MG) H-reflex (Duclay et al., 2008). Our findings suggested that, during eccentric MVC, the neural control mainly act at spinal level (Duclay and Martin 2005). The aim of the current study was therefore to investigate cortical and spinal neural mechanisms involved in the neural modulations observed during eccentric MVC in two muscles (SOL and MG) which could be differently affected by peripheral inhibitory mechanisms.

Methods: Experiments were performed on 9 healthy men. Maximal H-reflexes, M-waves and MEP were evoked in both SOL and MG at an ankle angle of 90° during concentric and eccentric MVC (i.e., Hsup, Msup and MEP, respectively). The MEP / Msup and Hsup / Msup were calculated to investigate the corticospinal and spinal excitability.

Results: During MVC, both SOL Hsup / Msup and MEP /Msup ratios were lower during eccentric contraction (P<0.01) as compared with concentric contraction (0.39 ± 0.04 vs. 0.54 ± 0.04 and 0.13 ± 0.01 vs. 0.17 ± 0.01 respectively) while corresponding MG ratios were not affected by the muscle contraction type (P>0.05). To evaluate the specific neural control at corticospinal and spinal level during eccentric MVC as compared with concentric MVC, differences between concentric and eccentric values of the amplitude for MEP / Msup (ΔMEP) and Hsup/Msup (ΔH) were fitted into linear regression. For the SOL, significant correlation was observed between ΔMEP and ΔH (P<0.05). When ΔH was increased, a decrease of ΔMEP was obtained.

Discussion: The SOL results indicate that the excitability of the corticospinal pathway is reduced during eccentric compared with concentric MVC. The relation between ΔMEP and ΔH, observed for the SOL, suggest that, during eccentric MVC, cortical excitability was increased in order to compensate for spinal inhibition. Despite this increase, the MEP / Msup ratio was lower during eccentric MVC, suggesting that the corticospinal pathway seems to be mainly modulated at spinal level. In the same way, when the amount of inhibition was less at spinal level (i.e. MG's data) (Duclay et al 2008), the corticospinal excitability was similar during eccentric compared with concentric MVC.

ELITE CROSS-COUNTRY SKIERS' ADAPTATIONS OF THE DIAGONAL STRIDE TECHNIQUE AT DIFFERENT INCLINATIONS

GOEPFERT, C., HOLMBERG, H.C.,4, MUELLER, E., LINDINGER, ST.,2

UNIVERSITY OF SALZBURG, AUSTRIA

3. Swedish Winter Sports Centre, Department of Health Sciences, Mid Sweden University, Östersund

4. Swedish Olympic Committee, Stockholm, Sweden

Introduction: Despite the equal relevance of classic and freestyle in modern cross-country skiing, the main focus of biomechanical studies has mainly been on the latter technique. Diagonal stride [DIA] as a main classical technique has further developed over the last 20 years. There is still a lack of biomechanical data describing DIA and adaptations to different inclinations. A previous study showed that skiers increased cycle rate rather than cycle length as the strategy to adapt to increasing inclinations (Bilodeau et al. 1992). However, no kinetic or joint kinematic data were presented. The aim of the present study was to identify kinetic and kinematic adaptations in DIA at different inclinations.

Methods: Twelve elite XC skiers (Swedish National Team; VO2max-DIA: 72.3 ± 3.8 ml·kg-1·min-1) performed DIA roller skiing at treadmill inclinations of 3°, 6° and 9° at 11 km·h-1 for biomechanical analyses. Leg and arm joint angles (goniometers), pole force (strain gauge), both at 2000 Hz, and plantar force (Pedar Mobile) at 100 Hz were recorded. Repeated measures ANOVA were calculated in order to examine the biomechanical differences between the named inclinations. The statistical level of significance was set at P<0.05.

Results: Cycle time [CT] (P<0.01) and relative (%CT) arm recovery time (P<0.05) decreased at higher inclinations. Cycle rate and relative poling time both increased (both P<0.01). No differences were found for the relative durations of leg-ground contact and leg swing. All the force values measured were greatest at the steepest inclination, including peak pole and leg forces, forefoot force in ground position and impulses of pole and leg push-off (all P<0.01). Elbow [EA], hip [HA] and knee [KA] angle minima, EA at pole plant, KA at ski plant and HA maximum before push-off decreased (all P<0.01). The elbow extension range of motion [ROM] and knee (both P<0.01), as well as hip

push-off extension ROM (P<0.05), increased with inclination. Angular push-off flexion velocity (P<0.01) decreased, along with higher angular push-off extension velocities in the ankle (P<0.05), knee and hip joints (both P<0.01) at steeper inclinations.

Conclusion: Elite skiers adapt the DIA technique to increased inclinations through substantial changes in pole and leg kinetics and joint kinematics, with only minor changes in specific phase durations. Arm and leg actions show larger amplitudes, higher angular velocities, longer poling times, higher forces and impulses generated at higher frequencies. We suggest that XC skiers should use technique, endurance and strength training at different inclinations in order to train these aspects specifically.

KNEE JOINT LOADING DURING LEVEL WALKING WITH MBT SHOES IN OVERWEIGHT MEN

BUCHECKER, M., WAGNER, H., PFUSTERSCHMIED, J., MÜLLER, E.

UNIVERSITY OF SALZBURG

Felson (1996) identified obesity and overweight as main risk factors for the onset of knee osteoarthritis (OA). According to Gushue et al. (2005) high body mass initiates primarily greater dynamic loads on the medial joint compartment as assessed by a higher peak external knee adduction moment during walking. Furthermore DeVita & Hortobágyi (2003) stated reduced knee flexion excursion in healthy obese adults, which indicates not only 'quadriceps avoidance' but also higher co-activation between antagonistic muscle pairs (Childs et al. 2004). The aim of the present study was to determine whether an MBT shoe alters walking kinetics and muscle coordination in overweight men with regard to knee OA prevention.

Ten healthy overweight men (32.0±7.9 yr, 179.2±5.8 cm, 91.3±7.0 kg, 28.4±1.8 kg/m2), familiar with MBT, participated. Subjects were instructed to walk 6 trails with their own and MBT shoes at their preferred speed (±0.2 km/h), which was controlled by a wireless Brower timing system. Kinetics and kinematics were obtained simultaneously with an AMTI force platform (2000 Hz) and a Vicon MX13-system consisting of eight cameras (250 Hz). Surface EMG activities of 6 right-leg muscles were recorded with a 16 channels Biovision measurement system (2000 Hz). Data were synchronised by an external trigger signal and processed by Nexus 1.2 (Oxford Metrics) and IkeMaster 2004 (Ike Software Solutions). Paired sample t-test and Cohen's effect size dz were used to compare peaks of 3D external knee net joint moments, IEMG of vastus lateralis (VL), rectus femoris (RF) and biceps femoris (BF) as well as average VL/BF co-activation during stance phase.

No relevant differences in average VL/BF co-activation (t(9) = -.54, p = .60, dz = .17), muscle intensities (IEMG) of VL (t(9) = -.41, p = .69, dz = .13), RF (t(9) = -.01, p = .99, dz = .00) and BF (t(9) = .39, p = .71, dz = .12) were observed between the control and MBT situation. Similar results could be obtained for peak knee flexion moment (t(9) = .58, p = .58, dz = .18) and peak knee external rotation moment (t(9) = -.78, p = .46, dz = .25). However, concerning peak knee adduction moment strong significant effects were found. In comparison to the control shoes this variable demonstrated an average reduction of 10% (t(9) = 2.64, p = .03, dz = .83) for the MBT condition.

First data exhibit decreased knee joint loads using MBT. In fact, this shoe seems to be advantageous for knee OA prevention in overweight men. Further kinematic and kinetic analysis is warranted to find biomechanical reasons for the smaller adduction moment. Due to its construction and referring to Kälin & Segesser (2004) a lateral shifting of the centre of pressure and thus a reduced frontal knee moment arm are presumed as main factors for this result.

RELATIONSHIP OF REARFOOT MOTION TO VERTICAL AND LEG STIFFNESS IN RUNNING

ELTARVÅG, B., ERIKSRUD, O., SMITH, G.

NORWEGIAN SCHOOL OF SPORT SCIENCES

During running, the lower extremities function much like a mass-spring system. Near the middle of stance, the leg spring is maximally compressed. This is approximately the time of maximal pronation, commonly described by rearfoot eversion. Few studies have explored the relationship between rearfoot motion and leg stiffness (Viale, 1998). The current study which focuses on foot motion was part of a larger project evaluating the influence of lower extremity joint kinematics on leg and vertical stiffness.

Methods: 15 female subjects were all tested while running over a 20 m lab runway at a target speed of 3.8 m·s-1. Three dimensional kinematic data were obtained from reflective markers on the lower extremity using a Pro-Reflex motion capture system (Qualisys AB, Sweden). Three-dimensional kinetic data were measured using three floor mounted force plates (AMTI, USA) in sequence placed midway in the runway. Three or more successful trials within a 5% range of 3.8 m·s-1 were analyzed using MatLab and Visual3D. Vertical and leg stiffness were calculated based on the method by McMahon and Cheng (1990). Rearfoot angle was calculated from tracking markers in Visual3D as the relative angle between the foot and shank segments with 0° taken as the positioning in a static, standing trial. Maximum rearfoot eversion (EvMax) along with eversion range of motion (EvROM: angular change from heelstrike to EvMax) were determined. The relationships of EvMax and EvROM to vertical and leg stiffness were evaluated using Pearson's product moment correlation (r).

Results: Mean EvROM during early stance of running was 14.4 ± 4.2° while EvMax was 11.5 ± 2.7°. Vertical stiffness for the runners was 31.8 ± 4.7 kN·m-1 while leg stiffness averaged 10.3 ± 1.5 kN·m-1. EvRom and EvMax were not significantly correlated with neither vertical nor leg stiffness.

Discussion: The mass-spring model applies to the whole running leg as a system which collectively exhibits elastic properties. The model does not attempt to identify which anatomical structures produce these characteristics. However, it is likely that structures surrounding ankle, knee and hip all contribute in some amount to this response. Foot kinematics during stance may help to absorb shock during impact with the ground, but in addition, foot motion provides a mechanism for partially explaining the elastic characteristics of the running leg. EvROM was not found to be significantly related to leg stiffness. This is only one plane of a complex foot motion and only one of several joints which could contribute to leg stiffness. Further analysis of the ankle and foot in other planes of motion as well as other joints needs to be analyzed to better understand this important fraction of leg mechanics.

CHANGES IN MOTOR UNIT CHARACTERISTICS AFTER ECCENTRIC ELBOW FLEXOR EXERCISE

PIITULAINEN, H., HOLOBAR, A.,3, AVELA, J.

1. UNIVERSITY OF JYVÄSKYLÄ, 2. POLITECNICO DI TORINO, 3. UNIVERSITY OF MARIBOR

Introduction: Morphological evidence suggests that predominantly fast-twitch fibers are prone to sarcolemmal disruption during eccentric exercise (Jones et al., 1986). However, it is unclear if the function of motor units (MUs) is selectively affected.

Methods: High-density surface electromyographs (sEMG) were recorded with 5×13 electrode array (LISiN-OT Bioelettronica, Torino, Italy, inter-electrode distance of 8 mm) and decomposed with Convolution Kernel Compensation approach (Holobar and Zazula, 2004) to examine MU characteristics in m. biceps brachii after eccentric elbow flexor exercise (50 repetitions, 20 s intervals). Nine healthy subjects were measured at wide range of isometric contraction levels: 10%, 20%, 30%, 40% 50% and 75% of maximal voluntary contraction (MVC) before (BEF) the exercise, and two hours (2H), two days (2D) and four days (4D) post-exercise. Number of extracted MUs per session was: BEF: 471 MUs, 2H: 228 MUs, 2D: 426 MUs and 4D: 470 MUs. The following MU characteristics were extracted for each identified MU: mean instantaneous discharge rate (IDR), mean muscle fiber conduction velocity (CV) (McGill and Dorfman, 1984), and mean power frequency (MNF).

Results: As a result of the exercise, MVC force decreased by 21.3 ± 5.6 % 2H ($p < 0.001$) and by 12.6 ± 11.1 % 2D ($p < 0.01$) post-exercise. 2H after the exercise, IDR increased from 19.5 ± 4.4 pps (BEF) to 22.6 ± 5.0 pps and from 24.5 ± 5.6 pps (BEF) to 28.3 ± 3.0 pps in 50% ($p < 0.01$) and 75% ($p<0.05$) of MVC contraction, respectively. When IDR was plotted against the absolute force level, the regression slope was significantly steeper at 2H than BEF, suggesting increase in the rate coding of MUs. In contracts to IDR, a reduction in CV was observed in 40% (from 4.4 ± 0.3 m/s to 4.2 ± 0.3 m/s, $p < 0.05$), 50% (from 4.5 ± 0.3 m/s to 4.2 ± 0.3 m/s, $p < 0.01$) and 75% (from 4.4 ± 0.3 m/s to 4.2 ± 0.3 m/s, $p < 0.01$) of MVC contraction levels at 2H (BEF vs. 2H). MNF showed reduction only in 75% of MVC contraction (from 102.0 ± 18.6 Hz (BEF) to 91.1 ± 20.4 Hz (2H), $p < 0.05$). When CV and MNF were plotted against absolute force level, the steepness of both regression slopes was significantly reduced at 2H with respect to BEF, implying possible impairment in sarcolemmal conduction. No changes were observed in these variables when the experiment was repeated without the exercise in seven control subjects.

Discussion: Based on Henneman's size principle, the present results suggest that intensive exercise can selectively disturb the function of high-threshold MUs. These impairments seem to be related to slowing of sarcolemmal action potential conduction and presumably force production of the affected MUs. Thus, the increased rate coding of active MUs seems to be an attempt to compensate this force reduction.

THE RELEVANCE OF SUBTALAR-JOINT-ANATOMY ON THE INCIDENCE OF CHRONIC OVERUSE INJURIES IN THE LOWER LIMBS.

REULE, C.A., ALT, W.W.

UNIVERSITY OF STUTTGART

Introduction: Chronic overuse injuries (COI), frequent in the Achilles tendon, are of major importance to athletes, especially high performance athletes. Little is known about the predisposing factors of these injuries. Therefore, the aim of this study is to identify the relationship between individual anatomical factors of the subtalar-joint and COI through the use of a measurement system for determination the spatial orientation of the subtalar-joint-axis (SJA) and a treadmill-analysis.

Methods: An ultrasonic pulse-echo based measurement system (Zebris®) determined the spatial orientation of SJA in-vivo and in real-time. The arch-index and the angle of gait were also determined by a treadmill that enables plantar pressure measurement (Zebris®). Video-analysis allowed for investigation of the rolling motion of the foot during walking. Information about previous injuries and running performance was collected with a questionnaire. Measurements were taken from 495 subjects, mainly consisting of long distance runners with a running distance of at least 25 km per week and a running history of 3 years. Data from 307 subjects was included.

Results: Of 307 subjects, 69% had previously been injured. A total of 664 injuries were counted. 22% of these injuries were located at the ankle, 21% at the knee and 14 % at the Achilles tendon. By means of the Arch-index, it was found that 42% of subjects with Achilles tendon problems also had high arches. In subjects without Achilles tendon problems, only 34% had high arches. The average of the inclination angles of 614 SJA was 42° ± 16° and the average deviation angle (DA) was 11° ± 23°. There was a significant difference ($p= 0.002$) between the mean DA of people with Achilles tendon problems (18° ± 23°) and people without (10° ± 23).

Conclusion: The injury-rate in this study was 69% higher than that stated by Mayer (1999). The Results of Arch-index analysis confirmed the conclusion by Lohrer (2006), that a high arch is a common cause for Achilles tendon injuries. The mean inclination angle of the SJA found in this study approximates the results of Isman (1969). In contrast, the mean DA measured in vivo was smaller and the SJA was closer to the foot bisection than measured by Isman (1969). However, the DA (18°) of subjects with Achilles tendon problems was higher than recorded by Isman (1969). Based on these results, long distance runners with higher DA are at a higher risk to suffer from Achilles tendon problems.

PS-PL01 Born to move? Perspectives from evolutionary biology and the social sciences

HUMAN ADAPTABILITY TO MOVE: INTERNAL AND EXTERNAL RESOURCES.

MINETTI, A.E.

UNIVERSITY OF MILAN

Differently from other species that, apart from long migrating animals, are optimized in their body design to move within a given habitat, humans have always struggled to adapt to all sorts of environments, ranging from level to steep terrain, at all latitudes, in a variety of climates, even on different planets. Also, within the same environment and penalized by the bipedal, erect posture, man has always tried to push the muscle powered locomotor performance to the limit, by inventing tools capable to better exploit the same engine and machinery. Achieving a higher speed at a manageable metabolic cost and expenditure promoted the development of paved roads, optimally steep paths, prepared snow surfaces, calm (sometimes frozen) water ways, and a variety of locomotion aids like carts and bicycles, skis/skates and sleds, canoes and rowing boats, up to human powered submarines and aircrafts.

By reviewing the history of an often fortuitous 'symbiosis' of physiology and engineering in the different forms of locomotion (see References below), some of which dates back to prehistory, the invariant characteristics of the propeller (muscle) emerge and the most frequent winner, i.e. the pedalling paradigm, is the modality of choice in many forms of modern propulsion.

BORN TO MOVE? PERSPECTIVES FROM THE SOCIAL SCIENCES.

FASTING, K.

NORWEGIAN UNIVERSITY OF SPORT

Human beings not only are born to move but also have the right to move. UNESCO'S International Charter of Physical Education and Sport, (Article 1) states that: "The practice of physical education and sport is a fundamental right for all". In spite of the fact that people are born to move and have the right to do so, it often doesn't seem to be put into practice. As a result people's participation in leisure time physical activities and sport varies between and within cultures particularly in relation to gender, but also in relation to religion, sexuality, social class, disability, race, ethnicity and immigrant status. A further perspective from the social sciences on this issue will therefore be to discuss and explain this variation. Due to the time available the focus of the presentation will mainly be on the relationship between gender and sport in a social constructionist perspective, with a focus on 'doing gender'. Gender refers to cultural meanings and connections associated with one's biological sex, and what is appropriate behaviour for women and men (Lorber 1994). Historically there has been a strong relationship between sport and hegemonic "masculinity", while the opposite has been true for sport and "femininity". The societal gender stereotypes have therefore functioned as barriers for many girls and women. This has led to gender based discrimination in sport (United Nations 2007). Many of these barriers have been overcome over the last few years since both sport and the concepts of "masculinity" and "femininity" are constantly changing. The presentation will close with some examples of how people have met the challenges they have faced through sport, how they have overcome discrimination, and how involvement in sport has challenged the gender stereotypes and discrimination, and how involvement in sport can be a vehicle for gender equality and empowerment.

IS-NU01 Nutrition and training adaptations (GSK Symposium)

THE EFFECT OF NUTRITION ON THE ADAPTATION TO TRAINING

MILLER, B.

COLORADO STATE UNIVERSITY

Exercise training initiates a series of signals that permit the remodeling of cells to be better equipped to deal with that stimulus in the future. To optimally adapt to the signals put in motion, amino acid building blocks must be provided to construct the proteins of interest. Post-exercise protein provision is well documented to increase protein synthesis after a bout of resistance training. Less explored is the effect of post-exercise protein on endurance training adaptation. However, it is important to recognize that post-exercise protein intake might be just as important for endurance-specific adaptation. In this talk, the importance of post-exercise protein ingestion will be discussed in the context of strength and endurance training. Further, gaps in current research will be identified to optimize training adaptations.

DO ANTIOXIDANTS ENHANCE OR SUPPRESS TRAINING INDUCED ADAPTATIONS?

PHILP, A.

UNIVERSITY OF DUNDEE

Exercise involves a complex series of cellular events, which combine to mediate skeletal muscle adaptation. Muscle contraction evokes signal transduction pathways regulated by calcium and ATP fluctuations as well as a stress response leading to systemic release of hormones, and the muscle specific generation of reactive oxygen species and cytokines. As a general process, this response can be termed exercise specific inflammation and recent research suggests that this transient inflammatory response is a key factor in exercise adaptation (Petersen and Pedersen, 2005). If inflammation is prolonged however, such as during repetitive periods of intense training, or sustained exhaustive exercise, deleterious effects develop within the working muscle suggesting that the range over which inflammation is beneficial is small. Radicals and reactive oxygen species (ROS) are molecules that initiate damaging oxidation reactions within the cell (Powers et al., 2004). ROS generation has been linked with exercise induced oxidative injury and muscle fatigue due to an imbalance between oxidant production and the antioxidant capacity of the cell (Powers and Jackson, 2008). There are a number of enzymatic and non-enzymatic defence systems, or antioxidants, in mammalian skeletal muscle which reduce free radicals and reactive oxygen species production. Importantly, dietary antioxidants work in synergy with these endogenous antioxidants to offset ROS induced oxidative stress. With this in mind, recreational and elite athletes supplement with antioxidant agents, in the belief that they will protect the athlete against exercise-induced damage, local inflammation and enhance post exercise recovery. However, recent research suggests that dietary antioxidants may in fact suppress ROS mediated signalling essential for exercise-induced adaptation (Powers and Jackson, 2008). Specifically it appears that ROS generation is important for kinase activity of the AMP-dependent kinase (AMPK), the mitogen activated protein kinases (p38 and p42/44) and their downstream targets NF-κB and the transcriptional co-activator PGC-1α (Gomez-Cabrera et al., 2005; Irrcher et al., 2009). Therefore, whether antioxidants enhance or interfere with training adaptation and whether training regimes and nutritional interventions should be adjusted to account for ROS action in response to exercise remains a controversial issue.

THE DECLINE OF VO2MAX FROM 20 TO 84, THE HEALTH SURVEY OF NORD-TRØNDELAG

ASPENES, S., ULRIK, W.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

Introduction: Maximal oxygen uptake (VO2max) declines with increasing age in both men and women. In cross-sectional studies the decrease has been found to range between 0.40-0.50 mL∙kg-1∙min-1∙year-1 in men and 0.20-0.35 mL∙kg-1∙min-1∙year-1 in women (Jackson et al., 1995). However, most studies use the term VO2peak thereby indicating a submaximal measurement of oxygen uptake, or estimate aerobic capacity from an indirect measurement. We aim to investigate the decline of true VO2max in a large population from measurements on treadmill.

Methods: As a part of the third part of the Health Survey of Nord-Trøndelag (HUNT3), 5641 healthy individuals between 20 and 93 was recruited for testing maximal oxygen uptake. From these, 4060 individuals (2017 women and 2043 men, age 20 to 84) tested their maximal oxygen uptake and during this test reached a respiratory quotient of 1.05 or more. The test was performed with the MetaMax2 and it was brought out with an individualized protocol.

Normality was investigated by Q-Q-plot and histogram with normal distribution curve, and the regression of the relationship between VO2max as dependent variable and age as the independent variable.

Results: VO2max declined from 54.3 ± 8.4 mL∙kg-1∙min-1 in the agegroup 20-29 years to 35.5 ± 6.8 mL∙kg-1∙min-1 in the agegroup above 70 years in men and from 43.0 ± 7.6 mL∙kg-1∙min-1 in the agegroup 20-29 years to 27.9 ± 5.1 mL∙kg-1∙min-1 in the agegroup above 70 years in women. The slope of regression was -0.379 with an R squared of 0.308 in men, and the slope was -0.309 with an R squared of 0.288 in women. The regression was highly significant ($p < 0.001$) for both men and women. The decline in percent per decade is 9.6, 4.3, 10.1, 8.3 and 11.2 in men and 7.0, 4.8, 11.1, 9.2 and 12.4 in women.

Discussion: The decline of 0.379 mL∙kg-1∙min-1∙year-1 in men was slightly lower than earlier reports while the decline of 0.309 mL∙kg-1∙min-1∙year-1 in women was similar to earlier findings. The highly significant p-value of the regression underlines the strength of the relationship while the low R squared indicate that age explains only 30.8% and 28.8% of the decline in men and women, respectively.

The decline is not a steady one, comparing percents decline between decades suggest a decline of shifting steepness. A likely explanation for these shifts is different patterns of physical activity. Unfortunately this was not studied this time in our study. We find that in a healthy Norwegian population, the natural decline from age 20 will be approximately 0.7% per year in both men and women, but the steepness of decline is shifting between the decades and the relationship between VO2max and physical activity should be investigated further in our population.

LONGITUDINAL PREVENTIVE-SCREENING CUTOFFS FOR METABOLIC SYNDROME IN ADOLESCENTS

BOUZIOTAS, C., FLOURIS, A.D., CHRISTODOULOS, A.D., KOUTEDAKIS, Y.

UNIVERSITY OF WOLVERHAMPTON

Introduction: The metabolic syndrome is highly prevalent within adults (Ford & Li 2008; Hu et al. 2004), whereas the coexistence of its components becomes increasingly apparent in young populations (Steinberger & Daniels 2003), suggesting that the syndrome has its roots early in life (Katzmarzyk et al. 2001). Therefore, it is necessary to introduce strong prevention strategies and comprehensive screening in childhood and adolescence. The aim of the present study was to generate longitudinal preventive-screening cut-offs for the metabolic syndrome in adolescents by detecting demarcation points in key and easy to monitor parameters that enable – as early as five years in advance – the successful detection of metabolic syndrome that develops at the age of 17 years (MS17). The variables of interest covered MS risk factors as well as fitness, habitual physical activity, and dietary elements.

Methods: The present study adopted a 6-year design incorporating 4 data collection time points (TPs). Volunteers were assessed prospectively at the ages of 12, 13, 14 and 17. A total of 210, 204, 198 and 187 schoolchildren volunteered at the first (TP1=12 years old), second (TP2=13 years old), third (TP3=14 years old) and fourth (TP4=17 years old), data collection TP, respectively. At each data collection TP, anthropometrical, biological and lifestyle data were obtained. Identical protocols were used for each assessment conducted by the same trained investigators. MS was defined using criteria analogous to the Adult Treatment Panel III definition (Alberti et al. 2006; De Ferranti et al. 2004).

Results: 12% of the participants were diagnosed with MS17, the majority of them being boys (16% vs. 7%, $p<0.033$). The prevalence of the syndrome increased directly with the degree of obesity. Using body mass index (BMI), adiposity and/or aerobic fitness levels in both genders, MS17 could be correctly diagnosed as early as TP1. No such cutoff points were found for high-density lipoprotein cholesterol, triglycerides, blood pressure and fasting plasma glucose levels.

Discussion/Conclusion

With respect to the data presented, it has been established that the calculated longitudinal preventive-screening cutoffs allow successful diagnosis of metabolic syndrome in adolescents using BMI, adiposity or aerobic fitness levels in both sexes. Adoption of such pediatric guidelines may help mitigate future increase in the prevalence of metabolic syndrome.

BIO-PSYCHO-SOCIAL CORRELATES OF PHYSICAL FITNESS IN CHILDHOOD AND ADOLESCENCE

WAGNER, M.O., JEKAUC, D., SCHOTT, N., WORTH, A., BÖS, K.

1. UNIVERSITY OF KARLSRUHE, 2. UNIVERSITY OF EDUCATION SCHWÄBISCH GMÜND, 3. UNIVERSITY OF KONSTANZ, 4. LIVERPOOL HOPE UNIVERSITY

Introduction: Although children and youth currently form the most active segments of the population in the westernized world, there is a marked trend towards an increase in sedentary lifestyle and a decrease in physical fitness among school-age children. In order to counteract the suspected degradation, potential determinants must be known. Previous studies are based on non-representative samples mostly and are only conditionally comparable. Therefore, reliable findings on the determinants of physical fitness are not available. The purpose of the study is the identification of correlates of physical fitness in childhood and adolescence. It is assumed that physical fitness is associated with intrapersonal, behavioural and ecological factors.

Method: Data were obtained from the "Luxembourg project", a representative sample of the 9, 14- and 18-year-old boys and girls from Luxembourg (N = 1188). Physical fitness was measured on the basis of ten motor description categories such as aerobic endurance and flexibility by using a standardised test profile. Intrapersonal (e.g. BMI, sports interest), behavioural (e.g. extent of physical activity; p.a.) and ecological (e.g. peer-group behaviour, socio-economic status; ses) factors were assessed by using a standardised questionnaire (cf. Bös et al., 2006).

Results: Ten multiple regression equations with sequential entry of the model levels help to confirm the suspected relation for eight out of ten motor description categories. Percentage of declared total variance is between 8.0% (fine motor abilities on precision tasks; F=5.19; p=.000; adjusted R^2=.080) and 58.1% (speed of force development in lower extremities; F=67.70; p=.000; adjusted R^2=.581). The identified effects and their directions can be clarified by the example of gross motor abilities under time pressure (F=35.98; p=.000; adjusted R^2=.241). The performance in jumping sideways rises with increasing age (Beta=.64; T=17.52; p=.000), sports interest (Beta=.12; T=4.19; p=.000) and ses (Beta=.10; T=3.51; p=.000) as well as under the influence of an increased extent of p.a. in sports club (Beta=.15; T=5,10; p=.000), whereas lower performances become obvious with increasing BMI (Beta=-.12; T=-3.95; p=.000).

Perspectives

The results delimit the spectrum of potential correlates of physical fitness. However, the related design does not permit any causal conclusions. To receive reliable statements about the determinants of motor development in childhood and adolescence, the individuals included here will be examined prospectively in the context of a longitudinal section study.

EFFECT OF RAMADAN FASTING ON PLASMA LEPTIN AND ADIPONECTIN CONCENTRATIONS AND BODY COMPOSITION IN TRAINED YOUNG MEN

BOUHLEL, E., DENGUEZLI, M., ZAOUALI, M., TABKA, Z., SHEPHARD, R.J.

FACULTY OF MEDICINE OF SOUSSE, TUNISIA

Purpose: To evaluate the effect of Ramadan fasting on parameters of insulin resistance in trained athletes at rest and after aerobic exercise. Methods: Nine male rugby players (age 19 ± 2 yr, height 1.78 ± 0.74 m) were tested three times: one week before observance of Ramadan (C), at the end of the first week (R1), and during the fourth week (R2). They performed a progressive cycle ergometer test at each visit. Data collected at rest and at the end of aerobic exercise included simple anthropometry (body mass, BMI, body fat, fat free mass), biochemical parameters (serum glucose, cholesterol, HDL-cholesterol, triglycerides, creatinine, and serum proteins) and selected hormone concentrations (plasma insulin, leptin and adiponectin) Results: Ramadan fasting was associated with a reduction of body mass and body fat (R2 vs. C, $p<0.01$) without significant change in leptin or adiponectin levels. Conclusion: Lipolysis may have occurred because of increased plasma triglycerides and HDL-cholesterol concentrations.

THE ASSOCIATION BETWEEN CYCLING TO SCHOOL AND BEING OVERWEIGHT IN ROTTERDAM (THE NETHERLANDS) AND KRISTIANSAND (NORWAY)

BERE, E., SEILER, S., OENEMA, A., BRUG, J.

UNIVERSITY OF AGDER

Introduction: Internationally, the prevalence of overweight and obesity is rising. At the same time rates of active commuting are declining. Those who cycle to school have been reported to be more physically fit than those walking or travelling by motorized transport (Andersen et al., in press; Cooper et al., 2006). However, no clear association between weight status and cycling to school has been reported. The purpose of the present study was therefore to assess the potential association between cycling to school and weight status in two cities in where active commuting to school still is common - Rotterdam (the Netherlands) and Kristiansand (Norway).

Methods : Data from the projects ENDORSE (Rotterdam) and YOUTH IN BALANCE (Kristiansand) are used. A total of 16 and 12 secondary schools participated in the surveys, including 1361 and 1197 participants, respectively. Survey years (2004-2006) and age group (12-15 years) were comparable. Commuting to school was self-reported in questionnaires in both studies. The participants were categorised into main mode of commuting. Pupils categorised as cyclist were compared to non-cyclists (walkers, car commuters, public transportation commuters and those not categorised into mode of commuting due to inconsistent reporting). Weight and height were measured by project staff, and overweight was calculated according to sex and age specific international cut-off values for body mass index. Distance from home to school was calculated from postal codes in Rotterdam, but were self reported in Kristiansand. Sex and ethnicity (dichotomized into native Dutch/Norwegian and not native) were self reported.

Results: A total of 35 and 31%, respectively in Rotterdam and Kristiansand, were categorised as cyclists. Bivariately, fewer cyclists were overweight than non-cyclists both in Rotterdam (18 vs. 28%; 95%CI were 14-22% and 25-32%) and Kristiansand (12 vs. 21%; 95%CI were

8-16% and 18-24%). When adjusting for distance to school, sex and ethnicity, cyclists were still less likely to be overweight than non-cyclists both in Rotterdam (OR=0.59; 95%CI were 0.42-0.82) and Kristiansand (OR=0.53; 95%CI were 0.36-0.79).

Discussion: In Rotterdam and Kristiansand cyclists were less frequently overweight than those not cycling to school. However, longitudinal studies are needed in order to assess the aetiology: Are cyclists leaner because they cycle to school, or do adolescents cycle more often because they are leaner (and more fit)?

A 1-HOUR BOUT OF MODERATE-INTENSITY EXERCISE LEADS TO A CLINICALLY SIGNIFICANT REDUCTION IN BLOOD PRESSURE DURING SUBSEQUENT NIGHT-WORK, IRRESPECTIVE OF MEAL SCHEDULE

FULLICK, S., MORRIS, C., JONES, H., ATKINSON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: About 15-20% of European workers are involved in shiftwork, which is a significant risk factor for heart disease and hypertension (Atkinson et al., 2008). Previous research indicates that the blood pressure (BP) of diurnally-active people is reduced for several hours after exercise (Jones et al., 2008). However, no researcher has explored whether post-exercise hypotension occurs when participants are active and eating at night, which is the case for shift-workers. Thus, our aims were to (i) examine the acute effects of evening exercise on BP monitored throughout a subsequent night-shift, (ii) explore whether such effects are moderated by meal frequency, and (iii) examine the relation between exercise-mediated changes in BP and core body temperature (Tc). The primary hypothesis was that exercise reduces BP throughout subsequent night-work.

Methods: Nine participants, aged 20-42 y, completed at least two crossover trials beginning at 18:00 h. Between 19:00-20:00 h, participants either rested or exercised at 50% VO2peak and then remained awake throughout the night, completing various tasks until 05:15 h. Six participants completed a total of four trials in which they exercised or rested while either one meal (60 kJ.kg-1 body mass) was eaten at 22:00 h or two smaller meals (30 kJ.kg-1 body mass) were eaten at 22:00 and 02:00 h. Systolic and diastolic BP, mean arterial pressure (MAP) and heart rate (HR) were recorded every 30 min. Wrist activity and intestinal temperature were also recorded throughout each trial with an accelerometer and a thermometric pill, respectively. Data were analysed with two-factor (trial x time) repeated measures linear mixed models and described as mean (SD).

Results: Following exercise, BP was significantly ($P<0.0005$) lower throughout the night-shift compared with no prior exercise (95% confidence limits for reduction in MAP: 4 to 7 mmHg). The post-exercise reductions in systolic BP and MAP were not moderated by meal frequency, but the reduction in diastolic BP was 6 (2) mmHg when only one larger meal was eaten compared to the reduction of 3 (2) mmHg when two smaller meals were eaten ($P<0.0005$). Like BP, Tc was lower following exercise ($P=0.008$), even though wrist activity and HR were significantly higher following exercise ($P<0.0005$).

Discussion: These novel data clearly indicate that prior exercise lowers BP throughout a subsequent 8-hour night-shift, irrespective of meal schedule. An unexpected finding was that prior exercise mediated a larger reduction in Tc during the night. From a health perspective, our data indicate that regular low-intensity exercise has the potential to attenuate the longer-term increase in blood pressure in this unique population.

MASCULINE MEN PLAYING A WOMAN'S SPORT? MEDIATED REPRESENTATIONS OF MALE HANDBALLERS IN A NORWEGIAN CONTEXT.

BROCH, T., FASTING, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: No matter how rough and physically demanding the game of handball is; unlike many other European countries, the common Norwegian perception of handball defines it as a woman's sport (Lippe, 2001). This is very much due to their huge international successes and the extensive and positive media coverage. When Norwegian handball is constituted as a women's sport, how are Norwegian male handballers portrayed by the media? By the means of a discourse analytic approach; this paper seeks to uncover symbolic gendered meanings in the Norwegian media's (Tv2) portrayal of men's handball.

Methods: The data was collected by recording 5 games from the 2007 World Championship for men and 5 games from the 2008 European Championship for men. The play-by-play commentators were the same two men for all games recorded and their presentation of the games was transcribed and explored by means of a discourse analysis. Phillips & Jørgensen (1999) argues that communication/discourse is structured and patterned. This paper utilizes a discourse analytic approach focusing on gendered structures and patterns.

Results: The analysis uncovered that the play-by-play commentators' discursive representations of Norwegian men's handball was producing images of Warrior Athletes and elevating this particular form of masculine construction. By the use of analogue references to popular culture at large (intertextuality), applying gendered stereotypes, masculine rhetoric, and warlike metaphors; the athletes' bodies where fuelled and armoured with masculine symbols.

Discussion: The media's portrayal of women's and men's handball does not mirror the sport, our world, social relations or identities in a neutral manner (Phillips & Jørgensen, 1999). Viewer ratings and commercial interests, gendered structures and norms shape the mediated (re)productions of sport events (Rowe, 2004). Mediated depictions of male athletes doing power and performance sports commonly use intertextuality, warlike metaphors and gendered stereotypes (Dahlén, 2008). Although Norwegian handball is constituted as a women's sport, Norwegian mediations of male handball follows the general patterns reifying masculine stereotypes within the media-sport-complex. Media depictions of the Handball Warrior link "fictional" masculine symbolism (resonating among its gendered viewers) to the bodily performances on the field, hence cementing gendered stereotypes as embodied identities. The mediation defines handball as a sport for, not only men, but men with a Warrior attitude.

2Norwegian School of Sport Sciences, Department of Physical Education, Oslo, Norway

Introduction: Male gender research shows that for many males, type of work and inherent work culture are central components for personal identity (Morgan 1992). Another important theme in this field of research is the new ideal perception of a more domestically present father (Brandth & Kvande 2003). The purpose of this study was to acquire insight into how young, male outdoor guides/educators describe and interpret their professional lives after having established family lives involving childcare.

Methods: The analysis is based on qualitative research interviews of five full-time outdoor guides and educators aged between 33 and 40 (born between 1969 –1975). The informants estimate about 70 to 200 working days per year spent away from home. Other key figures are an average professional history of 8,4 years, married or living together with an average of 1,5 children of mean age 5,6 years old. These families produce a mean total of 1,8 human-labour years, varying between 1,35 to 2,15 human-labour years. The informants have an average of 6,4 years university college education in outdoor life and specialized outdoor training through courses.

Analysis/Discussion: These professional outdoor guides/educators all describe a self-perceived inherent need to be active in the outdoors and the type of work is extremely time consuming. A pattern emerges showing that the driving force for choice of profession is a passion for being outdoors and an allure of doing outdoor activities. The informants have chosen a lifestyle and type of work that commits them to full-time mentoring, guiding and teaching others in demanding 'natural' environments; often synonymous with high mountainous areas. A passion has become professionalized. Their subjective experiences during work substantiate the amount of time used at work. Also fatherhood is expressed to be important; they want to be present and to develop close relationships with their children. The everyday challenge is how to cope with combining the two roles and life spheres. This material reveals four different strategies for balancing between an alluring form of work and the ideal of being a present father: 1) Change in work patterns, 2) Change around work patterns, 3) Departure from the distinctive character of this work, and 4) tending toward a re-orientation away from work as a fulltime outdoor educators as primary.

THE NEW MEDIA AND HOOLIGANISM: CONSTRUCTING MEDIA IDENTITIES.

AAGE, R.

SPORT SCIENCES

This paper will focus on the new media, for the most part Internet. The main target is the production of the picture of hooliganism on Internet, as well as the consumption of this "picture". The paper, will thereby, examine the relation between "the new media" and "hooliganism". This discussion will be related to an analysis of the website www.sverigescenen.com, a Swedish online magazine. A central question is: How are different pictures/images of the hooligans constructed and described in the new media landscape.

In this respect, Nordic criminologists have informed about the power and the influence of media. They have - close to a moral panic - uphold various social evils that have normally and frequently been related to the power of media in general. This power can be used to induce a fear amongst ordinary people; a fear of criminal act. This influence on the moral discourse could, in the extension, maintain a fear that is out of all proportion to actual risks. Previous research has in general indicated that mass media has a great impact on the (re-)production of the "narrative stories" of hooliganism and hooligans.

Importantly, the new media landscape creates new conditions for this "narrative picture" of hooliganism, due to the fact that both supporters and the hooligans themselves are active and vigorous media producers. This 'new' situation of participation/engagement involvement in the media production will expand and transform the research on the media process, focusing both on producing and consuming media. In this light, he modern media construction of hooliganism stand out as an important subject.

GENDERED DISCOURSES OF WOMEN'S GOLF: MICHELLE WIEUPSTART SHUTDOWN

BIALOWAS, A.
WEBER STATE UNIVERSITY

In February of 2003, Annika Sorenstam was invited to play in the Bank of America Colonial PGA event in the United States. It was the first time since 1945 that a woman played in a PGA (Professional Golf Association) golf event—a tour reserved for male play. Also in 2003, Michelle Wie was invited, with an exemption, to play in the 2003 Boise Open on the male-only Nationwide Tour. Michelle Wie's continued attempts on the PGA Tour, in addition to other exclusively male tournaments, posed a sustained challenge to the conventionally gendered discourse of golf. This paper investigates the gendered rhetorical construction of golf within U.S. public discourses to understand how challenges to and transgressions from the dominant sport narrative are negotiated and managed in the public discourse.

My primary methodological tool is feminist rhetorical criticism informed by critical theoretical approaches. Through identifying gendered patterns, performances, narratives, and themes of Michelle Wie, along with intersections of gender with race, class, ethnicity, age, and sexuality, I assess the ways in which the U.S. public discourse characterized her play against men and track how the established character of golf—as fundamentally a discourse of privileged white heterosexual masculinity—was positioned in relation to Wie. The texts that I analyzed came from various arenas of U.S. public discourse. They include: (a) newspapers, such as The New York Times (b) magazines, including Sports Illustrated and Golf Magazine (c) televised tournaments (d) and PGA and LPGA promotional literature. The time frame for analysis is from January 2002 to December 2007, which covers the span of time prior to Wie's first invitation to play against men and after one of the last times that she competed against men. By analyzing a variety of texts over a long period of time, I can identify rhetorical patterns and strategies pervasive in the U.S public discourse.

In the case of Michelle Wie, traditional strategies designed to minimize the presence of female athletes, were not employed. Instead, other rhetorical strategies were apparent with regard to how the public discourse of golf rhetorically constituted Wie's gender as it intersected with race, class, and sexuality. Analysis revealed five major themes/patterns: First, Wie was portrayed as a publicity stunt; second, she was portrayed as an interesting, anomalous "specimen" in ways that negated her status as a "real" golfer; third, her youth and naïveté were portrayed as the basis of her career, and thus inevitably transient; fourth, she was made into a moral "spectacle" in ways that eroded her depth and substance, personally and professionally, as well as alluded to her "difference"; and finally, she was articulated as a political token, a mechanism or vehicle for others' (especially her parents') ambitions and agendas.

DISCURSIVE CONSTRUCTIONS OF GIRLS IN A SPORTS INITIATIVE.

SVENDER, J.
INSTITUTION OF SPORT AND HEALTH

The Swedish Sports Confederation has a long-standing and implicit contract with the state to the effect that sport receives national resources in exchange for the staging of activities that are open to all and organised in such a way that children and young people are brought up to be good and democratic citizens (SOU, 2008). One social issue expressed in the sports movement's programme, and one of the premises for state support, is gender equality. Several plans and projects have been carried out in order to provide equal sporting opportunities for men and women. The research project investigates one of these initiatives, in which local sport clubs were encouraged by the state to promote girl's sports participation.

Singling out girls – and not boys – as special targets is reasonable considering that sport has been, and still is, discursively positioned as a masculine practice (e.g. Chase, 2006; Larsson, 2003). In addition, quite often different forms of problematic issues have been linked with girls' sports participation. This motivates a study on ideas of girls and their sports participation. The presentation will scrutinise issues associated with girls' sports participation that legitimise special promotion.

The aim of the study is to analyse the discursive constructions of girls in projects designed by local sports clubs in three traditional female-dominated sports: equestrian sport, figure skating and gymnastics. The framework is inspired by a feminist Foucauldian perspective in which concepts of power and governmentality are central (Foucault, 1994). Governmentality implies a complex relationship between the exercise of power and knowledge about the object of governing. The study question relates to ideas and knowledge about girls portrayed by the sports clubs. The methodology undertaken is discourses analysis of the project applications, written and submitted by local sports clubs. Different ways of framing girls and their sports participation are sought by identifying patterns and regularities in the applications, and considering which different actions are legitimised, promoted or imposed in the texts. The result shows that the project presupposes certain kinds of girls, namely, those linked with notions about what becoming a teenage girl means.

FOOTBALL - SCIENCE OR PLAY AND PASSION: NORWAY WITH OR WITHOUT 'DRILLO'

SKOGVANG, B.O.
HEDMARK UNIVERSITY COLLEGE

Football has been linked to science for a long time through that traditional sciences' like psychology, medicine, pedagogy etc. have been applied on football. To change football from play and passion to science has been seen as negative both in Norway and England, and the football practice has in general been seen as conservative and negative to theory (Larsen 2001). Publications from the conferences 'Science and Football' and Richard Giulianotti (1999) bring voices to this debate. I will bring in findings in the project; 'Elite football – a field of changes' (Skogvang, 2006) where I have done observations in international championships, observations of practices, meetings, and matches in three elite football clubs through a year, plus interviews with 22 players (11 of each sex) and eight coaches in women's and men's football. The project discuss different areas within Norwegian elite football; like professionalism, the media and commercialisation, the players' experience of their own and others football practice etc. Here I will put focus on the ongoing debate in the Norwegian field (Bourdieu 1993) of football, where often a dichotomy between two poles is visual. On the one hand football is seen as play, emotions,

entertainment and passion. On the other hand we have the scientific football. I will discuss this and connect it to the link between science and practice and how science can influence the football practice for women and men both at elite and grass root level.

Goksøyr and Olstad (2002) describe how elite football in Norway did turn from 'self-taught practitioners' to more accept for theory and science. Egil "Drillo" Olsen, who was educated and employed at the Norwegian School of Sport Sciences, was a skilled football player, and is seen as 'the embodied' person for football science in Norway. Olstad and Goksøyr (2003) call him 'the Fridjof Nansen of the 1990s', and describe the three waves of intense discussion about how football is to be played in Norway. In January 2009 "Drillo" again became the manager of the Norwegian male national team. The 0-1 victory away against Germany in Drillo's first match actualised the debate about football and science or the passion and play with the ball again.

URINARY CC16 LEVELS IN WINTER VERSUS SUMMER SPORT ATHLETES AFTER EUCAPNIC VOLUNTARY HYPERPNOEA

BOLGER, C., TUFVESSON, E., STENFORS, N., DEVEREUX, G., AYRES, J.G., HOLMBERG, H.C., BJERMER, L., SUE-CHU, M., KIPPELEN, P.

UNIVERSITY OF ABERDEEN

Exercise−induced bronchoconstriction (EIB) is highly prevalent in elite athletes, especially in those training in cold dry environments (1). Dehydration of the airways plays a key role in this process (2). EIB has recently been linked to airway epithelial injury in asthmatic individuals (3).

The aim of the study is to determine whether a short period of hyperpnoea of dry air causes airway epithelial disruption in winter and/or summer sport athletes. We hypothesise that urinary level of the Clara cell protein (CC16) – an indirect marker of permeability/cellular integrity of the lung epithelial barrier (4) – will be increased after a eucapnic voluntary hyperpnoea (EVH) test and that this increase will be larger in winter compared to summer athletes.

Forty two female athletes – 28 summer athletes (age 31.1+/-1.7yr (SEM), training volume 9+/-1.1h/wk) and 14 winter athletes (age 21.4+/-0.8yr, training volume 12.0 ± 1.10h/wk) – took part in this study. They all performed an 8-min EVH test at a target ventilation rate of 30 times their baseline forced expiratory volume in one second (FEV1). After the challenge, FEV1 was measured in duplicate at 2, 5, 10, 15, 20, 30, 60 and 90min. A sustained decrease in FEV1 of at least 10% from baseline was considered positive. Urine samples were collected at baseline and at 30, 60 and 90min recovery. CC16 concentration was measured by enzyme immunoassay.

Ten summer athletes had a positive test (max FEV1 fall = 19.6+/-2.4%), whilst eighteen of the summer athletes and all the winter athletes were negative (max FEV1 fall = 5.7+/-0.7% and 5.3+/-0.7%, respectively). CC16 increased significantly after the challenge in all three groups (P<0.01) with no difference between groups: delta CC16 (max post-EVH minus baseline) in summer EVH negative athletes was 0.241+/-0.1 ng/μmol creatinine, 0.292+/-0.085 ng/μmol creatinine in summer EVH positive athletes, and 0.123+/-0.047ng/μmol creatinine in winter EVH negative athletes (P=0.415).

In conclusion, a short period of hyperpnoea of dry air is associated with an increased rate of CC16 excretion in urine in both winter and summer athletes. This suggests that the integrity of the airway epithelium might be compromised by loss of airway surface lining fluid when athletes inhale dry air at high flow rates. This appears to occur irrespective of the degree of bronchoconstriction or regular training environment.

NO EFFECT OF AGE, GENDER AND PHYSICAL ACTIVITY LEVEL ON HUMAN MONOCYTE TOLL-LIKE RECEPTOR 4 EXPRESSION IN AN ACTIVE POPULATION

OLIVEIRA, M., GLEESON, M.

LOUGHBOROUGH UNIVERSITY

Several studies have reported that some immune cell functions including monocyte Toll-like receptor (TLR) expression are temporarily reduced after a prolonged acute bout of strenuous exercise, and that several months of moderate exercise training in previously sedentary individuals results in reduced levels of TLR expression (Gleeson et al. 2006). Over the long term these effects may be beneficial to health due to associated reductions in chronic inflammation, and consequently reducing the risk of developing chronic metabolic and cardiovascular diseases. To date, there has been little research on the effect of habitual activity level on human monocyte TLR expression

or the influence of age or gender apart from one study (McFarlin et al. 2006) that showed a lower TLR4 expression in active compared with sedentary subjects in both a young and an elderly population.

The purpose of this study was to examine the effects of the volume of self-reported moderate-strenuous exercise training on human monocyte TLR4 expression in a large cohort of active subjects (minimum of 3 hours moderate-strenuous training per week). With local ethics committee approval 85 healthy subjects aged 18-53 yrs, body mass 52-112 kg; BMI 18-35 kg/m2 completed a self-report questionnaire of weekly exercise training load and a resting venous blood sample (following an overnight fast) was taken for analysis of circulating monocyte counts and TLR4 expression (corrected for non-specific binding using an isotype control) as described by Lancaster et al. (2005). TLR4 expression was compared in males and females matched for habitual activity level, young and older subjects matched for habitual activity level and subjects classed according to hours of training per week (3-7 , 8-14 and 15-25 h/week). T-test and ANOVA were used to analyse the data.

Monocyte counts were in the normal range for all subjects and were not influenced by age, gender or habitual activity level. Monocyte TLR4 expression (geometric mean fluorescence intensity, GMFI, mean [SEM]) was not affected by age (GMFI: 20.4 [1.5] in 47 subjects aged 18-24 yrs versus 23.7 [2.3] in 23 subjects aged 30-53 yrs, P=0.240) or gender (GMFI: 19.7 [1.2] in 52 men versus 23.7 [2.3] in 31 women, P=0.096). There was no significant main effect for physical activity level for TLR4 expression (F = 0.805, P=0.451) which was 22.2 [2.1], 21.8 [1.6] and 18.6 [1.3] (GMFI) in subjects exercising for 3-7, 8-14 and 15-25 h/week, respectively.

This study showed that TLR4 expression is not affected by exercise training load, gender or age in a physically active population.

VALIDATION OF INFRARED THERMOGRAPHY AS INJURY PREVENTION METHOD IN PROFESSIONAL SOCCER PLAYERS.

GÓMEZ, P., NOYA, J., NUÑEZ, J., FERNANDEZ, I., SILLERO, M.

1. FACULTY OF PHYSICAL ACTIVITY AND SPORT SCIENCES-INEF. UNIVERSIDAD POLITÉCNICA DE MADRID (UPM), 2. VF SPORT, 3. REAL ZARAGOZA CF, SAD

Introduction.

Tensiomiography (TMG) is been used as an injury prevention method in professional soccer players. It records the muscle response to a known electrical stimulus intensity [1,2]. In other hand, Thermography (TG) is a technique used for detecting and managing injuries [3], in which a camera records the infrared radiation released from the metabolic activity of human body for estimating temperatures on different areas [4]. This study attempts to correlate both techniques in order to validate the TG as an injury prevention method in professional footballers.

Methods: Using a Tensiomyographer (TMG 100 Measurement System, TGM - BMC Ltd.) and a Thermographic camera (ThermaCAM TM SC640, FLIR SYSTEMS), 20 professional Spanish soccer players were assessed the day after the weekly competition. They were recorded 5 variables by TMG (Delay Time [DT], Contraction Time [CT], Sustain Time [ST], Relaxation Time [RT] y Maximal Displacement [MxD]) in both Femoral Biceps (dominant [DFB] and non-dominant [NDFB]). Previously, it had been obtained the mean temperatures (T) of those areas by TG.

Results: Student T-test showed lack of significant differences between DFB and NDFB for all recorded variables (DTDBF = 26.7, DTNDBF = 27.5; CTDBF = 32.2, CTNDBF = 34.3; STDBF = 191.5, STNDBF = 199.8; RTDBF = 56.5, RTNDBF = 56.0; MxDDBF = 5.8, MxDNDBF = 5.7; TDBF = 33.8, TNDBF = 33.9). Indirect significant correlations were found between T and CT ($r = -0.35$; $p < 0.05$) and DT ($r = -0.39$; $p < 0.05$) considering together the results of both Femoral Biceps and, dividing the data in DFB and NDFB, they were found indirect significant differences between T and STDBF ($r = -0.50$; $p < 0.05$) and between T and CTNDBF ($r = -0.45$; $p < 0.05$) and DTNDBF ($r = -0.49$; $p < 0.05$). Considering individual cases, TG reach similar results compared with TMG on the injury risk for each player.

Discussion and Conclusion.

Differences on the significant variables for the dominant leg may be due to different contraction pattern or function during the game or to different injuries prevalence for each leg. However, TG may be considered as a valid method in order to assess the injury risk of a professional soccer player.

INFLUENCE OF COLD WATER FACE IMMERSION ON POST-EXERCISE PARASYMPATHETIC REACTIVATION

AL HADDAD, H., AHMAIDI, S., BUCHHEIT, M.

RESEARCH LABORATORY, EA-3300 «LABORATORY OF EXERCISE PHYSIOLOGY AND REHABILITATION», FACULTY OF SPORT SCIENCES, UNIVERSITY OF PICARDIE, JULES VERNE, 80025, AMIENS, FRANCE.

Introduction: A delayed parasympathetic reactivation after exercise is associated with an increased risk of sudden cardiac death. Thus, means of improving post-exercise parasympathetic reactivation are now receiving greater interest. Hayashi et al. (1997) showed that cold water face immersion (CWFI) can increase vagal activity (i.e., inferred from heart rate (HR) variability (HRV)) at rest, but whether this beneficial effect is preserved during recovery after exercise is not known. Therefore, the aim of the present study was to investigate the effect of CWFI on parasympathetic reactivation following exercise.

Methods: Eleven men (21.6±1.3 yr; 1.80±0.06 m; 76.1±13.0 Kg) performed, on two different occasions, an intermittent exercise (i.e., a cycling 30-s Wingate test (to reduce vagal activity) followed by a 5-min run at 60% of maximal aerobic velocity, interspersed with 5-min of seated recovery). Immediately after the 5-min run, participants underwent a seated passive recovery with either CWFI or without (C) condition. Participants breathed through a snorkel in both recovery conditions. In CWFI condition, water temperature was kept at 10-12°C. Parasympathetic reactivation was assessed through beat-to-beat HR collection (Polar Electro, Kempele, Finland) during the 5-min following the submaximal exercise (Buchheit et al., 2007). Absolute HR recovery was calculated from the immediate 60s period after exercise

(HRR60s), and HRV vagal-related indices (i.e., natural logarithm of high frequency, LnHF and the root mean square of successive R-R interval differences, RMSSD) were calculated on the last stationary 3-min segment. Data were compared by paired t-test.

Results: CWFI induced faster HRR60s compared to C (44.4±4.1 vs. 31.4±2.7 bpm, p=0.008). Compared to C, all vagal-related indices were significantly higher during CWFI (LnHF: 4.5±0.6 vs. 2.9±0.4 ms², p=0.004; RMSSD: 24.4±11.7 vs. 8.8±2.0 ms, p=0.02).

Discussion: This study is the first to assess the effect of CWFI immediately after exercise on parasympathetic reactivation. In accordance with previous studies showing CWFI to trigger parasympathetic heart control at rest (i.e., with no previous exercise, (Hayashi et al., 1997)), our results showed a faster increase in post-exercise vagal-related indices in the CWFI compared to the control condition. CWFI appears to be a simple and effective means to accelerate post-exercise parasympathetic reactivation.

EXERCISE-BASED SPORTS INJURY PREVENTION: A SYSTEMATIC REVIEW

HÜBSCHER, M., ZECH, A., PFEIFER, K., HÄNSEL, F., VOGT, L., BANZER, W.

1. GOETHE-UNIVERSITY FRANKFURT/MAIN, 2. UNIVERSITY OF ERLANGEN-NUREMBERG, 3. UNIVERSITY OF DARMSTADT

Introduction: Sports injuries are often associated with increased morbidity and disability, and therefore constitute a major public health burden. Although exercise programs targeting the enhancement of proprioceptive and neuromuscular abilities have widely been considered for injury prevention, uncertainty remains about the most appropriate types of exercise and their (relative) effectiveness. Therefore, the aim of this systematic review was to assess the effectiveness of proprioceptive/neuromuscular training in preventing sports injuries by using the best available evidence from methodologically well-conducted randomized controlled trials (RCTs) and controlled clinical trials without randomization (CCTs).

Methods: At least 2 independent researchers performed a search for articles published between 1966 and 2008 in Cochrane, MEDLINE, EMBASE and PEDro databases. The reviewers independently assessed articles for eligibility, extracted data, and assessed methodologic quality using the van Tulder criteria list. Relative Risks (RR) and 95% confidence intervals (CI) were used to estimate treatment effects. Heterogeneity between studies was examined by using the Q and I-squared statistics. Where applicable, fixed effects and random effects models were used for meta-analysis.

Results: From a total of 32 relevant studies, 7 methodologically well-conducted RCTs (i.e. studies that adequately fulfilled and reported at least 50% of the quality criteria) of adolescent and young adult athletes (7633 participants) practicing ball sports were considered for this review. Exercise interventions included balance training or multi-intervention-programs comprising balance training, stretching, plyometrics, running exercises, cutting and landing technique and strength training. Pooled analysis revealed that multi-intervention training was effective in reducing the risk of acute knee injuries (RR 0.46, 95% CI 0.28-0.76; p<.01), and ankle sprain injuries (RR 0.50, 95% CI 0.31-0.79, p<.01). While balance training was also effective in reducing the risk of ankle sprain injuries (RR 0.64, 95% CI 0.46-0.9; p<.01), it showed a non-significant risk reduction for injuries overall (RR 0.49, 95% CI 0.13-1.8; p=.28). Individual studies found that exercise interventions were more effective in athletes with a history of sports injury than in those without.

Discussion: This systematic review and meta-analysis comprises data from 7 high-quality RCTs that may be the basis for evidence-based sports injury prevention. The results suggest that balance exercises and multi-intervention training programs alike can be effective in reducing the incidence of certain types of sports injuries among adolescent and young adult athletes during pivoting sports. Future research should focus on the conduct of comparative trials to identify the most appropriate and effective training components for preventing injuries in different sports and populations.

COMPARISON OF SEMINAL SUPEROXIDE DISMUTASE <SOD> ACTIVITY BETWEEN ELITE ATHLETES, ACTIVE AND NON ACTIVE MEN

ABBASI, A., TARTIBIAN, B., HAJIZADEH, B., NORTHOFF, H.

1. INSTITUTE OF CLINICAL AND EXPERIMENTAL TRANSFUSION MEDICINE (IKET), UNIVERSITY OF TUEBINGEN, TUEBINGEN, GERMANY 2. DEPARTMENT OF SPORT SCIENCE, URMIA UNIVERSITY, URMIA, IRAN

Introduction: Superoxide dismutase as an important element of seminal plasma superoxide anion scavenging capacity plays an essential role in maintaining the balance between ROS generation and degradation, and hence male fertility. The purpose of this study was to evaluate the seminal plasma SOD activity of individuals with different level of physical fitness.

Methods: A total of 40 semen samples were obtained from 3 groups of men, including elite athletes (mean age 23.1±1.3 yrs, n=15) who had regular training (4-5 days per week), physically active (mean age 23.4±0.9 yrs, n=13) who were participating in educational or recreational physical activities for 4-5 h per week, and sedentary controls (mean age 22.0 ±2.0 yrs, n=12) who did not participated in any exercise program for at least 6 months prior to study.

Results: The result showed significantly higher SOD activity in seminal plasma of elite athletes, as compared with those of recreationally active (P= 0.001) and control (P=0.004) groups. No statistically significant difference was observed between active and control groups (P=0.139).

Discussion: Therefore, the results of the present study demonstrate that, compared to sedentary and recreationally active men, elite athletes develop an increased seminal antioxidant capacity in term of SOD level, suggesting that spermatozoa from elite athletes may be less susceptible to ROS- induced peroxidative damage, and hence, infertility. Further studies are warranted to detail the antioxidant capacity of seminal plasma and spermatozoa of individuals with different levels of physical fitness as well as the effect of various exercise programs on seminal antioxidant capacity.

IS-SS03 Performing under pressure in sport

CHOKING AS THE WORLD IS WATCHING: EVIDENCE FROM MAJOR FOOTBALL PENALTY SHOOTOUTS

JORDET, G.

NORWEGIAN SCHOOL OF SPORT SCIENCES

CHOKING AS THE WORLD IS WATCHING: EVIDENCE FROM MAJOR FOOTBALL PENALTY SHOOTOUTS

Jordet, G.

Norwegian School of Sport Sciences, Oslo, Norway

The football (soccer) penalty shootout is used to identify a winner when two teams are tied in tournaments. Given that this event is known as a vast pressure situation where shooters typically are assumed to have an advantage over the keeper (goals are typically scored on 70-80% of the shots), the shooters' failure to live up to expectations of scoring may indicate that choking has taken place. In this presentation, I present multiple studies that document different aspects of choking under pressure in international penalty shootouts. First, in-depth interviews with 10 players who took part in a European Championships penalty shootout indicate that a large majority of the players experience competitive anxiety in this situation, and that a considerable number of them experiences little control over the outcome (which is linked to both high anxiety intensity and negative directional interpretation of anxiety symptoms). Second, match record and video evidence from all penalty shootouts ever held in the World Cup, European Championships, and UEFA Champions League suggests that the number of misses increases with elevated shot importance. In addition, the number of misses becomes even higher on shots with negative valence (i.e., shots where a miss instantly produces a loss) as compared to shots with positive valence (i.e., shots where a goal instantly produces a win). Players also engage more in avoidance based coping strategies (diverting their gaze away from the goal and rushing their preparations to get the situation more quickly over with) when they perform in these high-pressure situations. Third, players with high public status score fewer goals than players with less status, suggesting that high egotism can precipitate choking on this task. The same is found with respect to team status, where players on teams with high international status score fewer goals and engage more in escape strategies than players on other teams. In conclusion, the results from these studies are consistent with a view of choking under pressure as related to favourable views of self under threat. Performers then underachieve when they engage in self-defeating self-regulation strategies initiated to escape from the unpleasant affect associated with the pressure. The presentation is ended with a discussion of a real-world intervention where some of the knowledge generated from this research was put to practice by the Dutch U21 team in a penalty shootout in the 2007 European Championships.

TO BE OR NOT TO BE? SELF-CONSCIOUSNESS, EXPLICIT MONITORING AND SKILL FAILURE UNDER PRESSURE

JACKSON, R.C., ASHFORD, K.J., KINRADE, N.P, ADAMS, D.

BRUNEL UNIVERSITY

Baumeister (1984) proposed that, under pressure, performers attempt to control their skills consciously but that "consciousness does not contain the knowledge of these skills, so that it ironically reduces the reliability and success of the performance" (pp. 610-611). Over the past 25 years, considerable support for this idea has been found by researchers examining 'choking' in motor skills, couched in terms such as reinvestment and explicit monitoring. In this presentation, I will further examine the role of conscious processing in skill failure by considering (i) the function of the explicit focus, (ii) individual propensity for reinvestment, and (iii) the nature of the task. First, I will consider the function and level of conscious control that is implicated in skill failure by looking at the different types of process goal and their effect on skilled motor performance. From the applied perspective, I will also consider the complex nature of foci described by elite performers, and whether they are deemed to be facilitative or debilitative. I will discuss these data in terms of their implications for preventing skill failure under stress. Second, I will present data regarding the relationship between dispositional self-focus and performance under pressure in cognitive tasks of varying complexity. In so doing, I will consider the possibility that reinvesting conscious control can also have a detrimental effect on the more cognitive or perceptual elements of skilled performance. This has implications for skilled decision making in sport, which requires accurate judgments to be made in a time-constrained environment.

STRESSORS, SOCIAL SUPPORT, AND PERFORMANCE

REES, T.

UNIVERSITY OF EXETER

When faced with the pressure surrounding competing in sport, some athletes may feel they should "go it alone." The recommendations from the sport psychology literature are, alternatively, that athletes should be encouraged to be proactive in harnessing social support from those around them. Although research on social support in sport has tended to be limited to its influence on sport injury, there is an emerging literature base focusing on its influence within performance settings (for a review, see Rees, 2007). For example, there is recent

evidence that social support may explain as much as 24% of the variance in performance over and above the variance explained by performance-related stressors (Rees, Hardy, & Freeman, 2007). This offers a very powerful indication of the impact social support may have in relation to sports performance. Generally, two principal models identify the conditions under which different kinds of social support influence outcomes (and thus performance): the stress-buffering model, and the main (or direct) effect model. The main effect model proposes that social support has a beneficial effect irrespective of whether persons are under stress. Stress-buffering is tied to models of the stress process, appraisal and coping. The stress-buffering influence of social support might operate by leading to benign appraisal of the stressful events, through a direct transfer of resources, or by promoting better coping behaviors. The role of social support in this process will be discussed in relation to recent work within sports performance, which has demonstrated that the stress-buffering model may be mediated by self-efficacy (Rees & Freeman, 2009), that social support may operate through challenge and threat appraisals (Freeman & Rees, in press), that both perceptions and receipt of support should be taken into account (Freeman & Rees, 2008), and that focused interventions can lead to increased social support and improved performance (Freeman, Rees, & Hardy, in press). Future research directions and the applied implications for sportspeople performing under pressure will then be discussed.

IS-SM02 Physical activity and ageing

STRATEGIES FOR THE PROMOTION OF PHYSICAL ACTIVITY AMONG OLDER PEOPLE IN EUROPE - THE EUNAAPA PROJECT

RÜTTEN, A., GELIUS, P., ABU-OMAR, K.

INSTITUTE OF SPORT SCIENCE AND SPORT, FA UNIVERSITY ERLANGEN-NUREMBERG, GERMANY

The European Network for Action on Ageing and Physical Activity (EUNAAPA) project pursued the identification of successful strategies for the promotion of physical activity among older people. The project was funded by the Directorate General Health and Consumer Protection of the European Commission, 21 institutions from 16 European nations (Austria, Belgium, Czech Republic, Denmark, Finland, France, Germany, Great Britain, Greece, Italy, the Netherlands, Norway, Poland, Portugal, Spain, and Sweden) took part in the project work from 2006 to 2008.

In order to assess existing policies for the promotion of physical activity among older people in participating nations, a mini-survey with a total of 248 policymakers was conducted. A sampling matrix was developed to define policy sectors (e.g. sports, health, social welfare) and governance levels from which respondents were recruited for interviews. The matrix was developed to allow for structural equivalence in the comparison of policies across nations. The survey contained questions on goals, obligations, resources and opportunities that policymakers perceived for the development of policies in the area of physical activity promotion among older people. These four determinants of policy making are based on a theoretical model developed by v. Wright (1976) that has been adapted to assess determinants of health promotion policies (Rütten et al. 2000).

Results of the survey indicated that determinants of policy outcomes for physical activity promotion among older people varied starkly among participating nations. Across nations, policy makers rated available resources as most critical compared to the other the determinants. Interestingly, policy makers in some nations reported lacking concrete goals for policy development. Policy makers in a number of nations indicated that opportunities (e.g. interest of the media in the topic of ageing and physical activity) had improved in recent years. National workshops with policymakers were utilized to discuss, based on results of the survey, strategies for policy development for physical activity promotion among older people.

DO'S AND DONTS IN PHYSICAL ACTIVITY RESEARCH AMONG CHRONICALLY ILL OLDER PERSONS

HOPMAN-ROCK, M.

TNO QUALITY OF LIFE AND BODY@WORK RESEARCHCENTER TNO VU UNIVERSITY MEDICAL CENTER

From literature reviews on research in physical activity (PA) and exercise in chronically ill older persons it is known that a lot of the published research has not the highest scientific standard. What is the reason for that finding and how may we improve that? Because evidence based interventions are important to ensure implementation effects in sports and exercise practice, these are important questions. During the presentation reasons will be explored why randomized controlled trials in this area are relatively difficult to perform. Examples from own experiences will be given from research on PA and exercise in older persons with dementia, mild cognitive impairment, osteoarthritis of the hip and/or knee and incontinence problems.

PROMOTING PHYSICAL ACTIVITY IN OLDER ADULTS: A LIFESTYLE APPROACH OR A STRUCTURED EXERCISE INTERVENTION?

DELECLUSE, C., VAN ROIE, E., OPDENACKER, J., BOEN, F.
FACULTY OF KINESIOLOGY AND REHABILITATION SCIENCES

INTRODUCTION: Several studies have shown that older persons benefit from a supervised, center-based, exercise program in terms of improved functional performance and fitness (Delecluse et al., 2004; Dunn et al., 1998; Fahlman et al., 2007). However, these supervised center-based programs are expensive, which limits their implementation possibilities and hence their public health impact. Moreover, for sedentary older adults in particular, a number of important barriers exist to attend such supervised center-based exercise program, for example lack of access or transportation to the facilities, financial considerations and a lack of affinity with the culture of fitness centres (Schutzer & Graves, 2004). In order to deal with these barriers, home-based and lifestyle interventions were developed. However, it is not yet clear whether the effects of such home-based and lifestyle interventions equal the effects of supervised center-based exercise interventions. The aim of this study was to evaluate the effects of traditional fitness training intervention versus a home-based lifestyle intervention on physical activity, physical fitness and cardiovascular risk factors in older adults.

METHODS: One hundred and eighty-six sedentary men and women aged 60 to 83 volunteered to participate and were randomized in one of three groups. A fitness training intervention (STRU, N = 60), consisting of three supervised sessions weekly, and a home-based group (LIFE, N = 60), including an individualized lifestyle program supported by a limited number of booster phone calls, were compared with an 'assessment only' control group (N = 66). Physical activity, cardio-respiratory fitness, muscular fitness, functional performance and cardiovascular risk factors were recorded before (pretest) and after 11 months of intervention (posttest).

RESULTS and CONCLUSIONS: The STRU and the LIFE intervention were equally effective in increasing physical activity in older adults. Both intervention groups improved in physical fitness, but STRU increased more than LIFE for cardio-respiratory and muscular fitness, whereas LIFE increased more than STRU for functional performance. In general however, although STRU showed a limited effect on body composition and total cholesterol/HDL ratio, eleven months of structured exercise and/or lifestyle physical activity had only limited effects on cardiovascular risk factors,. Therefore, interventions aiming to reduce cardiovascular risks should focus on long-term changes in physical activity behaviour.

IS-PH01 Skeletal muscle blood flow regulation during exercise

EXERCISE HYPEREMIA: PARTITIONING THE PERIPHERAL AND CENTRAL FACTORS

RICHARDSON, R.
UNIVERSITY OF UTAH

Numerous factors contribute to the essential increase in blood flow to active skeletal muscle at the onset of exercise, ensuring the adequate supply of oxygen and removal of metabolic by-products. Central and peripheral factors, which may include the skeletal-muscle pump, mechanically induced vasodilation, mechanical distortion of arterioles, flow mediated dilation, and cardio-acceleration resulting from muscle mechanoreptor and chemoreceptor feedback, all have substantial support for their role in this hyperemic response. However, as a result of the copious factors, it is difficult to experimentally partition them allowing one to determine the magnitude of effect and temporal nature of any single mechanism. Thus, the aim of this presentation will be first to examine the blood flow response to exercise and then to subsequently highlight the, second by second, kinetics of central and peripheral factors that influence hyperemia at the onset of limb movement, providing mechanistic insight into the regulation of exercise hyperemia.

ROLE OF INTRAVASCULAR SIGNALS ON THE CONTROL OF MUSCLE PERFUSION

GONZÁLEZ-ALONSO, J.
BRUNEL UNIVERSITY

The matching of skeletal muscle oxygen supply and demand is a fundamental principle in Physiology. Recent studies suggest that the oxygen carrying erythrocyte plays a role in this process by sensing and signaling the amount of oxygen bound to hemoglobin, i.e., oxyhemoglobin (O2Hb). In this construct, adenosine triphosphate (ATP) release from erythrocytes in association with the offloading of oxygen from the hemoglobin molecule is thought to play an important role in the matching of oxygen delivery to local muscle metabolic demand. In vitro and in vivo observations support this hypothesis by demonstrating that i) erythrocytes release ATP in association with the offloading of oxygen from the hemoglobin molecule, ii) plasma ATP is tightly correlated to alterations in O2Hb with exposure to hypoxia, hyperoxia and carbon monoxide inhalation, and iii) ATP, when infused intra-arterially, causes both marked muscle vasodilatation and complete inhibition of alpha-adrenergic vasocontriction. ATP exerts its vasodilatory effect directly and not via degradation compounds, as comparison of the relative vasoactive potencies of ATP, and other nucleotides (ADP, AMP), adenosine and UTP, reveals the following rank order of vasoactive potency: ATP (100) = UTP (100) >> adenosine (5.8) >ADP (2.7) >AMP (1.7). Furthermore, both ATP and UTP, but not ADP, AMP or adenosine infusions, fully inhibit alpha-adrenergic vasoconstriction in a manner similar to exercise and hypoxia. Human skeletal muscle expresses mainly P2Y2 purinergic receptors located in the vascular endothelium. The P2Y4, the only common ATP/UTP receptor, cannot be detected at the mRNA level in skeletal muscle. Taken together, these findings support that erythrocyte-derived ATP acts as an important mediator of oxygen sensing transduction between the erythrocyte and the muscle vascular endothelium causing both vaso-

dilatation and sympatholysis by binding to endothelial ATP selective P2Y2 purinergic receptors and stimulating the vascular endothelium to release vasodilator-sympatholytic substances, including nitric oxide, prostaglandins and endothelium-derived hyperpolarization factors.

ROLE OF ENDOTHELIUM AND SKELETAL MUSCLE DERIVED VASODILATORS

HELLSTEN, Y.

UNIVERSITY OF COPENHAGEN

Role of endothelium and skeletal muscle derived vasodilators
in exercise hyperaemia
Ylva Hellsten
Copenhagen Muscle Research Centre, Department of Exercise and Sport Science, University of Copenhagen, Universitetsparken 13, DK-2100 Copenhagen Denmark

In skeletal muscle, blood flow may increase more than 30-fold from rest to exercise, with a close match between the rate of flow and oxygen demand. The precise regulation is achieved by a balance between sympathetic vasoconstriction and locally formed vasodilators, but also vasoconstrictors and compounds that induce sympatholysis are involved . Studies using pharmacological inhibition of single or multiple vasodilator systems in humans have revealed that the compounds nitric oxide (NO), prostaglandins (PG's), 11, 12 eicosatrienoic acid (11, 12 EETs), adenosine and ATP are regulators of muscle blood flow. Such studies have also demonstrated that there is interaction between vasodilators where a specific vasodilator can compensate for the impaired release of another, i.e. redundancy. Evidence for redundancy exists between NO and PG's and between NO and 11, 12 EETs. In addition, some compounds exert or extend their vasoactive effects by inducing the release of vasodilators. Examples of this are the effects of ATP and adenosine in causing the release of NO and PG's. In fact, evidence point at that release of nitric oxide and prostaglandins is the primary mechanism by which adenosine regulates exercise hyperaemia and that a direct effect of adenosine on adenosine receptors on smooth muscle cells appear to be of less importance. Thus, several vasodilators of importance for muscle blood flow control have been identified and evidence point at that the precise regulation of flow is the result of a close interplay between these vasodilators. Nevertheless, simultaneous inhibition of multiple known vasodilator systems has only been found to reduce exercise hyperemia in humans by ~30%, which could suggest the existence of yet unidentified vasodilators.

IS-BM08 Laterality and assymetries in sports

MECHANISMS UNDERLYING FUNCTIONAL CHANGES IN THE PRIMARY MOTOR CORTEX IPSILATERAL TO AN ACTIVE ARM

PEREZ, M.A.

UNIVERSITY OF PITTSBURGH

Performance of a unimanual motor task results in functional changes in both primary motor cortices (M1s). The neuronal mechanisms controlling the corticospinal output originating in the M1 ipsilateral to a moving arm remain poorly understood (1). Gaining insight into these mechanisms may contribute to a better understanding of how unimanual and bimanual movements are controlled (2,3,4,5).

During this presentation I will review several electrophysiological markers of motor cortical function measured at rest and during different levels of unilateral and bilateral finger, wrist and elbow voluntary movements by using transcranial magnetic stimulation (TMS). These electrophysiological markers include: motor-evoked potential (MEP) recruitment curves, short-interval intracortical inhibition (SICI), interhemispheric inhibition measured by a paired-pulse TMS paradigm and by the ipsilateral cortical silent period (iSP), and the influence of interhemispheric inhibition over SICI.

Our results have shown activity-dependent changes in SICI in M1 ipsilateral, interhemispheric inhibition from M1 contralateral to M1 ipsilateral, and in the influence of interhemispheric inhibition over SICI. Differences are observed between responses evoked from distal and proximal representations in the primary motor cortex (4,5). Altogether our findings indicate that interactions between GABAergic intracortical circuits mediating SICI and interhemispheric glutamatergic projections between M1s partly contribute to control activity-dependent changes in corticospinal output in the M1 ipsilateral to a moving arm during voluntary movement by the opposite arm.

MECHANISMS OF CHANGES IN EXCITABILITY OF THE PRIMARY MOTOR CORTEX DURING UNILATERAL MUSCLE CONTRACTIONS: IMPLICATIONS FOR CROSS EDUCATION

HORTOBÁGYI, T., HOWATSON, G., RIDER, P., SOLNIK, S., DEVITA, P.

EAST CAROLINA UNIVERSITY

There is strong evidence suggesting that unilateral exercise increases motor function not only in the muscles of the exercised limb but also in the homologous unexercised muscles of the contralateral limb, producing the phenomenon of cross education (10, 13). Such adaptations occur under a variety of conditions, including exercise with voluntary isometric, concentric, eccentric, and electrical stimulation-evoked contractions (2, 4, 8, 11). The mechanisms of these adaptations are unknown but most likely reside in the nervous system and not in the contralateral muscle itself (1, 3). The purpose of this presentation is to examine candidate mechanisms of cross education in the motor cortex and spinal cord. One possible mechanism is that neural drive in the "uninvolved" motor cortex increases due to its repeated activation during unilateral muscle contractions (7, 12, 14). The magnitude and specificity of cross education are probably related to the magnitude of activation of the ipsilateral motor cortex, which was shown to increase with intensity (7, 9, 12) and vary by type (shortening vs lengthening) (5) of contralateral muscle contraction as determined by magnetic brain stimulation. Another possibility is that chronic exercise reduces interhemispheric inhibition and the increased cross-hemispheric flow in turn increases the excitability of the uninvolved motor cortex (6). Finally, spinal mechanisms cannot be excluded but evidence for cross-segmental effects appears weak or our methods are inadequate to detect such effects (7, 9). In conclusion one of several independent mechanisms or perhaps a combination of these may mediate increased motor output in the unexercised muscles of the contralateral limb after chronic unilateral exercise. After identifying the exact mechanisms of cross education the next step is to determine if it is an effective method for the rehabilitation of unilateral movement impairments in patients with a stroke or unilateral orthopedic injuries.

NEW PERSPECTIVES ON CROSS EDUCATION: IS THERE A POTENTIAL BENEFIT OF UNILATERAL TRAINING DURING RECOVERY FROM UNILATERAL SPORTS INJURIES?

FARTHING, J.P.

UNIVERSITY OF SASKATCHEWAN

Cross education is the strength increase observed in the untrained contralateral limb after a period of unilateral strength training. Although cross education was first documented over a century ago, there is still much to learn regarding the precise neural mechanisms that control the effect and the potential utility of it during recovery from unilateral injury (1,5). Cross education is evident after a variety of unilateral training regimens with an average magnitude of 8% or about half of the strength gain observed in the trained limb (1,8). However the effect varies immensely, ranging from no significant effect up to 77% after voluntary training (6,11). There is now evidence that cross education is asymmetrical, where dominant arm training elicits much greater cross education than non-dominant training in right-handed individuals (2). This suggests that there is a preferential dominant to non-dominant direction of strength transfer in the upper limbs, which might explain some of the variation in the literature regarding the magnitude of effect. This asymmetrical transfer of strength is similar to what has been shown for cross education of skills and suggests involvement of higher order motor learning mechanisms (1,2,7). A follow-up functional MRI study provided initial evidence of changes in brain activation patterns associated with the untrained left limb, particularly in sensorimotor cortex and temporal lobe (3). While several studies have aimed to reveal mechanisms, there are few attempts to apply cross education in a rehabilitation setting (9, 10). The purpose of this presentation is to discuss the potential for cross education to be used as a strategy during rehabilitation from unilateral injuries (particularly those requiring immobilization) and to discuss the implications of asymmetry of cross education in this context. A recent study demonstrated that unilateral strength training was effective for preserving strength in an opposite immobilized limb (4). These findings suggest that there might be a therapeutic benefit of cross education during recovery from unilateral sport injuries or in other clinical settings that involve unilateral immobilization.

AGING AND RESISTANCE TRAINING INDUCED INCREASE IN MUSCLE SIZE

HULMI, J.J., SALMIJÄRVI, H., KATAJAVUORI, M., AHTIAINEN, J.P., HOLVIALA, J., SELÄNNE, H., KOVANEN, V., HÄKKINEN, K., MERO, A.A.

UNIVERSITY OF JYVÄSKYLÄ

Introduction: Resistance training (RT) increases muscle size but aging may (5) or may not (1) decrease this response. The present study investigated muscle hypertrophy and gene expression adaptations to heavy RT in young and old healthy men.

Methods

Twenty-one previously untrained young men (26.0+-4.3 yrs) and 18 older men (61.2+-4.1) participated in a 21-week RT period, comprising whole-body exercises twice a week. The training loads increased from 60 to 85% of 1RM, and the number of repetitions in each set decreased from 15-20 to 5-6 during RT. Nineteen men (42.5+-20.0) served as controls (no RT). Vastus lateralis (VL) muscle fiber cross-sectional area (CSA), expression of muscle hypertrophy regulating genes (by Real-Time RT-PCR), and muscle force were analysed before and after the 21-week period. Muscle biopsies were obtained 4-6 days after the last RT workout. Macronutrient intake was not controlled but it was registered by 4-day diaries at weeks 0, 10.5 and 21.

Results: RT led to 1.2-1.4 -fold increases in strength of leg extensors and muscle fiber CSA ($P<0.05$). Concentric leg extension 1RM increased similarly in young and old whereas isometric leg extension force increased more in young men ($P<0.05$). Type-I and mean (type I+II) muscle fiber CSA increased two times more in young men ($P<0.05$). Young men habitually ingested 1.3-1.4 times more energy and protein per body mass during RT than old men ($P<0.05$). Basal mRNA response to RT of activin receptor IIb, FLRG, MyoD, myogenin, p21, cdk2 and MAFbx were not different between young and old. However, myostatin and myogenin mRNA increased in old compared to young men ($P<0.05$).

Discussion: Larger muscle hypertrophy took place after RT in the young men. The present twice weekly heavy whole body RT may have been too demanding for some previously untrained older individuals. This may have been associated with relatively lower energy and protein intake observed in the old men. Protein and energy undernutrition among the elderly is common (3) and may be especially problematic with RT that increases need for dietary protein (4). On the other hand, it is also possible that the adaptation capacity to RT simply decreases with increasing age. It can be speculated that the increase in muscle myostatin gene expression in the old compared to the young could be related to the observed smaller muscle hypertrophy in the old, as myostatin is a negative regulator of muscle size (2).

In conclusion, aging decreased the enlargement of muscle size during 21 weeks of training. This may be explained by smaller protein and energy ingestion or by an increase in myostatin gene expression in the old.

ENDURANCE TRAINING FAILED TO STIMULATE MITOCHONDRIAL BIOGENESIS IN AGED RAT SKELETAL MUSCLE

DERBRÉ, F., GOMEZ-CABRERA, M.C., DOMENECH, E., NASCIMENTO, A.L., MARTINEZ-BELLO, V.E., SANCHIS-GOMAR, F., DE-LAMARCHE, P., GRATAS-DELAMARCHE, A., VINA, J.

LABORATORY MOVEMENT, SPORT, HEALTH (RENNES) / LABORATORY FRAG (VALENCIA)

BACKGROUND: During aging, skeletal muscle undergoes sarcopenia, a condition characterized by a loss of muscle cell mass and alterations in contractile function. The origin of these decrements is unknown, but evidence suggests that they can be partly attributed to a decrease in the mitochondrial bioenergetic capability. It is well known that endurance training up-regulates mitochondrial biogenesis pathway in young skeletal muscles. By stimulating this pathway, endurance training could also constitute a possibility to prevent the decrease of mitochondrial energy production in aged skeletal muscles.

OBJECTIVE: This study was designed to determine the effect of endurance training on the mitochondrial biogenesis pathway in skeletal muscle of aged rats.

DESIGN: 24 young (5 months) and aged (22 months) male Wistar rats were exercised for 3 weeks following endurance training. The intensity of the training was set at 75% VO2max. Expression analyses were realized in soleus (fiber type I) and gastrocnemius (intermediate fiber type) muscles.

RESULTS: Expression of key transcription factors involved in mitochondrial biogenesis (PGC-1α, NRF-1) and of cytochrome c (a marker of mitochondrial content) increased significantly in response to training in young rat soleus muscle but remained unchanged in aged rats. Aging is associated with a decrease of protein content of cytochrome c oxidase subunit II (COX II) and an increase of mitochondrial transcription factor A (TFAM) in soleus muscle suggesting a mitochondrial dysfunction. Endurance training didn't modify COX II and TFAM in both young and aged rats. Neither age nor training altered all theses protein expressions in gastrocnemius muscle.

CONCLUSION: Our study confirmed that fiber type I muscle appears more affected by age-related mitochondrial alterations than intermediate fiber type muscle (Pesce et al. 2005). Short-term endurance training failed to stimulate mitochondrial biogenesis and to reduce mitochondrial dysfunction in skeletal muscle of aged rats. This incapacity to stimulate mitochondrial biogenesis could result from age-related decrease of AMP kinase activity in skeletal muscle (Reznick et al. 2007).

CARDIAC STEM CELL ACTIVATION AND ENSUING MYOGENESIS AND ANGIOGENESIS CONTRIBUTE IN CARDIAC ADAPTATION TO INTENSITY-CONTROLLED EXERCISE TRAINING.

WARING, C., TORELLA, D., ELLISON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

Traditionally, it was thought that exercise improved cardiac function by increasing myocardial mass and contractility through physiological hypertrophy of existing myocytes and enhanced coronary perfusion. Recent data on myocardial cell homeostasis and the identification of cardiac stem cells (CSCs), in the adult mammalian heart, could challenge this concept. We sought to assess if CSC activation and ensuing myocyte and capillary formation participates in cardiac remodeling induced by intensity-controlled exercise training. To this aim, 42 male Wistar rats (226.5±1.5g) were exercised at either a Low (LI; 55-60% VO2 max) or High (HI; 85-90% VO2 max) intensity for 30 mins/day, 4 days/week for up to 4 weeks on motorized treadmills. Fifteen untrained rats acted as age-matched sedentary controls (CTRL). To track myocardial proliferation, BrdU was administered (i.p.) twice daily. Hearts were arrested in diastole and the Left Ventricles (LV) were processed for immunohistochemistry and confocal microscopy analysis. Results showed an increase ($P<0.05$) in average myocyte diameter in the LV following both LI and HI exercise training, compared to CTRL. The distribution of myocytes sizes showed the presence of both larger (hypertrophied) and smaller myocytes (myogenesis) in the ventricular wall of the exercise trained vs. CTRL hearts. Indeed, there was a significant ($P<0.05$) increase in the % of small myocytes that were BrdU (3.4±0.2 LI, 7.4±0.3 HI) and Ki67 positive (0.8±0.1 LI, 1.0±0.1 HI), following LI and HI exercise training, compared to CTRL (BrdU, 0.01±0.01; Ki67 0.05±0.02). These data document the presence of small newly formed myocytes in the LV of intensity-controlled exercising rats. The number of capillaries in the LV in the LI (2709.8±103.5) and HI (4109.5±347.7) exercise trained animals was significantly ($P<0.05$) greater than CTRL (1531.6±99.5). Many of these capillaries were BrdU positive exhibiting their recent formation. To address the source of new myocytes and capillaries, we evaluated c-kit positive (c-kitpos) CSC myocardial activation. The number of c-kitpos CSCs significantly ($P<0.05$) increased in the ventricular wall of the Exercising vs. CTRL rats. Many CSCs were proliferating (BrdU and/or Ki-67 positive) and many expressed the cardiac transcription factor, Nkx2.5, representing myocyte progenitor cells. Also, some CSCs expressed the transcription factor Ets-1, indicative of their differentiation into the endothelial lineage. These data provide a link between a primitive c-kitpos CSC and amplifying myocyte and endothelial progenitors. In conclusion, intensity-controlled treadmill exercise training in adult rats results in myocardial mass remodeling through myocyte hypertrophy, and new myocyte and capillary formation. The latter is due to the activation and ensuing differentiation of CSCs into newly-formed myocytes and capillaries. Finally, these effects were dependent on exercise training intensity.

THE EFFECT OF HIGH INTENSITY RUNNING ON INFLAMMATION, IRON STATUS AND HEPCIDIN ACTIVITY IN MODERATELY TRAINED ENDURANCE ATHLETES.

PEELING, P., DAWSON, B., SWINKELS, D., TRINDER, D.

THE UNIVERSITY OF WESTERN AUSTRALIA

Hepcidin is a liver produced hormone that acts to internalise and degrade the iron transport channels in the intestine and on the cell surface of macrophages, ultimately reducing the absorption and transport of iron in the body. Hepcidin expression is controlled by the level of circulating IL-6 and the current iron status of the body. To date, it is unknown as to the effect of high intensity exercise on the activity of this hormone within 24 h of recovery. As such, this investigation examined effect of high intensity running on inflammatory markers, iron status, and urinary hepcidin activity in male and female athletes at 3 and 24 h post-exercise.

Eleven moderately trained runners (6 male and 5 female) participated in three laboratory testing sessions including: (1) A graded-exercise test to determine maximal oxygen consumption (VO2max) and peak heart rate (HRpeak). (2) A 60-min trial of running (RUN) involving 15 min at 75-80% HRpeak and 45 min at 85-90% HRpeak. (3) A 60-min trial of seated rest (REST). The RUN and REST trials were applied in a randomised, counterbalanced order, and were separated by a minimum of 28 days, ensuring all female participants were in the follicular phase of the menstrual cycle.

Throughout the RUN and REST trials, venous blood and urine samples were collected pre-trial, immediately post-trial, and at 3 and 24 h post-trial. Blood samples were analysed for circulating levels of Interleukin-6 (IL-6), C-Reactive Protein (CRP), serum iron and serum ferritin. Urine samples were analysed for urinary hepcidin concentration. A repeated measures ANOVA for time, trial and time*trial effects was conducted between the RUN and REST trials, with post-hoc, paired samples t-tests applied in the event of a significant main effect. The alpha level was accepted at $p<0.05$.

Blood analysis revealed that three participants were classified as iron deficient, and were therefore removed from the analysis. For the remaining eight healthy iron status subjects, the immediate post-RUN levels of IL-6 and 24 h post-RUN levels of CRP were significantly increased from baseline, and when compared to REST ($p<0.05$). Hepcidin levels in the RUN trial after 3 and 24 h of recovery were significantly greater than the pre- and immediate post-RUN levels, and also when compared to the 3 h time point of REST ($p<0.05$). Serum iron was significantly increased post-RUN from baseline ($p<0.05$), but had returned to normal by 3 h of recovery. There were no significant changes in serum ferritin levels.

This study has shown that urinary hepcidin levels are significantly elevated post-exercise in moderately trained athletes with a healthy iron status. Here, elevated hepcidin activity occurred approximately 3 h subsequent to an increase in IL-6 and serum iron. As such, it is possible that the post-exercise activity of this hormone is driven by inflammation and hemolysis.

A ROLE FOR SATELLITE CELLS IN THE ETIOLOGY AND TREATMENT OF SARCOPENIA?

VERDIJK, L.B., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY

Satellite cells (SC) are the only source for the generation of new myonuclei in skeletal muscle tissue. As such, SC play a key role in muscle fiber atrophy and/or hypertrophy. We suggest that SC represent an important factor in the etiology and treatment of the age-related decline in muscle mass and strength, or sarcopenia.

Sarcopenia is characterized by the loss of type I and II muscle fibers, and specific type II muscle fiber atrophy. In accordance, recent data from our lab show that type II muscle fiber atrophy is accompanied by a specific reduction in type II muscle fiber SC content in elderly versus young males. However, it remains to be elucidated whether muscle fiber characteristics are predictive of the actual amount of skeletal muscle mass and strength in the elderly. Therefore, we correlated various skeletal muscle fiber characteristics (from muscle biopsies) with muscle mass (CT) and strength (1RM) within a population of 41 healthy, elderly males (>65y). Greater muscle fiber cross-sectional area (CSA) was associated with more myonuclei and more SC per muscle fiber (0.50≤r≤0.56 for type I and II

fibers). The number of myonuclei per fiber correlated with the number of SC per muscle fiber (r=0.40 for type I and II fibers). Furthermore, type I and II muscle fiber CSA correlated with leg muscle strength, and with quadriceps CSA. These data imply that muscle fiber size is predictive of muscle mass and strength. Furthermore, SC content is closely related to myonuclear content and is predictive of muscle fiber size. The latter provides further support to the idea that SC content is a key regulator of muscle fiber size and, as such, muscle mass and strength. Thus, to enable a substantial increase in muscle mass and strength, it seems imperative to effectively increase SC content. The latter was achieved following 3 months of resistance type exercise training in 13 healthy, elderly males. Substantial improvements in muscle mass, strength, and type II muscle fiber size were accompanied by a type II muscle fiber specific increase in SC content.

Collectively, our findings suggest that the muscle fiber type-specific decline in SC content represents a key factor in the gradual loss of muscle mass and strength with aging. The latter can, at least partly, be reversed by resistance type exercise training. Future studies should focus on optimizing SC activation, proliferation, and differentiation. The latter will be instrumental to define more effective exercise, nutritional, and/or pharmacological interventions to counteract the loss of muscle mass and function with aging.

INFLUENCE OF ACE I/D AND ACTN3 R/X POLYMORPHISMS ON MUSCLE FUNCTION AND BODY COMPOSITION OF OLDER CAUCASIAN MEN

MCCAULEY, T., FOLLAND, J.P., MASTANA, S.S.

LOUGHBOROUGH UNIVERSITY

Advancing age is associated with a progressive decline in muscle strength and function largely due to sarcopenia. Healthy older individuals have age related deficits in muscle power that are even greater than muscle strength (1) leading to compromised mobility and an increased risk of falls. ACE I/D and ACTN3 R/X polymorphisms have been suggested to influence variations in skeletal muscle function (2,3) and body composition (4). ACTN3 has been proposed as a metabolically thrifty gene thought to improve energetic efficiency (5), promote energy storage and fat accumulation. This study investigated the influence of ACE and ACTN3 genotypes on body composition and muscle function phenotypes in older Caucasian men.

Following ethical approval a range of muscle function measurements were taken from 100 healthy non strength trained UK males (60-70yrs) on two occasions. A conventional strength testing chair was used to measure maximal isometric knee extensor and elbow flexor strength. Maximum twitches were electrically evoked (Digitimer DS7AH, UK) in the quadriceps to assess time to peak tension (TPT) and half relaxation time (HRT). Isokinetic knee extensor peak torque was measured at three velocities (0, 30 and 240°.s-1) using isokinetic dynamometry (Cybex Norm, USA). Relative strength at high velocity (240°.s-1:30°.s-1) was calculated. A Dual-energy X-ray Absorptiometry (DXA) scan (Lunar Prodigy Advance DXA machine, GE Lunar, Madison, WI) was used to assess non-skeletal lean mass and fat mass. ACE I/D and ACTN3 R/X genotype were determined from whole blood samples using polymerase chain reaction, and serum ACE using spectrophotometry.

ACE and ACTN3 genotype distributions were in Hardy Weinberg Equilibrium (II 25, ID 48, DD 27; RR 43, RX 41, XX 16). Physical characteristics were independent of ACE genotype (height, body mass, lean body mass, body mass index). ACTN3 XX genotype individuals had a higher fat mass (P = 0.04), and a trend for greater body mass (P=0.09) than RR individuals. The muscle function phenotypes assessed were found to be independent of ACE and ACTN3 genotypes. Serum ACE activity was negatively correlated with the relative torque at high velocity (R =-0.23; P =0.03). There were trends for serum ACE to correlate with quadriceps (R=0.19; P=0.07) and elbow flexor (R=0.20; P=0.06) isometric strength.

ACE ID and ACTN3 RX polymorphisms did not influence muscle function phenotypes in this cohort. Serum ACE activity appeared to have a small effect on muscle function. The association of ACTN3 genotype with fat mass suggests that this polymorphism affects the accumulation of body fat over the life span of Caucasian men.

VISMO - A PROTOTYPE SOFTWARE SOLUTION FOR INTEGRATION OF VESTIBULAR, OCULOMOTOR, SPINALMOTOR AND 3D-KINEMETRIC DATA IN SPORTS

VON LAßBERG, C., REIMANN, M., KRUG, J.

UNIVERSITY OF LEIPZIG

Introduction: There are few studies concerning the relationship between vestibular load and oculomotor and spinalmotor activation during complex sport specific movements. Up to now no commercial software tool has been able to fulfil the combined exposure of kinematic, electromyographic and oculomotor signals in the field of sports. The development of the multimodal prototype software tool "VISMO" tries to close this gap to enable a better understanding of oculomotor, neuromuscular and kinematic interaction and their consequences for motor learning and technomotor modelling in sports. The aim of this publication is to present the functions of this tool.

Methods and Results: The measurement components consist of 3D-Video-kinemetry or a Vicon system, telemetric electromyography (Noraxon) and a videonystagmography system (Interacoustics) combined with a prototype of a sport specific videonystagmography goggle. The software is able to integrate these components, to calibrate and synchronize the data and to calculate a frame based 6-field view of various multifunction graphic tools and data plots. The software itself (developed by von Laßberg, C. & Reimann, M., 2008) presents 6 onscreen windows for simultaneous view or for presentation in various combinations of the windows.

The windows show a virtual athlete based on a 15 segment lattice model in virtual space. The virtual room can be exactly adapted to the real dimensions of the athlete's environment. Gaze lines and gaze spots are integrated into the virtual space. The spots represent the resulting coordinates, calculated by the head related eye data and the heads position in space. The diameter of the spots correlates with the visual fixation time on theese gaze spots. Occulomotor gain of nystagmus can also be calculated. In the model, all muscles being registered by the EMG are depicted using coloured matrices. The higher the activation level, the darker the colour with which they are visualized. Onset threshold can be defined for all muscles separately. The virtual model and room can be zoomed or moved along and around all axes. Vectors of vestibular load can be visualized within the head-model, separately. Optionally the subjective visual view of the athlete in the virtual room can be visualised and screened in helmet mounted displays for the use in further research concerning visuo-mental training methods. All data plots calculated by the software are visualized synchroneously in a separate window: The plots can be selected as required and be exported to other programs (e.g. for further statistical analysis).

Conclusion

To better understand the complexity of human movement, it is necessary to have a deeper insight into human control processes. The benefit of this software is the ability to combine the extrinsic view with intrinsic data of movement control to better understand their relationships in sports and daily life.

A SIMULATOR FOR RACE-BIKE TRAINING ON REAL TRACKS

DAHMEN, T., SAUPE, D.

UNIVERSITY OF KONSTANZ

We develop methods for data acquisition, analysis, modeling and visualization of performance parameters in endurance sports with emphasis on competitive cycling. For this purpose, we designed a simulator to facilitate the measurement of training parameters in a laboratory environment, to familiarize cyclists with unknown tracks, and to develop models for training control and performance prediction.

The simulator is based on a Cyclus2 ergometer (RBM Elektronik-Automation GmbH, Leipzig, Germany), which provides a realistic cycling experience since one can mount arbitrary bikes and its elastic suspension even allows for a sway pedal stroke. The eddy current brake guarantees non-slipping transmission of a braking resistance up to 3000 W.

Operating the Cyclus2 in the gradient mode, we impose arbitrary slopes by our own platform independent PC-based control software at a sampling rate of 2 Hz. The height profiles for various tracks were recorded using a commercial GPS device.

The Cyclus2 has two major constraints with respect to simulating real tracks: We must focus on tracks without downhill accelerations since it has no engine and the eddy current brake requires a minimum rotation velocity of the flywheel to accurately generate the brake force. Therefore, we fixed the derailleurs to a heavy gear and mounted four electronic buttons to the handlebar which act like shift levers of virtual gears. Our software incorporates the virtual gear into the gradient so that the cyclist feels a correct resistance while the flywheel exceeds the minimum rotation velocity in all realistic uphill scenarios. Moreover, we can simulate arbitrary gears easily and record them over time. As the physical flywheel rotation is faster than in the simulation, our software must correct the related performance data.

The simulation includes a video playback that is synchronized with the cyclist's current position on the track. In addition, time, distance, speed, cadence, heart rate, power and gears are monitored, a 2D-projection of the course gives feedback on the progress and a gradient profile indicates the slope in the surrounding of the current position.

Comparative outdoor tests with an SRM power meter (Schoberer Rad Messtechnik, Welldorf, Germany) show that the simulator gives reasonable estimates for different pacing strategies (constant power/speed/heart rate).

In future, we strive to integrate a more precise mechanical model (Martin et al., 1998), extend the palette of physiological measurements (oxygen consumption, ECG, lactate etc) and implement models for these parameters. The whole system shall indicate the optimum pacing strategy as Gordon derived in 2005 for simple models and synthetic data. Using sophisticated biofeedback visualization, cyclists shall be able to optimally prepare themselves even for unfamiliar tracks on our simulator.

ANALYZING THE AIMING PROCESS IN BIATHLON SHOOTING USING SELF-ORGANIZING MAPS

BACA, A., PERL, J., KORNFEIND, P., BÖCSKÖR, M.

1. UNIVERSITY OF VIENNA, 2. UNIVERSITY OF MAINZ

Introduction: The aiming strategy in biathlon shooting is a crucial factor for success. Because of the preceding high exertions of the athletes a well controlled motion of the barrel just before shooting is essential (Zatsiorsky and Aktov, 1990). Methods are required for analyzing the stability of the aiming process with a special focus on exertion. The aim of this study was to investigate the applicability of special self-organizing maps to identify and compare patterns in the aiming motion in standing shooting.

Methods: A video based system (Baca and Kornfeind, 2006) was used to track the motion of the muzzle of the barrel in two dimensions (left-right, up-down) automatically. Six parameters were calculated describing the motion in ten time intervals of 0.2 s length before the shot. Four athletes (I, II, III, IV) (I, III, IV: Austrian national "B" team, II: "C" team) participated in the study. Each athlete performed four series of five shots before and after exertion making 160 shots altogether.

Based on these data a special self organizing map (Perl et al., 2006) consisting of 400 neurons was trained and data sets were generated on the neurons. The attribute values of those data sets represent the six components describing a motion of a muzzle in a 0.2 s time interval. Similar neurons were combined to clusters.

The ten successive data-sets describing each shot were then mapped to the corresponding neurons of the net. The sequence of the related clusters in the respective succession was then used as 1-dimensional representation (a pattern) of the complex aiming motion.

Results: Regarding intra-individual stability, some peculiarities were found. The number of a shot within a series of five shots clearly influenced the pattern observed. This was particularly the case after exertion. Moreover, in this condition less stable shot types were found. Subjects were able to maintain their pattern before the exertion to a different degree. Subject II, who showed the largest deviations, scored worst.

Although inter-individual variability was difficult to assess, some similarities (e.g. in timing) could be identified.

Discussion: The method is promising to analyze inter- and inter-individual similarities and differences. One shortfall might be that only a restricted set of parameter values originating from a 2-dimensional recording of the muzzle has been considered. Time series data

describing the 3-dimensional motion of the barrel would probably increase the explanatory power. In addition, alternatives not based of a fixed time interval for analysis (2 seconds before the shot) are conceivable.

ANALYSIS OF SEQUENTIAL BEACH VOLLEYBALL ACTIONS

KOCH, C., TILP, M.

KARL-FRANZENS UNIVERSITY

Introduction: In recent years experts have criticized the analysis of single actions in sports games (Carling et al., 2005). Simple tally counts of observed single actions do not represent the process of sport games sufficiently. The missing consideration of game interactions leads to information out of context which limits useful conclusions for practitioners. Therefore, the aim of this study was to analyse the action sequences in beach volleyball by using a database with single action descriptions and subsequent specific database queries. Deduced from sports practice the following questions were of interest: How does the service technique affect the reception performance? How does the setting quality affect the attack performance? Do men and women perform similar?

Methods: The basis of action sequence analysis is a systematic notational analysis of single actions out of video recordings. The behaviour of male and female world league players (29 matches during a world tour tournament) was described and registered with the game analysis software "Statshot" concerning technique, quality, location of action, direction and type of movement (Tilp et al., 2006). During the analysis the collected actions (approx. 16000) were classified regarding their affiliation to rallies and their temporal position during the rallies. Subsequently, database queries allowed the analysis of actions sequences. Chi-square tests were used to test statistical significance ($p<0.05$).

Results: The relationship between service technique and reception performance was observed to be gender specific. Female athletes received 44% of all float serves without a jump in poor (low ball trajectory or imprecise) or bad (mistake) quality (men: 30%). In contrast, 39% of all jump serves received by male athletes were of weak quality (women: 37%). Gender differences could also be detected in the relationship between setting quality and attacking technique. While men and women used the same distribution of the two attacking techniques (smash and shot) following excellent and poor setting actions, a different behaviour could be observed following setting actions of medium quality. While women played much more shots (72%) than smashes (28%), men used both techniques equally. All mentioned differences were statistically significant.

Discussion: The presented and additional results indicate that the analysis of sequential beach volleyball actions allows more specific conclusions in the game context than the analysis of single actions. It is possible to gain new and useful results for structure- and team analysis. Further research should reveal if stereotypic behaviour of teams can be identified with this method.

BEIJING IN PERSPECTIVE

STEFANI, R.

CALIFORNIA STATE UNIVERSITY, LONG BEACH, USA

The 2008 Beijing Olympic competition is into historical perspective. China's 100 medals represent an increase by the host nation of 59% over the 63 medals won four years earlier. This is superior to the 44% average home-nation advantage for the 11 most recent fully-attended Games.

In spite of the remarkable Usain Bolt, only 50% of 34 comparable athletics winning performances at Beijing were better than at Seoul in 1988, an improvement over 44% for the 2004 Olympics vs. Seoul and 32% for the 2000 Olympics. Following the 1988 Olympics in which Ben Johnson (Canada) was disqualified in the 100 m run, due to a doping violation and a Canadian government report concluding rampant doping in athletics and weightlifting, international anti-doing measures were significantly increased. The World Anti-Doping Agency website indicates that the downturn in some athletics performances in the 1990s were due to those anti-doping measures. It is a hopeful sign that the number of adverse finding dropped from 26 in the 2004 Olympics to 6 at Beijing. It appears that the more-or-less drug free performances of 2008 are at about the level of the drug-enhanced performances of 1988. Cumulative improvement is charted for Olympic winning athletics performances from 1924-2008. The influences of WW2, the cold war, boycotting and drug-enforcement are clear.

By the end of the Beijing Olympics, Michael Phelps had set 32 world records while Mark Spitz (USA) had set 33. Johnny Weissmuller (USA), a swimmer from the 1920s, set 67 world records (more than Phelps and Spitz combined) and was undefeated in competition, arguably making Weissmuller the best of all time. The improvement in winning swimming times by 1.8% over those in 2004 represents more of a return to past levels of improvement than breaking any new ground. It is noted that 3 m deep pools were used in 2004 (Olympics) and 2005 (FINA worlds) without an avalanche of world records but 3 m pools in 2007 (FINA worlds) and 2008 did have many world records. It is suggested that the maturing of swimmers who were enticed to enter serious swimming competition at the time of the 1996 and 2000 Olympics is the reason for current improvements.

The drag of a swim suit is measured passively in a smooth fluid flow environment while competitive swimming provides much more turbulence. It is estimated that actual drag reduction in competition is less than 1%. The cumulative improvement in Olympic swimming winning performances is charted from 1924 to the present. The affects of WW2, the cold war and boycotting are clear. One downturn is discussed for 1996 when drug testing was expanded. Swimming improvement has been steadier than in athletics. Greater improvement is noted for swimming, jumping and throwing (leverage events) than for running events.

XIII PARALYMPIC GAMES 2008 IN BEIJING: THE ANALYSIS OF RESULTS: BARYAEV, A., SHELKOV, O., EVSEEV, S.

ST PETERSBURG RESEARCH INSTITUTE OF PHYSICAL CULTURE

Introduction. Paralympic games are the second on social importance-after Olympic games-world sports event. The attention to them from world community increases every year. The quantity of participants on this sports forum constantly grows. So, if on Paralympic games in Rome (1960) 400 athletes have taken part that on last games in Beijing there were already 4017 athletes.

Methods. Employees of the St.-Petersburg research institute of physical culture accept active participation in scientifically-methodical maintenance of Russian paralympic national teams. In article presented the analysis and comparison of statistical data received following the XIII Paralympic games 2008 in Beijing results and participations in it Russian national team.

Results. Total of the world records established in Beijing-298 (136-swimming, 115-track and field athletics, 7-shooting, 8-archery, 10-powerlifting). The considerable superiority on these indicators the national team of China, more than in 2 times outstripped Ukraine, USA, Great Britain. What achievements of the countries-leaders in Paralympic movement? We made results comparison of 15 leading teams on last 3 games. The most important changes in the program of competitions: inclusion in it rowing, and also reduction of medals sets for 10 percent in comparison with Athens. In 2008 only 7 teams have kept the first 10 places in comparison with previous (China, Great Britain, USA, Ukraine, Australia, Canada and Spain). The greatest progress from 2004 for 2008 reached South Africa, Russia, Ukraine, Brazil, Tunisia and Korea. For definition of the reasons and conditions of successful performance we have compared team ranks on gold medals, the sum of medals and quantity of participants. It has turned out, that team's occupied first 3 places in the general table; include about 200 athletes (China-332), Great Britain and USA (on 209 in everyone). It is necessary to notice, that two teams: Ukraine (124) and South Africa (61) achieve high sports results with a small amount of participants. In this context it is interesting to consider quantity of the athletes who have won more than one medal (multimedallists). The obtained data show that fact, which South Africa has successfully acted at the expense of five 'gold' multimedallists who have won 15 gold awards, the made 71 % from number of all gold medals won by athletes of this country.

Discussion. The received results allow ascertaining, that in paralympic training process, all takes root into designing and creation of means a science more actively. Special interest represents increase in the importance of multimedallists achievements in various kinds of sports. The increase in quantity of the countries and the athletes who are taking part in paralympic games, expansion of 'geography' of medal winners say that the focused humanistic concept of the states relation more and more clearly admits the world community and a society to disabled persons.

OP-NU01 Nutrition 1

EFFECT OF BETA-ALANINE SUPPLEMENTATION ON SUSTAINED ISOMETRIC MUSCLE CONTRACTIONS IS INTENSITY-DEPENDENT

WILLEMS, M., PONTE, J., HARRIS, R.

UNIVERSITY OF CHICHESTER

Introduction: The dipeptide carnosine (β-alanyl-L-histidine) acts as an intramuscular proton buffer. Beta-alanine supplementation increased muscle carnosine content and high intensity cycling performance (Hill et al., 2007) potentially by postponing muscle fatigue. It is unknown whether the performance enhancing effect of β-alanine supplementation is intensity dependent. Therefore, the purpose of this study was to examine the performance of sustained isometric contractions of the quadriceps femoris muscles at two different intensities.

Methods: 24 physically active subjects (3 females, 21 males, 20±3 years; 76.6±11.3kg; 1.77± 0.08m) participated in a placebo-controlled triple-blind study. Subject's upper body was restrained and hip and knee joint angles were kept at 90°. Subject's ankle of the non-dominant leg was connected to a force transducer (sampling frequency 1000Hz). In two sessions, maximal voluntary isometric force (MVIF), time to task failure during 20%MVIF and 70%MVIF and MVIF 20 seconds after task failure, for calculation of fatigue index, were measured before and after supplementation. Post-supplementation testing of 20%MVIF and 70%MVIF was performed at pre-supplementation MVIF values. Subjects were supplemented with 6.4g/day of beta-alanine (n=11) (8 x 2 capsules, Carnosyn™, NAI, San Marcos, CA) (Harris et al., 2006) or placebo (n=13) (8 x 2 capsules Maltodextrin) (supplementation period 38±7 days). Two-way ANOVA with post-hoc paired samples t-tests were used for data analysis with significance level set at $P < 0.05$.

Results: In both groups, there was no change in MVIF after supplementation. Both groups increased the time to task failure during 20%MVIF by 12-16%. The increase in time to task failure during the 20%MVIF in the placebo group was associated with an increase in the fatigue index (pre: 31.6±10.5%; post: 39.7±14.7%). No change in fatigue index occurred following a 20%MVIF after beta-alanine supplementation (pre: 42.9±20.3%; post: 47.5±20.3%). For the 70%MVIF, there was a significant 30% increase in time to task failure (pre: 42.4±11.9s, post 55.0±21.0s) with no change in the placebo group (pre: 43.1±9.2s, post 47.3±13.1s). In both groups, there was no change in fatigue index following the 70%MVIF.

Discussion: Beta-alanine supplementation in physically active individuals 1) had no effect on the force-producing capability during maximal isometric muscle contractions, 2) had no effect on the calculated muscle fatigue index following sustained isometric muscle contractions at both low and high intensities, 3) enhances muscle isometric endurance but the effect is intensity-dependent. Beta-alanine supplementation may be beneficial for performance of high-intensity exercise.

THE EFFECT OF ORAL L-ARGININE SUPPLEMENTATION ON LEG SPEED, ANAEROBIC CAPACITY AND MUSCULAR STRENGTH.

ZACHAROGIANNIS, E., PARADISIS, G., KOLIFA, M., GERAKAKI, M., SMIRNIOTOU, A., ROUSOPOULOS, V.

DEPARTMENT OF TRACK & FIELD, FACULTY OF PHYSICAL EDUCATION AND SPORTS SCIENCE, UNIVERSITY OF ATHENS, GREECE.

L-arginine is widely used by athletes as an ergogenic aid to improve physical performance for three main reasons: 1) its role in the increase of the secretion of growth hormone; 2) as a precursor for creatine synthesis and 3) its most important role as a precursor for the

biosynthesis of nitric oxide who serves as a messenger to trigger blood vessel dilation and increase blood flow. However, only little information on its real efficacy is available from controlled studies.

Purpose: We evaluated the effects of prolonged supplementation of L-arginine on 35m performance time (t35m), anaerobic capacity (AC) and leg knee extensors (PE) and flexors (PF) maximal power and explosive leg strength (ELS) using a double blind placebo-controlled trial.

Methods: Sixteen healthy sprint and endurance trained subjects nine male and seven female (27.5±8.1 years) performed: the running anaerobic speed test (RAST), knee extensors and flexors maximal power test and a vertical jump to evaluate leg explosive strength before and after intake of L-arginine (3 grams per day) or placebo for a period of three weeks.

Results: After intake of L-arginine mean ±sd (5.26±0.36 v 5.11±0.29, arginine group AG) 35m-performance time (t35) improved (decreased) 2.85% ($p<0.05$) compared with 0.35% improvement in placebo group (PG). Fatigue index AC test (% speed drop between first and sixth sprint) did not change significantly ($p>0.05$) after arginine supplementation (10.61±3.78 v 9.4±3.74) compared with PG values (11.5±5.56 v 10.15±5.89). No significant differences were also observed between groups in body composition, PE, PF or ELS.

Conclusions: L-arginine supplementation appears to influence positively sprinting ability but did not influence body composition, anaerobic capacity and leg power and strength measures.

EFFECTS OF WHEY PROTEIN SUPPLEMENTATION WITH AND WITHOUT BETA-HYDROXY-BETA-METHYLBUTYRATE <HMB> ON FAT FREE MASS AND MUSCLE STRENGTH AFTER A 12-WEEK RESISTANCE TRAINING

STAHN, A., TERBLANCHE, E.

CENTER OF SPACE MEDICINE, CHARITÉ CAMPUS BENJAMIN FRANKLIN

Introduction: Beta-hydroxy-beta-methylbutyrate (HMB) has been reported to have anti-catabolic effects, thus enhancing gains in both muscle strength and lean tissue mass during resistance training. It is less clear, however, whether HMB promotes additional benefits when combined with a sufficient protein and carbohydrate supplementation. The aim of the present study was therefore to investigate the independent effects of HMB and a protein-carbohydrate diet on fat free mass (FFM) and muscle strength after periodized 12-week whole-body resistance training.

Methods: With institutional ethics approval 16 healthy, young men (Age mean 22.1, SD = 1.6) with less than six months weight training experience were randomly assigned in a double blind fashion to either a control group or treatment group with no significant mean differences in FFM and 1-repetition maximums (1RM). In addition to 40 g of carbohydrates which were administered orally immediately following the termination of each exercise bout, both groups ingested 30 g of whey protein in the morning on nontraining days and one hour before and after each training, respectively. Additionally, the treatment group received 1 g of HMB, whereas the control group obtained a placebo three times daily. After a 2-week familiarization period subjects trained 4 times per week using an upper/lower body split routine employing exercises of 3 to 4 sets at an intensity that varied between 10RM and 6RM. Outcome measures included whole-body FFM determined by skinfold measurements, upper arm and thigh muscle cross-sectional area determined by magnetic resonance imaging and muscle strength determined by bench press and leg press.

Results and Discussion: Repeated multivariate analysis of variance (time × group) indicated a significant main effect for time ($P < 0.001$, eta2 = 0.951), but not for group ($P = 0.970$, effect size eta2=0.021). These results were confirmed by a lack of a significant interaction between time and group ($P = 0.502$, eta2=0.186). Univariate main effects for time showed that irrespectively of the group all, outcome measures significantly increased from pre to post ($P < 0.001$, eta2= 0.575 to 0.939). These findings suggest that in young healthy subjects HMB supplementation in combination with a sufficient protein-carbohydrate diet is not superior to a protein-carbohydrate diet alone.

THE EFFECTS OF A NUCLEOTIDE SUPPLEMENT (INMUNACTIVE) ON LYMPHOCITE PROLIFERATION AFTER INTENSIVE EXERCISE

CASAJÚS, J., MARTÍNEZ-PUIG, D., SÁNCHEZ, D., AGUILÓ, J., ANEL, A., LOU, J., CHETRIT, C.

BIOIBERICA S.A.

(3) Dpto. Farmacología y Fisiología. FCCSYD Universidad de Zaragoza. Huesca (Spain)

(4) Dpto. Fisiatría y Enfermería. FCCSYD Universidad de Zaragoza. Huesca (Spain)

It has been described that intensive exercise is followed by a period of immune impairment (decreased lymphocyte proliferation and levels of salivary immunoglobulin A) during which there is an "open window" opportunity for pathogens (Petersen and Pedersen, 2002). It has been also demonstrated that dietary nucleotide supplementation is crucial to maintain immune function during stress situations (Gil, 2002). The aim of the present study was to test the impact of a specific nucleotide formulation (Inmunactive, Bioiberica, Spain) on the immune function of athletes after severe physical stress. A total of 20 athletes were recruited in a randomized double blind placebo controlled trial and distributed on 2 groups (N=10) supplemented with placebo (group C) or Inmunactive (group I) at 600mg/d during a period of 32 days. On day 0 and on day 32 each subject undertook an exhaustion exercise test using a cycloergometer at 70-80% %VO2max during at least 1h. Before and 24h after the exercise test, blood samples were taken to analyze lymphocyte proliferation of total, CD4+ and CD8+ subsets. 24h after the first exercise test, a decrease on lymphocyte proliferation was detected for both groups on total (-14.23±4.47 vs -11.52±4.93 % for groups C and I respectively; $P>0.05$), CD4+ (-6.60±5.68 vs -14.01±9.92; $P>0.05$) and CD8+ (-21.37±9.90 vs -24.60±14.08; $P>0.05$) cell subsets. At the end of the trial, after 32 days receiving the experimental product, lymphocyte proliferation 24h after the exercise test decreased on the placebo group but not in the supplemented group, in total (-3.64±4.50 vs 12.88±7.11 % for groups C and I respectively; $P=0.073$), CD4+ (-7.69±3.63 vs 15.26±5.74; $P<0.01$) and CD8+ (4.27±7.90 vs 23.58±12.49%; $P>0.05$). These results suggest that a specific nucleotide supplement given chronically may counteract the immune impairment associated to the severe physical stress.

ADMINISTRATION OF AN ANTIOXIDANT MULTI VITAMIN/MINERAL SUPPLEMENT REDUCED TRAINING INDUCED INCREASES IN VO2MAX IN WELL TRAINED SUBJECTS

SKAUG, A., SVEEN, O., RAASTAD, T.

ØSTFOLD UNIVERSITY COLLEGE, HALDEN, NORWAY, NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Antioxidant supplements are widely used by athletes on both top and recreational level. However, the notion that oxidative stress during exercise may be an important stimulus for the adaptive response to endurance training [1, 2], has questioned the value of taking antioxidant supplements in this population. Consequently, the aim of this study was to investigate the effect of an antioxidant supplement on training induced changes in VO2max in well trained subjects.

Methods: In a double-blinded placebo controlled design a total of 40 amateur soccer players were randomised into a placebo group or an antioxidant supplemented group (SUP), and 28 of the participants completed the study. The SUP group (n=13) ingested 4+4 capsules per day of a combined antioxidant and vitamin/mineral supplement (LifePak) and the placebo group (n=15) took a similar amount of capsules containing lactose. The supplementation period lasted for six weeks, and before and after the participants were tested for skin caretonid score and VO2max. During the supplementation period all subjects continued their normal training.

Results: Six week supplementation with the antioxidant vitamin/mineral supplement increased skin caretenoid score by 20±7% while no changes in skin caretenoid score was observed in the placebo group. VO2max increased by 7.5±2.2% in the placebo group while no changes was observed in the SUP group. The relative increase in VO2max was significantly higher in the placebo group than in the SUP group.

Discussion: The antioxidant vitamin/mineral supplement used in this study reduced training efficiency by blocking the training induced increase in VO2max. Although possible mechanisms behind this finding was not investigated, this result supports the idea that administration of large amounts of antioxidants may reduce the signalling activity in pathways dependent on the formation of reactive oxygen or nitrogen species.

MAGNESIUM – DIETARY INTAKE, SUPPLEMENT USE AND SERUM CONCENTRATION IN ELITE YOUNG GERMAN ATHLETES

BRAUN, H., KOEHLER, K., ACHTZEHN, S., PREDEL, G., THEVIS, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: Magnesium (Mg) plays an important role in many cellular processes. This might explain why Mg supplement use is still widespread in the athlete community (Braun et al., 2009), even though dietary magnesium intake seems adequate for most athletes. Since data for young athletes is rare, the aim of this study was to compare dietary Mg intake, Mg supplement use and serum Mg concentrations in young athletes.

Methods: Between January 2007 and October 2008, 306 athletes visited the German research centre of elite sports for a medical examination. Two hundred fifty athletes reported their dietary situation using a validated 7 d food & activity record. On the morning following the recording period fasting blood samples were taken. A questionnaire regarding the frequency of supplement use was provided in advance by mail. Complete data was available for 195 (age 16.3 ± 2.8 y, male n = 99, female n = 96) athletes.

Results: Sixty-five (33 %) athletes took magnesium as dietary supplement in the past 4 weeks before the medical examination. Mean dietary magnesium intake (without supplements) was higher in supplement users (SU: 567 ± 196 mg/day) compared to non-users (NU: 485 ± 204 mg/day) ($p < 0.01$). However, dietary Mg density was similar (SU: 206 ± 47 mg/1000 kcal; NU: 199 ± 61 mg/1000 kcal). Mean serum levels were 0.86 ± 0.07 mmol/l (SU) and 0.87 ± 0.08 mmol/l (NU) respectively. Additionally those who consumed Mg supplements on a daily basis did not have elevated serum Mg levels (n = 8; 0.87 ± 0.06 mmol/l). While energy intake was significantly correlated with Mg intake ($r = 0.68$, $p < 0.001$), we found no association between Mg intake and serum Mg ($r = 0.02$).

Discussion: In the present study, we found decreased serum magnesium concentrations only in a few cases. However, it seems that an optimal serum Mg concentration for (young) athletes has not been defined (Fogelholm 1995). Mean Mg dietary intake were above the German RDA and increased with energy intake. In agreement with others (Fogelholm et al., 1991) we found that Mg serum does not reflect dietary intake. Consistent with an earlier study (Weller et al., 1998) there were no differences in serum Mg between SU and NU. Based on the described findings it should be questioned why young athletes use Mg supplements. The benefits of those supplements seem to be lacking, while the risk of contaminated supplements should not be underestimated.

OP-SA01 Sport statistics & Analyses

A STUDY TO DETERMINE THE IMPORTANCE AND VALUE OF TAKING-A-CHARGE IN MEN'S DIVISION I COLLEGE BASKETBALL IN THE UNITED STATES

SWALGIN, K., KNJAZ, D.

PENN STATE UNIVERSITY AND THE UNIVERSITY OF ZAGREB

Introduction: The game of basketball can be defined by its structure, the rules that govern play and the value of the performance factors established for the sport. As the structure, rules, and quality of play have evolved, so have the primary statistical performance factor that quantify the quality of play that defines the game. Unfortunately, one of these defining performance categories has been left-out of the official 'box score' or record. That category is Taking-A-Charge (TC). The purpose of this study was determine the importance and value of TC's. A secondary purpose was to establish a foundation for Taking-Charges to be viewed as an important performance category that should be mandated in the official record of the game.

Method: The total population (n=342) of men's Division I college basketball coaches were surveyed to determine: 1) if they recorded TC's, 2) if they planned practice-time to teach TC's, 3) how much they emphasized TC's as part of their team defense, and 4) how strongly they felt to include TC's as a primary statistical category.

Results: Of the 342 coaches that were surveyed, 103 returned completed surveys representing 30% of the population. One or more coaches' returned surveys from each of the 29 conferences throughout the U.S. Question 1, do you record TC's as a statistic, .757 percent indicated they did. Question 2, do you plan practice-time to teach TC's, .772 percent indicated they did. Question 3, how much emphasis do you put on TC's, the results of a Likert scale indicated: 1=.009%, 2=.047%, 3=.104%, 4=.208%,and 5=.481%. Question 4, do you feel TC's should be kept as a primary statistical category, Likert scale results indicated; 1=.099%, 2=.079%, 3=.168%, 4=.208%, and 5=.446%.

Discussion: Division I coaches in the U.S. are professional coaches. The importance of TC's is illustrated from the results of Q1 and Q2 that indicate 75.7% keep TC's as a statistic, 77.2% planned practice-time to teach the skill or tactic. The results of Q3 indicate 84% of coaches' emphasized or strongly emphasized TC's as part of their team defense. When asked if TC's should be establish as a required primary statistic, 65.4% agreed or strongly agreed and 16.8% were undecided. Taking-A-Charges as indicated from the results of the survey of coaches is an important performance factor that has an established value for the game; it creates a change-in-possession leading to a scoring opportunity, and as well, takes a scoring opportunity away from the opponent. Taking-a-charge also adds to team foul totals leading to the Bonus-Free-Throw situation sooner, and results in a Personal Foul that may lead to a player's disqualification and/or reduced playing time to protect against disqualification. It is apparent form the results of the survey that coaches view Taking-A-Charges as a valued performance factor for the game and support its inclusion to the official statistical record of basketball

RATING ELITE AND NON-ELITE TENNIS PLAYERS

CLARKE, S.

SWINBURNE UNIVERSITY OF TECHNOLOGY

Unlike golf and chess, tennis suffers from having no universal objective rating system that applies from beginners to champions. Even the rating systems used in open professional tennis are non scientific, somewhat ad hoc accumulative systems that often give no credit to outstanding performances. Some of the drawbacks of these systems will be discussed, and a simple adjustive rating system shown to be more effective than the ATP tennis rating system for predicting match results of elite players. The aim of this research is to extend this system to club players. Rating players is also important at a non elite level –to the individual wishing to measure improvement or achievement, to selection committees wishing to choose between players for competition teams, to competition organizers wishing to group teams into sections of similar standard, and to national organizers for talent identification. Methods of rating non-elite players, by analyzing results from a local veterans doubles tennis competition are investigated. Depending on the level of detail in the collected statistics, the effects of position played, partner, strength of team opposition and strength of individual opponent can be taken into account. A method of extending the above adjustive rating system to rate non-elite players on a continual basis is suggested, and some preliminary results discussed.

EVALUATION OF ERRORS IN ALPINE SKIING VIDEO ANALYSIS

CHARDONNENS, J., FAVRE, J., CATTIN, S., JOLLES, B.M., GREMION, G., AMINIAN, K.

1. ECOLE POLYTECHNIQUE FÉDÉRALE DE LAUSANNE, 2. FISCHER SPORTS GMBH, 3. CENTRE HOSPITALIER UNIVERSITAIRE VAUDOIS & UNIVERSITY OF LAUSANNE

INTRODUCTION: Video records are widely used to analyze performance in alpine skiing at professional or amateur level. Parts of these analyses require the labeling of some movements (i.e. determining when specific events occur). If differences among coaches and differences for the same coach between different dates are expected, they have never been quantified. Moreover, knowing these differences is essential to determine which parameters reliable should be used. This study aimed to quantify the precision and the repeatability for alpine skiing coaches of various levels, as it is done in other fields (Koo et al, 2005).

METHODS: A software similar to commercialized products was designed to allow video analyses. 15 coaches divided into 3 groups (5 amateur coaches (G1), 5 professional instructors (G2) and 5 semi-professional coaches (G3)) were enrolled. They were asked to label 15 timing parameters (TP) according to the Swiss ski manual (Terribilini et al, 2001) for each curve. TP included phases (initiation, steering I-II), body and ski movements (e.g. rotation, weighting, extension, balance). Three video sequences sampled at 25 Hz were used and one curve per video was labeled. The first video was used to familiarize the analyzer to the software. The two other videos, corresponding to slalom and giant slalom, were considered for the analysis. G1 realized twice the analysis (A1 and A2) at different dates and TP were randomized between both analyses. Reference TP were considered as the median of G2 and G3 at A1. The precision was defined as the

RMS difference between individual TP and reference TP, whereas the repeatability was calculated as the RMS difference between individual TP at A1 and at A2.

RESULTS AND DISCUSSION: For G1, G2 and G3, a precision of +/-5.6 frames, +/-3.0 and +/-2.0 frames, was respectively obtained. These results showed that G2 was more precise than G1, and G3 more precise than G2, were in accordance with group levels. The repeatability for G1 was +/-3.1 frames. Furthermore, differences among TP precision were observed, considering G2 and G3, with largest differences of +/-5.9 frames for "body counter rotation movement in steering phase II", and of 0.8 frame for "ski unweighting in initiation phase".

CONCLUSION: This study quantified coach ability to label video in term of precision and repeatability. The best precision was obtained for G3 and was of +/-0.08s, which corresponds to +/-6.5% of the curve cycle. Regarding the repeatability, we obtained a result of +/-0.12s for G1, corresponding to +/-12% of the curve cycle. The repeatability of G2 and G3 are expected to be lower than the precision of G1 and the corresponding repeatability will be assessed soon. In conclusion, our results indicate that the labeling of video records is reliable for some TP, whereas caution is required for others.

SPACE-TIME COORDINATION DYNAMICS IN BASKETBALL: INTRA- AND INTER-COUPLINGS AMONGST PLAYER DYADS

BOURBOUSSON, J., SEVE, C., MCGARRY, T.

NANTES ATLANTIC UNIVERSITY

Introduction: Interpersonal coordination in game sports is an emerging field of interest in sport science. Indeed, formal evidence is gathering for the viability of a complex system description for some individual sports but not yet for team sports. The objective of the present study therefore was to assess basketball game behaviour within the general context of a dynamical system description.

Methods: Six game sequences from a French professional basketball game were analysed from which the x-y coordinate data of each player was obtained using a tracking procedure. The longitudinal (forward-backward movements) and lateral (side-to-side movements) patterns of each possible dyad were then subjected to relative phase analysis using the Hilbert transform. The relative phases were reported as frequency histogram data. Single instances from select dyads and game sequences were then investigated for evidences of stabilities and instabilities as well as phase transitions within a data sequence.

Results: In general the attacker-defender dyads demonstrated a strong in-phase relation (attractor of 0 degree) for the longitudinal and lateral data. In the lateral direction, however, for both teams the two wing players being teammates yielded strong attractions to anti-phase (attractor of 180 degrees), and the guard and center players demonstrated a bi-modal distribution with phase attractors of -150 degrees and 90 degrees. Discriminating the two teams, one team exhibited more distinct intra-coupling phase relations than the other. Single instances from select dyads and game sequences furthermore demonstrated evidences of phase stabilities (on 0 degree and 180 degrees) that were temporarily perturbed before the phase relation was restored. Intermittent switching was also observed in the data either between in-phase and three quarter-phase, or between the anti-phase and quarter-phase relations.

Discussion: The results demonstrated that the forward-backward movements of basketball players are much constrained by the context of the game demands. This finding was not extended to the lateral direction, however, as evidenced in the varying phase relations reported for some dyads. Similar patterns across teams were identified suggesting the presence of a common coupling within the dyads based on position considerations, a possible consequence of well established game playing habits. That said, some observed differences between the teams indicated that one team was more patterned in its behaviours whereas the other was more changeable to the game context. In sum, the findings demonstrated that the space-time patterns of basketball player dyads conform to a uniform description according to dynamical principles of self-organizing systems.

ANALYSIS OF THE USE OF THE TRAVELLING RULE IN THE EUROPEAN CHAMPIONSHIP IN BASKETBALL 2005.

FOSNÆS, O., MILLER, B., KNJAZ, D.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: All ballgames have rules that define the way the game is supposed to be played. These so called primary or constitutive rules tells us how the players are allowed to act in order to try to score or bring the ball up the court, it also tells us how the players should act against each other. The most important rules concerning this are the travelling rule and the rules allowing or forbidding contact between the players. (Fosnæs 2009)

Methods: 4 games of the European championship in Basketball in Serbia 2005 are analyzed. We are looking at every action in offense when a player receives the ball, starts a dribble, stops or make a shot. The actions are analyzed frame by frame on a screen. The actions are compared with the international rules of the game (FIBA rules). The registration will also tell what kinds of moves are made, and when there is a violation we will register the kind of mistake.

Results: In average there are in general between 100 and 160 actions in every period. 1 or 2 of these actions are called as travelling violation according to the rule by the referee. In our analysis between 22 % and 40 % of the actions are violating the rules.

Discussion: The referees do not have the same chance as we have to see the situation frame by frame, and watch it many times to study what kind of movement the players are doing. And some of these rule violations are almost impossible to observe without DVD. There are several concerns to discuss here. If a player gets an advantage violating the rule it is easy for the defensive player to be beaten or to make a foul in the next situation.

The referees will always consider the situation, and call for the mistakes that are made. Sometimes it seems as if they have a common understanding of how they are to use the rule. As Fosnæs (2009) says the travelling rule and the contact rule are the most important rules describing how the game is to be played, a more loose way of calling the travelling rule might change the game. This again will influence on the teaching and learning of basketball both in schools and in the sport outside the schools. If the rule is difficult either to live up to or to call by the referees, may be the rule itself should be redefined?

EVALUATION OF MOTOR LEARNING METHODS IN YOUTH BASKETBALL PROGRAM

KNJAZ, D., MATKOVIĆ, B., MATKOVIĆ, BR., SWALGIN, K.
FACULTY OF KINESIOLOGY UNIVERSITY OF ZAGREB

Introduction: The aim of this study was to identify the efficacy of three motor learning/teaching methods existing in today's sport, namely, the analytical, synthetic and situational Methods: Method: The sample of subjects was comprised of 90 boys, 9 – 10 years of age, who were beginners in basketball. A six-month program was conducted that, as regards the groups analysed, varied only according to the teaching methods selected. The assessment of effects of certain methods was carried out through the analysis of the development of motor abilities, specific motor skills, that is, the acquisition of basic elements of basketball technique in the play. The effects of the program were analysed by the one-way and multiway analysis of variance. The variables were also analysed by means of the matrix of correlations and by means of comparison of differences between arithmetic means.
The kinesiological influence that the subjects were subjected to, and that included three basketball training sessions per week and the physical education classes, led to significant changes, regardless of the learning/teaching method, in most tests for the assessment of motor abilities (except for the tests for the assessment of muscular endurance and flexibility) and in all tests for the assessment of specific motor skills.
Discussion: The biggest effects achieved in most elements were initiated by the synthetic learning/teaching method; the analytical method proved to be the most successful in the most demanding elements, whereas the positive effects of the situational teaching method were the least expressed.
According to the results obtained and the analysis conducted it may be concluded that the best motor learning/teaching method in basketball training for the population of children of a younger age-group (9 – 10 years of age), beginners in basketball, is the synthetic method. The analytical method should be applied in the teaching/learning process of more structurally complex elements.

HUMAN ACTION, TACIT KNOWLEDGE AND EMBODIED SKILLS

BRUEMMER, K.
UNIVERSITY OF OLDENBURG

Skillful performance in sports requires the ability to master uncertain situations by means of body techniques often under time constraints. It appears obvious that this kind of competence does not only owe to time-consuming planning processes and knowledge-based rationalizations governed by the conscious mind, but also involves the 'intelligence' of an experienced body. Yet, many hegemonic approaches to human action or movement provided in the field of sport sciences focus almost exclusively on those underlying mental processes. Especially in the last couple of years, however, these theories have come under criticism for their intellectualistic stance and reductionist understanding of human action and being. Against the background of this critique, several frameworks have been formulated, claiming that the faculty to react to uncertain situations in a quick and flexible manner constitutively depends on incorporated knowledge and subjective sensations, which are largely tacit and hence difficult to objectify.
In the course of a paradigm shift labeled 'practice turn' [1], in the field of social sciences as well, concepts of tacit knowledge and embodied skills have started to enjoy an increasing popularity with regard to the explanation of dexterous practice. Sociological practice theories maintain that versed action is not only to be attributed to cognitive processes, but draws on incorporated dispositions, too, which had been acquired in collective practices during socialization. Under certain conditions, these dispositions function as a 'practical sense' [2], an intuitive feeling and tacit knowledge for what is to be done, allowing for an immediate, i.e. pre-reflective understanding and flexible coping with a situation. According to the premises of practice theory, this sort of intelligence is not stored in an individual's mind as a subjective possession, but is rather to be regarded as a relational and situational phenomenon emerging in between different (human and non-human) 'actants' [3].
So far, attempts to establish interdisciplinary linkages between the different approaches from sport and social sciences have been rare. Thus, I intend to correlate them in order not only to identify parallels but also to uncover blind spots and shortcomings in the particular concepts and to correct them mutually. It is my prior concern to integrate insights from social practice theory into concepts of motor control and vice versa in order to achieve a more adequate understanding of human activity, which accounts for both sports and everyday situations.

ACTIVE CITIZENSHIP? A SOCIOLOGICAL ANALYSIS OF THE MOTIVATIONS BEHIND VOLUNTEERING IN SPORTS

BLOYCE, D., LOVETT, E., MEAD, R.
UNIVERSITY OF CHESTER

Introduction: The voluntary sector is widely accepted as being of fundamental importance to sport. Game Plan (2002: 9), the British government's strategy for sport, states that 'sport depends heavily on the commitment of thousands of volunteers'. Numerous academics have also highlighted the importance of the voluntary sector in sport (Cuskelly, Hoye and Auld, 2006). Furthermore, volunteering is one of several ways in which the British government is promoting 'active citizenship'. Very little has been written about sports volunteers from the point of view of the volunteers themselves. In this respect, we wanted to discover what motivates people to volunteer, what social factors impact upon the decision to become a volunteer and the pressures faced in volunteering. In addition, given how important volunteers are

deemed to be to professionals working in sport, we also wanted to analyse the relationships between sports development officers (SDOs) and the volunteers that they recruit. We do so from a figurational perspective.

Methods: The study was based upon 14 semi-structured interviews, made up of 11 sports volunteers and three SDOs who made direct use of the sports volunteers.

Results/Discussion: There are numerous motives for people volunteering in sport. This has policy implications for those seeking to recruit volunteers. It also meant that the SDOs that we interviewed did find it increasingly problematic knowing how to recruit and keep volunteers. The growing pressure on SDOs to put in place volunteer programmes, and the increasing requirement that volunteers in sport are subject to official legislation related to their role, has meant that there is a sense in which it is becoming more 'professionalized'. Furthermore, many considered that with competition for sports related jobs there was a necessary requirement to set themselves apart by volunteering. In this respect, some considered that they were, in fact, constrained to be involved. Some volunteers, however, did not identify themselves, necessarily, as a 'volunteer'. They saw it as part of their involvement in playing sport. Whilst this group of volunteers were highly motivated to remain involved, they are also perhaps more likely to stop volunteering the more that they consider official policy encroaching on what they are doing. Finally, the volunteers that we interviewed did not really consider that by volunteering they were deliberately taking an active role in their community. They were volunteering for intrinsic reasons. In this sense it was more about their own habitus than a desire to 'give something back' as an 'active citizen'.

SPORTSPONSORING UND BRAND COMMUNITIES

METHLAGL, M.

UNIVERSITY OF VIENNA

Recent marketing research gains increasing interest in brand communities.

Muniz and O´Guinn (2001, p. 412) define a brand community (bc) as „a specialized, non-geographically bound community, based on a structured set of social relationships among admirers of a brand". The customer-customer-brand triad model of Muniz et al. (2001) was expanded to a consumer centric model by McAlexander, Schouten and Koenig (2002).

Hellmann and Kenning (2007) describe the inner structure of bc using a concentric circle model. These circles constitute the different layers of a community. From an economic point of view these circles represent different target groups for marketing strategies, which should be adopted for each target group inside one community. The focus of recent research are people in the centre of the community (strong engagement, identification, etc.), but periphery has potential for marketing activities too.

Bc are similar to fan clubs in sports (Algesheimer, 2004). Bauer, Exler and Stockburger-Sauer (2007) transfer the construct bc to fan communities in soccer. Their results imply a positive image of the soccer club in the community, which leads to a strong commitment and attachment to the soccer club.

The research project addresses the question if sponsors benefit from bc. Compared to unorganized fans a greater identification with and stronger commitment to the sponsor is suggested for bc. The purpose of this research is to discover the influence of the structure and characteristics of bc in sports on commitment, identification and social representations of the sponsor. To describe the structure the models of Hellmann and Kenning (2007) and McAlexander et al. (2002) is used as a framework. The transformation of the construct bc into a sport context is going to be discussed and specifics of fan communities will be reflected. Relevant variables are going to be considered (interest in sports, global vs. regional communities, etc.). Different fan communities and unorganised fans are going to be surveyed to inspect the relationships in different bc and in the group of unorganised fans, using structural equation modeling.

INVESTIGATION OF CONSUMER-BASED BRAND ASSOCIATIONS OF TURKISH SOCCER TEAMS

ALAY, S., MUMCU, C., KOÇAK, M., KORKUSUZ, F.

1. GAZI UNIVERSITY, ANKARA, TURKEY, 2. UNIVERSITY OF NEW MEXICO, ALBUQUERQUE, NM., 3. MIDDLE EAST TECHNICAL UNIVERSITY, ANKARA, TURKEY.

Introduction: Today, sport managers view their teams, leagues and properties as brands to be managed (Gladden and Milne, 1999). Managing sport teams and their brands are getting more important. To manage sport team brands, it is important to understand consumers because consumers control the creation of brand equity; so it is important to study brand equity from the consumers' perspective (Aaker, 1991; Keller, 1993). Therefore, the purpose of this study was to examine consumers' perception on brand associations and affects of some factors on brand equity of Turkish soccer teams.

Method: In order to measure the consumer-based brand associations of Turkish soccer teams, the Turkish version of Team Association Scale was distributed to 156 undergraduate university students at Middle East Technical University and Gazi University. Independent sample t-test was used to compare gender differences on brand association perceptions, and ANOVA was used to compare the different perceptions of grade levels, user types and soccer teams. Lastly, correlation coefficient was used to look at the relationships among brand associations and independent variables of the study.

Results: Male participants perceived their team more like a brand comparing to females and product, commitment, coach, nostalgia and affect were the factors perceived by males related to brand of their team. Moreover, differences were found among different soccer teams. While Besiktas fans valued star players, Fenerbahce fans viewed management related with brand of their team, and Galatasaray fans related coach and nostalgia and tradition factors to their team's brand image. Lastly, user type groups found to perceive brand associated factors differently. Heavy users perceived their team as a brand more than medium and light users did, and there were differences on the entire brand associations except peer group acceptance.

Discussion: In Turkey, soccer teams and their management have to realize the relevance of their brand in economic success. The key for professional teams is to differentiate their brand by developing and/or strengthening positive associations with team brands in the minds of their consumers (Gladden, Irwin and Sutton, 2001). As a result, management of Turkish soccer teams should market their team using brand associations in consumers' mind such as tradition, product, affect, coach and nostalgia.

"THE BEST SOLDIERS"; A QUALITATIVE STUDY OF "THE BEST SOLDIERS" IN THE NORWEGIAN HOME GUARDS RAPID REACTION FORCES IN THE LIGHT OF PIERRE BOURDIEU'S THEORETICAL PERSPECTIVES.

RONES, N.
NORWEGIAN SCHOOL OF SPORT SCIENCE

In a political situation where it is stressed that defense planning cannot be carried out based on one specific idea as to what kind of threats might face the armed forces in the future, and it is emphasized that the armed forces must adapt to a complex, unpredictable and rapid threat image, it is still desired to select, recruit and educate "the best soldier". It is therefore relevant to question the types of criteria used as a basis for evaluating the soldier's performance, and how" the best soldier" is to be understood when the task to be performed is unknown.
This problem area will be investigated by exploring two questions and the relation between them:
1. Which criteria will form the basis for judging who "the best soldiers" are today?
2. Do the soldiers considered to be "the best" have any similarities in their background experience that may help to explain why they are "best"?
The study is based on a hermeneutic-phenomenological interpretation of qualitative material structured and interpreted with the inspiration of Pierre Bourdieu's habitus-, capital- and field theory.
I will conclude that "the best soldier" must be understood as a construction, constantly restructured in an interaction between historical and cultural structures and the agents' interests and practices. This study can contribute to an extended and critical understanding of the constructions that are made, and show that Bourdieu's perspectives represent a suitable tool for analyzing soldiers in a military field.

DEVELOPMENT OF MEDIA IMPERIALISM IN SPORTS AND EFFECT OF COLONIALIZATION ON OLYMPIC WRESTLING

TIBOR, B.
SEMMELWEIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION

Barna T.,
Semmelweis University Faculty of Physical EducationH and Sport Sciences (TF) Budapest,
Hungary

Introduction: Opposing the practice of the previous centuries, the present day financial and political groups of interests reach their aims not by means of military technique, but via media.
The economic, political and cultural capital piled up by the media empires is the result of a kind of modern colonialization. As a consequence of this kind of colonialization, certain nations and social groups lose their previous identity and become defenceless. Sport cannot be an exception from this either, and it is forced to continuously transform/change in favour of increasing Olympic profit.
The negative trends having formed during the past decade in the content values of wrestling is continuing.
Methods: The followings were applied during 1665 bouts (Olympics, World Championships: WCh'85, Atlanta '96, Athen '04, WCh. '05, WCh ' 07, Beijing '08)
Direct recorded information from the minutes of the bouts
• number of bouts
• duration of bouts
• number of falls
• number of technical points
Indirect observation Methods: • simple attack
• complex attack
• attempted attack and completed attacks are registered on a special survey sheet
Results: 1. As a result of the changing rules of the past years, wrestlers have minimised their actions initiated from standing, have decreased the number of their complex, but spectacular actions, have set themselves for holds worth one or two points. The number of falls and technical falls dramatically decreased in the past years, so - although suitable to TV broadcasting - wrestling has gradually lost its spectacle and spirit.
2. The number of technical points for a time unit decreased, which unambiguously means the devaluation of the contextual value of wrestling, although the length of the bouts shows a tendency to before changes 1985.
Discussion:
• Spectacular throws executed from standing and falls should be valued in a way, that it should mean end of the bout.
• The first action should have a double value and of decisive importance in case of a tie.

EFFECT OF AEROBIC DANCE ON BLOOD PRESSURE IN PREVIOUSLY INACTIVE PREGNANT WOMEN - A RANDOMIZED CONTROLLED TRIAL

EDVARDSEN, E., HAAKSTAD, L.A., HALVORSEN, S., BØ, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: In pregnant women, regular exercise has showed beneficial effects on numerous of health outcomes such as gestational diabetes and pregnant induced hypertension (1). Limited data are available on how regular training affects blood pressure (BP) in pregnant women in rest and during exercise. The aim of the present study was to evaluate the effect of a supervised exercise program on blood pressure at rest (BPrest) and during exercise (BPexercise) in previously inactive non-hypertensive pregnant women.

Methods: 105 healthy sedentary primiparous pregnant women, mean gestational week 17 (SD ± 4,19), mean age 31 yrs (SD ± 4,05), mean BMI 25 (SD ± 4,18), were included in the study. After measurement of BPrest, the subject walked on a treadmill for measuring of BPexercise, heart rate and blood lactate concentration at different sub maximal workloads for establishment of anaerobic threshold (AT). They were then randomized to either an intervention or a control group. The intervention consisted of two to three aerobic dance sessions per week and minimum 30 minutes of daily self-exposed activity the rest of the days. All participants performed a post exercise test at mean gestation week 37 (SD ± 1,03). Mean differences in BT between exercise and control group were analysed by Independent Sample Student's T-test in rest and during AT.

Results: During the training period, drop-out rates were 34,6 % in the exercise group and 47,2 % in the control group. In addition, those subjects who participated in < 80 % of the aerobic dance sessions, or who did not reach AT during the pre-post exercise testing were excluded.

BPrest before intervention was in the exercise (n= 52) and the control group (n=47) 115/66 mmHg (SD ± 11,73/7,30) and 115/67 mmHg (SD ± 10,07/9,06) [mean sys/dia (SD)], respectively (sys: p=0,997, dia: p=0,349). BPrest after the intervention did not change significantly between the exercise (n= 19) and the control group (n=26);3,7/7,6 mmHg (SD ± 9,55/7,52) and 1,3/8,3 mmHg (SD ± 11,54/7,22), respectively. BPexercise at AT before intervention was in the exercise (n=13) and the control group (n=16) 149/61 mmHg (SD ± 14,54/7,26) and 157/62 mmHg (SD ± 9,95/8,53), respectively, and did not change significantly after the intervention (sys: p=0,31, dia: p=0,68).

Discussion: Regular exercise training in previously inactive non-hypertensive pregnant women seems to have no effect on blood pressure at rest and during exercise. Further, rise in blood pressure from rest to AT seems normal in both intervention- and control group in second as well as in third trimester.

IS PELVIC FLOOR MUSLCE STRENGTH TRAINING EFFECTIVE WHEN TAUGHT IN A GENERAL FITNESS CLASS FOR PREGNANT WOMEN? A SINGLE BLIND RANDOMIZED CONTROLLED TRIAL

BØ, K., HAAKSTAD, L.A.H.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: A Cochrane review has shown that pelvic floor muscle training (PFMT) is effective in prevention and treatment of urinary and fecal incontinence in the peripartum period (1). The training programs used in the different randomized controlled trials followed vaginal palpation of ability to perform a correct contraction and were taught individually by trained physical therapists. The aim of the present study was to evaluate the effectiveness of PFMT given in a general fitness class for pregnant women instructed by lay instructors and with no vaginal palpation.

Methods: One hundred and five primiparous women, mean age 30.7 years (SD 4.1) were randomized to either participation in two weekly one hour fitness classes including 35 minutes of low impact aerobic dance, 20 minutes of strength training with emphasize of the abdominals- back and pelvic floor muscles (3 sets of 8-12 close contractions) and 5 minutes of stretching/ relaxation. Outcome measure was number of women reporting urinary, flatus or anal incontinence based on questions from the Severity index and the International Consultation of Incontinence Questionnaire Urinary Incontinence Short Form (ICIQ UI-SF). Comparison of prevalence was done before the intervention (mean gestational week 17.7), after the intervention (mean gestational week 6.6) and postpartum (mean week 7.7). Chi-Square and Fischer Exact tests were used for analyses and p-value < 0.05 was considered statistically significant.

Results: There was no difference in number of women with any type of incontinence before the intervention. Drop-out rates were 21.1 % and 24.5% in the training and control groups, respectively. 27.5% followed all training sessions, with a mean adherence of 17.2 (SD 12.5, range 1-55) out of 24 possible training cessions. Twenty-one women (40.4%) attended ≥ 80% of the training sessions. Number of women reporting urinary, flatus or anal incontinence immediately after the intervention were 17/42, 11/42, 1/42 and 16/42, 9/42, 1/42 in the training and control groups, respectively. Postpartum the corresponding numbers were: 12/43, 10/43, 1/43 and 13/47, 8/47, 3/47, respectively. No significant differences were found between the training and control groups at any evaluation point.

Discussion: There was no effect of a general fitness program including PFMT on reported urinary, flatus or fecal incontinence during pregnancy or after childbirth. The negative findings may be explained by an exceptional low adherence rate, instruction by lay instructors and no assessment of ability to conduct a correct PFM contraction. Future studies are recommended with larger sample size and use of more adherence strategies.

EXERCISE IN THE THIRD TRIMESTER OF PREGNANCY, DOPPLER EXAMINATIONS AND FETAL HEART RATE

BARAKAT CARBALLO, R., CORDERO RODRIGUEZ, Y., RODRIGUEZ ROMO, G., STIRLING, J., ZAKYNTHINAKY, M.

TECHNICAL UNIVERSITY MADRID

Introduction: From a biological viewpoint, pregnancy is a unique process in which the function of all the body's control systems is modified to maintain both maternal and fetal homeostasis. With physical exercise becoming an integral part of life for many women, the question whether exercise during pregnancy may have an adverse impact on the well being of the new born has reached increasing importance.

For healthy pregnant we examined the effect of protocol of moderate exercise (static bicycle) performed throughout the third trimester of pregnancy on circulation (umbilical and cerebral middle arteries) and behavior of fetal heart rate (FHR).

Methods: 20 pregnant healthy women in the third trimester were studied, age= 29.6 ± 4.3 and gestational age 239 ± 14.3 days. Relative to parity 10 of them were nulliparae and 10 multiparae. Exercise protocol consisted of 20 minutes of activity on a static bicycle (50-55% max cap). Pulsatility Index (PI) before and after exercise was obtained from doppler examinations in the umbilical and cerebral middle arteries. Other maternal data were recorded including smoking, occupational activity and physical activity habits.

Results: Our results shows no difference for measurements of IP, before and after exercise, for umbilical artery (p=0.06) and fetal cerebral middle artery (p= 0.10). We found an elevation of FHR between 11-36 beats/min (mean=24±7.6) and significant differences for changes of FHR between parity groups (p=0.04).

Discussion: Certain scientific evidence has demonstrated that physical exercise during pregnancy does not have adverse effects (Barakat et al, 2008; 2009). In that sense, our results shows no differences in IP of umbilical and fetal cerebral middle arteries in agreement with Ertan (2004). Changes in FHR caused by the exercise are a normal fetal reflex (Wolfe et al, 1994).

The results presented support the evidence that moderate exercise during the third trimester of pregnancy does not have a negative influence on neither uterine and fetal circulation nor FHR.

SELF REPORT VS. MOTION MONITOR IN MEASUREMENT OF PHYSICAL ACTIVITY DURING PREGNANCY

HAAKSTAD, L.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Most pregnancy-studies have relied on retrospective, cross sectional surveys to measure physical activity level. Questionnaires are cost-effective, yet validity of the data may be questionable. Objective: The aim of the present study was to validate the Physical Activity and Pregnancy Questionnaire (PAPQ) with a portable activity monitor (ActiReg®, PreMed AS, Oslo, Norway). Design: Prospective comparison study. Setting: Norwegian School of Sport Sciences, Oslo, Norway. Population: Seventy-seven pregnant women wore the ActiReg sensors during waking hours for seven consecutive days and answered the PAPQ. Main outcome measures: Agreement between the two methods was analysed by Bland & Altman plot and Spearman correlation coefficient. Results: The results indicated only small differences between the PAPQ and the ActiReg in cross-tabulation of total physical activity level and proportion of participants meeting the current exercise guidelines. The correlation between the methods was good (r=0.59) for time spent in activities with high intensity (METS>6), moderate for time spent standing/moving (r= 0.36) and fair for sitting/lying (r=0.29). The Bland-Altman plot of the activity patterns, showed a mean difference near zero with no apparent trends and with wide scatter of individual observations. Conclusions: The PAPQ may be considered an acceptable method for assessing habitual physical activity and exercise among pregnant women at group level. However, as questionnaires and portable activity monitors have their strengths in measurement of different aspects of physical activity, there may be several advantages in combining these two types of instruments for registrations of physical activity level during pregnancy.

EXERCISE PRACTICE DURING PREGNANCY

SANTOS-ROCHA, R., CARNIDE, F., RAMOS, L., MAIA, F.

SPORT SCIENCES SCHOOL OF RIO MAIOR - POLYTECHNIC INSTITUTE OF SANTARÉM

According to ACSM and ACOG the benefits of physical activity during pregnancy are well documented and there are general guidelines for exercise prescription based on scientific research. Also, the literature supports the recommendation to initiate or continue exercise in most pregnancies1. The exercise prescription during pregnancy includes the forms of adaptation of the type of exercise, of the intensity, duration and frequency during the different phases of pregnancy: the 1st, 2nd and 3rd trimesters of gestation and the post-partum period (15 to 30 days); and the breast-feeding period. In each one of these phases morphological, physiological and psychological alterations occur which will respectively affect the adaptations of the exercise programs based on effectiveness and safety. However, there is a lack of information on the specific guidelines and real strategies of adaptation of several recreational activities that might be adapted to healthy pregnant women. We believe that in order to better develop safe and effective exercise programs it is necessary to understand, among other variables: the physical activity patterns of pregnant women; the motivations for exercise during pregnancy; and the characteristics of proper exercise. The general purpose of the present study was to characterize exercise practice during pregnancy by means of a questionnaire. Other purposes were to validate the questionnaire and to analyze the motivation for physical exercise during pregnancy. This retrospective study was conducted with a sample of 500 pregnancies. Prior to this analysis, the questionnaire was applied twice to a sample of 100 pregnancies involving 61 women (aged 20-45 years), in order to test the temporal stability (alpha of Crombach test). The average number of days between applications was 51.6 (20.3). The responses obtained in the two applications have shown a high significant correlation. In what is concerned to the characterization of the practice of physical exercise during pregnancy, physical exercise was encouraged by doctors, especially, walking. Most women choose professional oriented physical activity. During the 1st and 2nd trimesters the most popular activities were: strength training, water exercise, swimming and stretching. During the 3rd trimester was the preparation for childbirth. The main reasons behind the practice of physical activity during pregnancy were: the perceived healthy effects on pregnancy and labour; the promotion of mother and baby health and well-being. 76% reported the practice of physical activity before pregnancy, but 52% abandoned it during the 1st trimester. The perceived risk for baby's health was the main

reason for abandonment. 86% had to change or adapt the occupational activity. 73% had to stop work during the 3rd trimester. Physical exercise and diet played an important role during postpartum recovery for 73% of the subjects. The results of the present work will be useful to develop recommendations for pregnancy specific exercise programs.

THE EFFECT OF AEROBIC DANCE ON CARDIORESPIRATORY FITNESS IN PREVIOUSLY SEDENTARY PREGNANT WOMEN - A RANDOMIZED CONTROLLED TRIAL

HALVORSEN, S., HAAKSTAD L.A., EDVARDSEN, E., BØ, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Healthy pregnant women are recommended to be physically active (1). A Cochrane review from 2006 concluded that regular aerobic exercise during pregnancy appears to improve physical fitness, but that the trials are small and of low methodological quality (2). The aim of the present study was to evaluate the effectiveness of a aerobic dance exercise program on cardiorespiratory fitness in previously sedentary pregnant women.

Methods: 105 sedentary primiparous women were randomized to either intervention or control. The intervention consisted of two one-hour aerobic dance sessions per week. The intervention group was also motivated to include 30 minutes of moderate self-imposed physical activity on the rest of the week-days. The control group was neither encouraged nor discouraged from exercising. All the subjects underwent exercise testing by walking on a treadmill for establishment of the relationship between oxygen uptake (VO2), heart rate and blood lactate ([La-]b) at 4-6 different submaximal workloads (lactate profile). Comparison of cardiorespiratory fitness was done before the intervention (mean gestational week 17.7) and after the intervention (mean gestational week 36.6). Analyses were done according to intention to treat (ITT). Independent sample t-test at differences between the groups at anaerobic threshold ([La-]b ∆1.5) (AT) was used for analyses, and a p-value < 0.05 was considered statistically significant.

Results: There were no differences in cardiorespiratory fitness between the groups before the intervention. Drop-outs rates were 34.6 % and 47.2 % in the training and control groups, respectively. On average, those allocated to exercise participated in 17 (SD 12.5) out of 24 possible exercise sessions. 21 women attended ≥ 80 % of the exercise sessions. VO2 at AT decreased with 5,1 % in both the intervention group (mean 25,3 ± 3,7 to 24,0 ± 3,8) and among the control group (mean 24,9 ± 3,7 to 23,7 ± 3,2). Further, there were no significant differences in lactate profile between the intervention and control groups.

Discussion: This study indicates a small negative effect on cardiorespiratory fitness during pregnancy. Our result does not confirm with previous reported findings (3). However, the difference in results may be explained by a much higher fitness level among the participants in the presents study and the unfortunate high drop-out rate and low adherence to the exercise program. Further studies on cardiorespiratory fitness in sedentary pregnant women are needed.

IS-SS01 Contemporary issues of motivation in sport

MOTIVATIONAL CLIMATE EFFECTS ON MOTIVATION REGULATION, PEER RELATIONSHIPS, EMPOWERMENT, AFFECT, AND BULLYING IN SPORT!

ROBERTS, G., OMMUNDSEN, Y., SORENSEN, M., SISJORD, M., FASTING, K.

NORWEGIAN UNIVERSITY OF SPORT SCIENCE

Current approaches to subjective well-being and ill-being in sport suggest that differences in the motivational sport environment, specifically the motivational climate the coach creates within the sport context, may influence psychological outcomes of participation. In the present study, we examined the association of the motivational climate to a range of potential beneficial and aversive psychosocial outcomes of soccer involvement for youths.

The sample consists of a cross-sectional study of 1294 youths aged between 12-16 years of age (Male n = 787, Female n = 507) experienced youth sport participants. Scales assessing the motivational climate and various indices of psychosocial health were administered. Multivariate canonical analyses revealed that a Mastery involving motivational climate was associated with psychologically healthy sport involvement outcomes (RC1 = .48). These outcome variables comprised of higher perceptions of autonomy, positive affect and perceived ability, more autonomous regulation of motivation in that positive associations with intrinsic and identified regulation of motivation were found, positive association with task involvement, and positive peer relationships. Negative relationships were found for external motivation and amotivation. In contrast, a primarily performance involving motivational climate was associated with negative psychological outcomes from soccer involvement (RC2 = .43

The findings suggest that coaches who emphasise winning as the criterion of success in youth sport put the subjective well-being of the participants in jeopardy. Two patterns of relationships were observed, one associated with a mastery climate and indices of subjective well-being, and one primarily associated with a performance climate and indices of subjective ill-being. A focus on mastery is more likely to create a positive experience for the youths that enhances positive outcomes of the sport experience. A focus on performance is more likely to create a negative experience for the youths and enhances negative outcomes.

MOTIVATION AND BURNOUT IN ELITE ATHLETES

LEMYRE, P.N., GUSTAFSSON, H.

NORWEGIAN SCHOOL OF SPORT SCIENCE

While competing in sports large doses of training and high quality motivation are necessary to perform at the elite level (Gould, Dieffenbach, & Moffet, 2002; Lemyre, Roberts, & Stray-Gundersen, 2007). Unfortunately, some of the personal qualities necessary to achieve the highest levels of performance in sports are also risk factors for experiencing debilitating levels of exhaustion often leading to athlete burnout (Lemyre, Hall, & Roberts, 2008). When athletes suffer from burnout, they typically experience chronic fatigue, poor sleep patterns, and bouts of helplessness. They may also complain about episodes of depression related to their sport participation, and not surprisingly their performance is considerably impaired. Previous research findings have established a relationship between athlete burnout and levels of self-determined motivation (Cresswell & Eklund, 2005; Lemyre, Treasure, & Roberts, 2006; Raedeke, 1997).

According to Self-Determined Theory (Deci & Ryan, 2000), on a continuum of self-determined motivation, intrinsic motivation is the most self-determined form of motivation and amotivation is the least self-determined form of motivation, while different levels of extrinsic motivation are found in between. These two forms of motivation are proposed to lie at the opposing ends of a self-determined continuum. Earlier burnout research has found that amotivation is positively and intrinsic motivation negatively associated with burnout (Cresswell & Eklund, 2005b; Raedeke & Smith, 2001). Furthermore, less self-determined motivation in the beginning of the season was associated with burnout at the end of the season in elite athletes (Lemyre et al., 2007). Lemyre and colleagues (Lemyre, Treasure, & Roberts, 2006) also found that motivation shifts along the self-determination continuum to less self-determined motivation during the season was associated with higher burnout susceptibility in swimmers.

Thus, the aim of the current study was to investigate in parallel shifts in self-determined motivation and changes in burnout scores during the season of competition. Participants were 73 national ski academy students (F=42, M=31) competing in xc-skiing (N=44) and ski orienteering (N=29). Each week, for thirteen weeks, athletes answered to a translated version of the Athlete Burnout Questionnaires (ABQ; Raedeke & Smith, 2001) and the Situational Motivation Scale (SIMS; Guay, Vallerand, & Blanchard, 2000). Findings demonstrated a significant negative relationship between shifts in quality of motivation and changes in burnout scores over a 13 weeks period. Decrease in quality of motivation throughout the season is directly linked to an athlete's susceptibility to experiencing feeling burned out. Furthermore, shifts in amotivation throughout the season were a very potent predictor of change in athlete propensity to burn out. Study findings suggest that monitoring quality of motivation of competitive athletes throughout the season may help steer athletes away from maladaptive sport participation outcomes such as exhaustion and burnout.

PASSION FOR SPORT

DONAHUE, E., VALLERAND, R.J.

UNIVERSITE DU QUEBEC A MONTREAL

The purpose of this presentation is to show the applicability of the passion conceptualization (Vallerand et al., 2003) to the realm of sport and exercise. Passion is defined as a strong inclination toward a self-defining activity that people like, that they find important, and in which they invest a lot of time and energy. Two types of passion are proposed: obsessive and harmonious. Obsessive passion refers to an uncontrollable internal urge to engage in the activity that the person likes that results from a controlled internalization of the activity in one's identity. On the other hand, harmonious passion results from an autonomous internalization that leads individuals to choose to engage in the activity that they like. Harmonious passion promotes healthy adaptation whereas obsessive passion leads to less adaptive outcomes. Results from a series of studies with athletes, in a sport setting will be presented, including some on persistence, injury, performance, and subjective well-being. These studies support the role of passion in sport (elite and recreational) and pave the way to new research.

MULTIDIMENSIONAL PERFECTIONISM AND PATTERNS OF ACHIEVEMENT STRIVING

HALL, H.K., HILL, A.P., APPLETON, P.R.

YORK ST. JOHN UNIVERSITY

While perfectionism is seen by some as a universally debilitating personality characteristic, associated with both psychological impairment and distress, (Flett & Hewitt, 2002), others have argued that some forms of the construct reflect an adaptive form of achievement striving (Haase and Prapevassis, 2004; Stoeber & Otto, 2006). This paper presents the findings from three empirical studies examining the relationship between different forms of perfectionism and various patterns of achievement striving. The first study examined the association between positive and negative perfectionism and patterns of achievement striving that included the endorsement of trichotomous achievement goals (Elliot & Church, 1997). A second study examined the association between perfectionism, conscientious achievement striving and maladjustment in junior elite cricket academy players. The third study examined the association between various forms of perfectionism (Hewitt & Flett, 1991) and approach and avoidance achievement goals (Conroy et al., 2003) in a sample of elite junior swimmers. Together, the findings from these three studies suggest that while all forms of perfectionism may lead to positive outcomes, most forms of perfectionism demonstrate a less than adaptive motivational profile.

RESISTANCE EXERCISE TRAINING-INDUCED MUSCLE HYPERTROPHY WAS ASSOCIATED WITH REDUCTION OF INFLAMMATORY MARKERS IN VERY OLD WOMEN.

OGAWA, K., SANADA, K., MACHIDA, S., OKUTSU, M., SHINKAI, S., SUZUKI, K.

TOKYO METROPOLITAN INSTITUTE OF GERONTOLOGY

Aging is associated with low-grade inflammation, which is implicated in a variety of diseases. We investigated the effects of low-intensity resistance training on changes in physical fitness, muscle hypertrophy, and circulating growth factors and markers of inflammation in very old women. Methods: Twenty-one very old women (mean age and SD, 85.0±4.5 years) participated in 12 weeks of low-intensity resistance exercise training, which were included four types of whole body strength training once a week. Physical performance test, muscle thickness, circulating levels of C-reactive protein (CRP), serum amyloid A (SAA), heat shock protein (HSP)70, tumor necrosis factor (TNF)-α, interleukin (IL)-1, IL-6, monocyte chemotactic protein (MCP-1), insulin, insulin like growth factor (IGF)-I, and vascular endothelial growth factor (VEGF) were measured before and after the exercise training. Results: The 12 weeks of low-intensity resistance training increased abdominal ($P<0.01$) and subscapular ($P<0.05$) muscle thickness, whereas it reduced systolic blood pressure ($P<0.05$), and the circulating levels of CRP, SAA (both $P<0.05$), HSP70, IGF-I, and insulin (all $P<0.01$). The plasma concentration of MCP-1, TNF-α, IL-6, or VEGF did not change significantly following the training. The training-induced reductions in TNF-α and CRP were associated with increased muscle thickness ($r= -0.53$, $P<0.05$, $r= -0.61$, $P<0.01$, respectively). Conclusion: Even low-intensity resistance training is beneficial for very old sedentary people as a valid strategy to improve blood pressure, insulin resistance, and muscle thickness and reduce some markers of low-grade inflammation. Resistance training may assist in maintaining or improving muscle volume with reducing low-grade inflammation.

INFLUENCE OF AGEING ON MUSCLE FUNCTIONS OF HUMAN LEG MULTI-JOINT MOVEMENTS

YAMAUCHI, J.

THE UNIVERSITY OF TOKYO/FRIEDRICH-SCHILLER UNIVERSITY JENA

It is important to understand the ageing related differences in muscle function of lower limb multi-joint movements because they are profoundly related to the movements of daily living. Although the contractile properties of isolated muscle have been extensively studied, the influence of ageing on contractile properties of muscles that control the multi-joint movements has not been extensively studied. We have developed the dynamometer with a high time-resolution servo system to obtain the isotonic, force-velocity relation of knee-hip extension movements (Yamauchi et al. 2007). By using this method, muscle functions are precisely evaluated with relatively small physical stress; i.e., without generation of large force to accelerate the inertial mass (Yamauchi and Ishii 2007) and without a large increase in blood pressure (Yamauchi et al. 2008). Therefore, to understand ageing related differences on the maximum force, unloaded velocity and power of leg multi-joint movements, the dynamometer was used to investigate the isotonic force-velocity and force-power relations of muscles that control leg multi-joint movements. In experiment 1, twelve healthy young (age, 19-31yrs) and twelve healthy elderly (age, 60-82yrs) women performed bilateral and unilateral knee-hip extension movements. In experiment 2, two hundred eighty-five recreationally active men (n=142) and women (n=143) aged between 18 and 82 years volunteered for the cross sectional study. In both experiments, the maximum isometric force (Fmax), unloaded velocity (Vmax) and power (Pmax) were determined from the force-velocity relation. Experiment 1 showed that Fmax and Pmax of bilateral and unilateral knee-hip extension movements were 20-30% lower in elderly than in young women. On the other hand, there was no significant change in Vmax between young and elderly women and between bilateral and unilateral movements. Bilateral deficit was larger as the generation of force was larger in both young and elderly women. Also, bilateral deficit of Fmax and Pmax were not different between young and elderly women. Experiment 2 showed that with increasing age, Fmax/body mass significantly declined in both men ($r=-0.400$, $p<0.001$) and women ($r=-0.587$, $p<0.001$), while Vmax/leg length did not change with age in both men ($r=-0.033$, $p>0.05$) and women ($r=-0.040$, $p>0.05$). Pmax significantly declined with age in both men ($r=-0.370$, $p<0.001$) and women ($r=-0.446$, $p<0.001$). Both results showed the ageing related decline in maximum force and power output, but no differences in the intrinsic shortening velocity of leg multi-joint movements. This finding suggests that decreases in muscle force generating capacity and power may primarily lead to the loss of mobility and a reduced capability of accelerating and decelerating the body mass during the movements. Thus, it is important to prevent a loss of force generating capacity of leg multi-joint movements in elderly individuals.

SARCOPENIA AND AGE-RELATED INSULIN RESISTANCE OF MUSCLE PROTEIN METABOLISM

FUJITA, S., VOLPI, E.

UNIVERSITY OF TOKYO AND UNIVERSITY OF TEXAS MEDICAL BRANCH

Sarcopenia is an age-related progressive loss of muscle mass that leads to muscle weakness, limited mobility, and increased susceptibility to injury. Sarcopenia is a multifactorial disorder, and evidence is accumulating that a reduced response of skeletal muscle to anabolic stimuli is an important contributor.

Whereas the addition of carbohydrate to an amino acid meal enhances the amino acid stimulation of muscle protein synthesis in young subjects, such an combination does not have any additive effect on muscle protein synthesis in older subjects, thereby blunting the anabolic effect of the meal on muscle proteins. Since the ingestion of carbohydrate increases endogenous insulin secretion, we explored the hypothesis that aging is associated with a relative insulin resistance of muscle proteins.

Insulin is a potent anabolic stimulus for skeletal muscle. We have measured muscle protein and amino acid metabolism using stable-isotope methodologies in healthy young subjects at baseline and during local insulin infusion into a leg. We found physiological hyperinsulinemia increased skeletal muscle protein synthesis and anabolism in healthy young subjects (157±54%, $p<0.05$ vs. baseline), as long as blood flow and amino acid delivery to the muscle are stimulated by insulin (2). Thus, it appears that the insulin-induced modulation of muscle perfusion and nutrient availability is necessary for the anabolic response of muscle protein synthesis.

Healthy aging is also associated with a decreased insulin-induced vasodilation due to dysfunction of the endothelial-dependent vasodilation, which is normally initiated by insulin via activation of the endothelial NO synthase. We examined the effect of physiological local hyperinsulinemia (0.15 mU/min/100ml leg) on muscle protein metabolism in young and older glucose-tolerant healthy subjects and found that insulin mediated increase in blood flow, amino acid availability, and skeletal muscle protein synthesis was resistant to the action of insulin in older subjects ($p<0.05$ vs. young), which may be an important contributor to the development of sarcopenia (1).

More recently, we have demonstrated that a single bout of aerobic exercise (45-min treadmill walk at 70% HRmax) performed a day prior to insulin infusion improved the age-related insulin resistance of muscle protein synthesis by reducing endothelial dysfunction, improving muscle perfusion and amino acid delivery to the muscle tissue, and enhancing activation of the translation initiation (mTOR pathway) and muscle protein synthesis among healthy old subjects ($p<0.05$ vs. non-exercise control)(3).

Further clinical studies are necessary to investigate whether aerobic exercise may prevent the loss of muscle mass with aging by improving the muscle anabolic response during feeding.

IS-PH02 High-Intensity training to achieve optimal adaptation?

AEROBIC HIGH-INTENSITY INTERVALS IMPROVE MAXIMAL OXYGEN UPTAKE MORE THAN MODERATE TRAINING

HELGERUD, J.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM

It is important to know how different training intensities influence adaptations in physiological parameters when selecting the best training regimen for a specific sport or for improving fitness in the general community. Cardio-respiratory endurance has long been recognized as one of the fundamental components of physical fitness. Maximal oxygen uptake (VO2max) is probably the single most important factor determining success in aerobic endurance sports. At maximal exercise, the majority of evidence points to a VO2max that is limited by oxygen supply, and cardiac output seems to be the major factor in determining oxygen delivery (Wagner 2000).

Improvement in VO2max is directly related to the intensity, duration and frequency of training. However, there are few studies where training protocols of different intensities have been matched for work and frequency. The aim of my presentation is thus to compare training methods of different intensity matched for energy consumption. Up to the level of maximum aerobic velocity, the intensity of training seems to determinate the training response. Intensity and volume of training are, thus, not interchangeable (Helgerud et al 2007). The changes in VO2max correspond with changes in stroke volume of the heart, indicating a close link between the two.

While significant improvements in endurance performance and corresponding physiological markers are evident following submaximal endurance training in sedentary and recreationally active groups, an additional increase in submaximal training (i.e volume) in highly trained individuals does not appear to further enhance either endurance performance or associated physiological variables (Laursen et al 2005). Pilot studies containing massive high-intensity aerobic interval training in endurance athletes will be presented. Both case studies and group studies with elite endurance athletes will be discussed. It seems that, for athletes who are already trained, improvements in endurance performance can be achieved only through high- intensity interval training. Understanding and communicating these new developments in physiological research is probably the least of the problems in terms of changing existing training practices. The challenge is to ensure that this information is acted upon by coaches and athletes.

IS LONG SLOW DISTANCE <LSD> REQUIRED FOR THE ELITE ENDURANCE ATHLETE?

MARTIN, D., BARRAS, M.

AUSTRALIAN INSTITUTE OF SPORT

Australian Track Cyclist Brad McGee won the individual pursuit (4km) at the World Championships in 2002 after completing more than 30,000 km of cycling that year. After racing in Grand Tours (~1400km per week) Brad and his team mates set a World Record in the 2004

Olympic Team Pursuit event (~4min duration). Similarly, track cyclist Shayne Kelly, completed more than 25,000km per year, with a large proportion of LSD training leading up to his three World Championship wins in the kilometre, an event that last ~1min.

Traditionally exercise physiologists have focused on cardiovascular and skeletal muscle adaptations in response to different types of training intensity. However, the effects of endurance training on brain chemistry and function has also become a topic of interest (Dishman, Berthoud et al. 2006). Because movement patterns and corresponding skeletal muscle and cardiovascular load during LSD is not competition specific, and because improvements in VO2max are greatest following high-intensity interval training, some have questioned the efficacy of LSD training (Helgerud, Hoydal et al. 2007).

Perhaps the primary benefits of LSD are brain derived. Joe Henderson, an early adopter of LSD terminology and training practices, focused on the mental compared to physical aspects of LSD. Henderson wrote that "LSD was less a training system than a recovery system. We raced better by staying healthier and happier, not by training harder" (Henderson 1969). Sport specific, high intensity training can lead to desired improvements in aerobic fitness. However this high intensity training is often associated with elevations in stress hormones, body heat, and high impact forces. Some researchers have identified high volumes of high intensity training as the primary cause of "overtraining" (Lehmann, Foster et al. 1993). Animal studies demonstrate that endurance trained animals are more resistant to unavoidable stressors that lead to "learned helplessness" (Greenwood and Fleshner 2008). Exercise can have centrally mediated anti-depressive effects (Dishman, Berthoud et al. 2006) and the effects of endurance exercise on neural structure and function is in different regions of the brain are beginning to be better described (Cotman, Berchtold et al. 2007).

These observations raise the possibility that LSD training may prepare the brain to be more receptive and tolerant to competition specific, high intensity training which then directly leads to improvements in endurance performance in sports like track cycling, rowing and swimming.

HIGH INTENSITY AEROBIC INTERVAL TRAINING: NECESSARY BUT INSUFFICIENT FOR OPTIMAL ENDURANCE PERFORMANCE?

SEILER, S.

UNIVERSITY OF AGDER

Introduction: The athlete´s laboratory is daily training, month after month. The outcome variable is performance. This Darwinian arena sets the stage for a self-organizing process of training optimization based on thousands of athlete-year iterations of the same "experiment" connecting training input and performance outcome.

How do elite endurance athletes train?

Descriptive studies from divergent sports competed over 4-120 min show remarkable consistency in a key training characteristic; about 75 to over 90% of endurance sessions / km / HR zone minutes are typically performed at intensity under VT1, or ≤2mM blood lactate (LSD). Billat et al. (1) reported that elite marathoners (2:06-2:12), performed 75% of their training kms as LSD, 4% at their lactate threshold (race intensity), and 20% above LT. About 85% of the training distance of elite Kenyan 10k runners is actually LSD (2). Elite rowers, who compete over ~6 minutes at ~100% VO2 max intensity, perform 80% or more of endurance training time at ≤ 2mM blood lactate (5, 10). Data from other sports concur (7,8). All of these groups also perform HIT, and often temporarily increase HIT loading in peaking periods, but clearly emphasize large volumes of LSD throughout the training year.

Training studies on athletes

Esteve-Lanao et al (4) compared performance changes in sub-elite runners after 20 weeks of training with either 80-12-8 % or 67-25-8% distribution of training below VT1, between VT1 and VT2, and over VT2. The athletes performing more LSD training improved 10.4 km cross-country time more (157 ± 21 vs 121± 13 seconds, $p<0.05$) than the "threshold training" group. After a 25 day detraining period at <10% full training, 18 national class rowers trained for 12 weeks, either "100% LSD" training (64-74% VO2 peak, n=9, LOW)) or 70% below LT and 30% between 84 and 100% VO2 peak (MIX, n=9). Performance and VO2peak improvement were significant but similar in LOW and MIX. Power at LT and at 4mM [La-] increased more in LOW (6).

Stress Avoidance or Adaptive Signalling Advantage?

Potential driving mechanisms for the emphasis on LSD in top performers may be based on substituting duration for intensity in order to minimize stress responses and overtraining risk (3, 9). Alternatively, low intensity, longer duration training alone or in combination with energy status may elicit cell-signalling advantages that promote greater muscular adaptation. Perhaps it is both.

AN NMR-BASED METABONOMIC EXPLORATION OF CHANGES INDUCED BY HIGH-INTENSITY EXERCISE IN HUMAN URINE

MOUGIOS, V., PECHLIVANIS, A., KOSTIDIS, S., GIKA, H., MIKROS, E., THEODORIDIS, G., SARASLANIDIS, P., PETRIDOU, A.
UNIVERSITY OF THESSALONIKI

Introduction: Metabonomics represents a holistic, hypothesis-free, approach to the study of metabolic responses to various stimuli through powerful data acquisition and advanced data processing techniques that determine tens or hundreds of analytes simultaneously. Metabonomic data related to exercise are scarce.
Methods: Fourteen young, moderately trained, males were equally and randomly assigned to either of two exercise sessions commonly used in sprint training. Both sessions involved three sets of two 80 m sprints. The two sprints in each set were separated by either 10 s (in one session) or 1 min (in the other) of rest, and sets were separated by 20 min of rest in both sessions. Urine was collected before and 35 min after exercise and was subjected to proton nuclear magnetic resonance (1Η-NMR) spectroscopy. Spectra were acquired on a 600 MHz spectrometer and were analysed using multivariate statistical methods including principal component analysis (PCA), partial least squares discriminant analysis (PLSDA), orthogonal partial least squares (OPLS), and principal component variable grouping (PCVG). In PCA, data are represented in K-dimensional space and projected onto few principal components that describe the maximal variation of the samples. Score plots show the relation between data and explain the maximal variation. Loading plots display the relation between variables (signals) and the variables' importance. PLSDA, a supervised linear regression method in which samples are assigned to different classes, includes an added vector characterizing the classes. OPLS filters out variation, provides S-plots and helps in detecting main contributors with the highest confidence. PCVG groups signals according to variation patterns, thus aiding in assigning signals to compounds. Using Student's t test, one can identify the variables with the highest influence on the models.
Results: In both PCA and PLSDA score plots, clear-cut grouping of the samples was afforded according to time (pre- vs. post-exercise) and rest interval (10 s vs. 1 min). Loading plots and further statistical treatment assigned the differences to lactate, compounds of the Krebs cycle (citrate, succinate), amino acids (alanine, glycine, histidine, phenylalanine, threonine), products of branched-chain amino acid catabolism (oxoisocaproate, isovalerate), short-chain carboxylic acids (butyrate, propionate, formate), 3-hydroxybutyrate (a ketone body), hippurate, and dimethylamine.
Discussion: The present study illustrates the utility of holistic analytical methods (rather than targeted analysis of a small number of analytes) in the study of exercise metabolism. Samples differing in as little as the rest interval between repeated sprints can be classified and predicted. In this way, important biomolecules involved in exercise biochemistry can be identified and further studied. The fact that such methodology can be applied to biological material obtained non-invasively (urine) is an added value.

ANALYSIS OF HUMAN PROTEIN AND ENERGY METABOLISM: APPLICATION OF A NEW METHOD IN SPORTS

HUELSEMANN, F.
GERMAN SPORT UNIVERSITY COLOGNE

For many years the analysis of nitrogen stable isotope ratio analysis at natural abundances of animal tissue and urinary components has been used in ecology. Isotope ratio mass spectrometry (IRMS) was used for the interpretation of nutritional status and metabolic conditions of individuals and populations as well as for the exploration of food webs. For humans it has been shown that anabolic or catabolic conditions can be identified by segmental analysis of hair. Due to isotopic fractionation during nitrogen metabolism within the body dietary and body nitrogen exhibit significantly different natural isotope ratios. Therefore variations in natural stable nitrogen isotope ratios of tissue or urea allow for the estimation of the proportion of metabolized body nitrogen in comparison to dietary nitrogen. IRMS of natural variations in nitrogen isotopes expand the scope of analytical methods for studies of energy and protein metabolism in addition to conventional tracer experiments. In contrast to tracer experiments studies at natural isotope ratios do no require administration of labeled substances. Whereas nitrogen isotope ratio analysis of urea provides information about actual metabolic conditions the analysis of human hair enables a retrospective examination of an individual's energy and protein metabolism.
By IRMS of segmented hair we were able to identify catabolic and anabolic conditions of an athlete's metabolism that resulted from varying nutritional statuses and levels of physical activity. Nitrogen isotope ratios of hair segments were significantly associated with energy balance and protein intake. Identical patterns of correlation between natural stable nitrogen isotope ratios and energy balance and protein intake were detected by IRMS of urinary urea for athletes prior, during and after a 24-hour bicycle race. In contrast to the period before the race, during the race an increased excretion of body nitrogen could be detected by IRMS for the athletes with the most negative energy balance and the lowest protein intake. After the race an inverse situation was reached as athletes excreted high amounts of isotopically light nitrogen due to high amounts of protein intake.
Variations in natural nitrogen isotope ratios of urea yield additional information about the human energy and protein metabolism when compared to excreted urea concentrations. The analysis of natural stable nitrogen isotope ratios of human tissue and urinary components is capable to provide additional insights into human energy and protein metabolism besides existing analytical techniques.

CYTOKINE PRODUCTION BY MONOCYTES, BUT NOT NEUTROPHILS, IS HAMPERED BY LONG TERM INTENSIVE TRAINING IN ELITE SWIMMERS

TEIXEIRA, A.M., RAMA, L., MORGADO, J.M., AZEVEDO, S., MATOS, A., HENRIQUES, A., ROSADO, F., ALVES, F.
1. UNIVERSITY OF COIMBRA, 2. CENTRO DE HISTOCOMPATIBILIDADE DO CENTRO;

Introdution

The relationship between exercise and infection incidence may depend on the intensity and duration of the activity. The aim of the present study was to investigate the influence of long term intensive training over the functional features of innate immune cells from high competitive level swimmers, particularly concerning the production of inflammatory mediators.

Methods: We adopted a single group repeated measures design to study 18 swimmers. Blood samples were collected after 36hours of rest from exercise at four times during the training season: 1) in the beginning of the winter season, after an off training period of 5/6 weeks (t0) 2) after 7 weeks of training (t1) 3) at the 25th week (t2) and 4) at 29th week of training. We looked at the production of IL-1beta, IL-6, IL-12, TNF-alpha and MIP-1beta by neutrophils and monocytes with or without stimulation. The blood samples were incubated in the presence or the absence of LPS and IFN-γ and the frequency of cytokine producing cells and the amount of each cytokine produced by cell were evaluated by flow cytometry. Monocytes were identified by the expression of CD33, CD14, HLA-DR and by their FSC and SSC characteristics. Neutrophils were identified by their particular FSC and SSC characteristics and the absence of HLA-DR.

Results: The frequency and absolute numbers of neutrophils and monocytes did not significantly change during the season with the exception of a decrease in the absolute numbers of monocytes between t0 and t1.

Without stimulation, no significant frequencies of cytokine producing cells were observed during the season with the exception of MIP-1beta. The 6h stimulation with LPS and IFN-γ, did not induce cytokine expression by neutrophils.

The number of cytokine producing monocytes significantly decreased during the season. Additionally the amount of IL-1beta, TNF-αlpha and MIP-1beta produced by these cells in response to stimulation also decreased during the training season. The differences were most noticeable between the first (baseline values) and second blood collections, corresponding to the initial increment of training volume. The exceptions were IL-6 and IL-12 that decreased from t0 to t1 but with no statistical significance.

Conclusions

Our results support the idea that long term intensive training may affect the ability of monocytes to produce important cytokines involved in immune function responses reducing the cells capacity to respond to acute challenges, like an infectious agent, possibly contributing to an elevated risk of upper respiratory tract infections (URTI) episodes in athletes.

ACTN3 R577X AND ACE I/D GENE POLYMORPHISMS IN BULGARIAN ATHLETES

ANDONOV, S., SARAEVA, R., ANDONOVA, S., KANEVA, R., BACHEV, V., BONOV, P., KREMENSKI, I., ATANASOV, P.

NATIONAL SPORTS ACADEMY

Strength and speed human biomotor capacities are strongly genetically inherited, thus further influence with external stimuli (physical loading) when lack predisposition is almost impossible. The aim of this study was to analyse ACTN3 R577X and ACE I/D gene polymorphisms among 70 professional athletes, divided into three groups according to a power-time model, and 44 controls from Bulgarian population. Correlations have been made between genotypes and physiological and biochemical parameters at anaerobic conditions, using Wingate test. Genotyping was performed by RFLP analysis. We found that ACTN3 RR and RX genotypes significantly correlate with Peak Power Output (p=0,0004 and 0,004), Relative Power Output (p=0,0002 and 0,002) and Fatigue Index (p=0,04). Lactate Dehydrogenase enzyme activity was also statistically different in genotype before and after the Wingate test. In contrast, there were no significant differences when referred to XX genotype athletes and controls of those parameters. R-allele frequency was higher in Endurance group (0,70) than Anaerobic Capacity Group (0,50) (p=0,004), contrary to the prevailing data showing association of endurance with X-allele. ACE ID genotype athletes have significantly different PPO and RPO from ID controls, an observation which was not present in DD and II genotypes. We therefore conclude that XX genotype is unfavourable for speed/power performance. Higher R-allele frequency may lead to positive influence over the power component in endurance sports. Furthermore, the presence of D-allele in ACE heterozygous persons also indicates favourable conditions for speed and strength capacities development.

ADIPOSE TISSUE TRIACYLGLYCEROL LIPASE ACTIVITY IN LEAN AND OBESE MEN DURING AEROBIC EXERCISE

PETRIDOU, A., CHATZINIKOLAOU, A., MICHAILIDIS, I., FATOUROS, I., JAMURTAS, A.Z., MOUGIOS, V.

ARISTOTLE UNIVERSITY OF THESSALONIKI

Introduction: Triacylglycerol lipase catalyzes the committed step in the hydrolysis of triacylglycerols stored in adipose tissue. In our laboratory, we have studied triacylglycerol lipase activity (TGLA) in the adipose tissue of lean men during aerobic exercise by using a novel assay of the actual enzyme activity against endogenous triacylglycerols (Petridou and Mougios 2002). Through the same assay, we have recently found a delayed lipolytic response to resistance exercise of obese compared to lean men, which may be due to the unusual increase in the antilipolytic hormone, insulin, in the obese during exercise (Chatzinikolaou et al. 2008). The aim of the present study was to monitor and compare acute changes in adipose tissue TGLA during aerobic exercise between lean and obese men.

Methods

Sixteen young men, 7 lean (BMI < 25 kg/m2, body fat < 15%) and 9 obese (BMI > 30 kg/m2, body fat > 20%), participated in the study. After an overnight fast, the participants cycled for 30 min at a heart rate of 130-140 beats min-1. Needle biopsy from the gluteal adipose tissue was performed at baseline and at 5, 10, 20, as well as 30 min of exercise. VO2 and respiratory exchange ratio (RER) were monitored continuously throughout exercise via a portable gas exchange analyzer. TGLA was determined by measuring the decrease of endogenous triacylglycerol concentration during incubation of the homogenized tissue (Petridou and Mougios 2002). Differences were examined through two-way (group by time) ANOVA with repeated measures on time. The level of statistical significance was set at 0.05.

Results: There was a significant interaction of group and time and a significant main effect of time. Adipose tissue TGLA increased significantly at 10 min of cycling in the lean and returned to baseline at 20 and 30 min, whereas, in the obese, TGLA was significantly higher than baseline only at 20 and 30 min of exercise. As a result, TGLA was higher in the obese at 20 and 30 min of exercise.

Discussion: Our data suggest sustained adipose tissue lipolysis during aerobic exercise in obese men, as opposed to a decline in lipolytic rate after an initial rise in lean men. Hormonal analyses are currently under way to elucidate the mechanism of the different lipolytic response to exercise between lean and obese men.

PASSIVE HEATING AT HIGH CORE TEMPERATURE DOES NOT INCREASE PLASMA HSP72

RUELL, P., THOMPSON, M., CHAPMAN, P., HOFFMAN, K.

THE UNIVERSITY OF SYDNEY

Heat shock protein 72 (HSP72) of molecular weight 72 kDa is found both in the intracellular environment where it is strongly induced by heat and other stressors, and in the plasma where it is upregulated by exercise (Ruell et al., 2006). In the intracellular milieu HSP72 has a protective role, making the organism more resistant to a second stressful event. The role of HSP72 in the plasma, however, is less clear. It appears to act as a danger signal to the organism and high extracellular levels may lead to the release of cytokines. It has been shown that passive heating to a temperature of 38.5°C in humans does not elicit an increase in plasma HSP72 (Whitham et al., 2007). The aim of the present experiment was to determine whether raising rectal temperature to 39.5°C by passive heating would increase plasma HSP72.

Methods: Eleven male subjects were recruited to participate in the experiment. Subjects were seated in a bath and warmed by immersion to the waist in water heated to 42 – 43°C. Rectal temperature was monitored using a dataTaker DT500 system. Blood samples were taken before and immediately after the bath. Blood was centrifuged and the plasma frozen at -85°C until analysis for plasma HSP72 using a commercial kit (Stressgen, Canada). Samples were diluted 1/5 before analysis. Blood was also taken to determine monocyte HSP72 in 6 subjects. 14 ml EDTA blood was mixed with 6% dextran and allowed to stand at room temperature for 45 min. The leukocyte rich layer was then layered over Nycoprep 1.098 (Axis-Shield, Norway) and centrifuged at 600g for 15 minutes, and the monocyte layer removed and washed, then frozen. The pellet was later extracted and analysed for HSP72 by Western blotting using the Stressgen antibody SPA-810.

Results and Discussion: The mean age and weight of the subjects was 27.6 ± 1.2 years and 71.4 ± 2.3 kg. Subjects sat in the bath for 74.4 ± 3.6min, and the maximum Trec reached was 39.7± 0.1° C. Mean plasma HSP72 was 1.0 ng/ml before the bath and 1.3 ng/ml immediately post (not significant). Thus, increasing core temperature to a higher level does not significantly elevate plasma HSP72. In contrast, in a subset of subjects, monocyte HSP72 was significantly higher 19 hours after the passive heating compared with resting levels. It appears that heat alone is not the trigger for the increase in plasma HSP72 after exercise.

INTRALUMINAL ADENOSINE: MECHANISMS OF ACTION AND POTENTIAL ROLE DURING EXERCISE HYPERAEMIA IN HUMANS

NYBERG, M., MORTENSEN, S.P., THANING, P., SALTIN, B., HELLSTENAND, Y.

THE COPENHAGEN MUSCLE RESEARCH CENTRE

The present study examined the contribution of adenosine to exercise hyperaemia and the mechanisms by which intraluminal adenosine induces vasodilatation. We measured leg haemodynamics before and during intra-arterial adenosine infusion (0.30±1 µmol min-1 kg leg mass-1; n=13;) In addition, plasma adenosine concentrations were determined in plasma dialysate sampled with a novel type of intravascular microdialysis probes during rest and one-legged knee-extensor exercise (16±3 W and 31±6 W; 20 and 40 % of peak power; mean ± S.E.M.; n=8). Leg blood flow (LBF) was measured with the constant-infusion thermodilution method.

Adenosine was infused alone (CON) or during infusion of the nitric oxide (NO) synthase inhibitor (L-NMMA) and/or the cyclooxygenase inhibitor (indomethacin (INDO)). During adenosine infusion, LBF increased from a basal value of 0.33±0.03 l min-1 to 2.65±0.27 l min-1. When adenosine was co-infused with L-NMMA, INDO, or L-NMMA + INDO the adenosine-induced increase in LBF was reduced ($P<0.05$) by 35±8, 50±3 or 61±8 %, respectively. Exercise increased LBF from 0.21±0.04 to 2.35±0.20 and 4.00±0.53 l min-1. Arterial plasma [adenosine] was 52±11 nM at rest and 38±13 and 67±27 nM during the two exercise intensities, respectively. Similarly, venous plasma [adenosine] was 32±12, 20±7 and 16±4, respectively. Interestingly, when accounting for LBF, the arterial plasma delivery of adenosine

increased (P<0.05) from 11±4 nmol min-1 at rest to 337±167 nmol min-1 during exercise at ~30 W. Similarly, the venous plasma efflux of adenosine increased from 3±1 nmol min-1 at rest to 79±18 nmol min-1 during exercise.

These results show that a large part of the vasodilatory effect of intraluminal adenosine is mediated by formation of NO and prostaglandins. Furthermore, the fact that the reduction in adenosine-induced vasodilatation was greater with prostaglandin inhibition than with NO inhibition, and that the effects of prostaglandin and NO inhibition were not additive, indicates that NO formation in part may be mediated by prostaglandins. Finally, plasma adenosine concentrations during exercise, shows an increase in the arterial plasma adenosine delivery, but to what extent this contributes to skeletal muscle blood flow warrants further investigation.

ERYTHROCYTE CONTROL OF SKELETAL MUSCLE CIRCULATION: INSIGHTS FROM STUDIES IN MITOCHONDRIAL MYOPATHY PATIENTS

JEPPESEN, T.D., VISSING, J., GONZÁLEZ-ALONSO, J.

NEUROMUSCULAR RESEARCH UNIT 3342

Introduction: Oxygen (O2) extraction and utilization is impaired in exercising skeletal muscle of patients with mutations of mitochondrial DNA (mtDNA), a phenomenon hypothesized accompanied by hyperkinetic circulatory response. Implications of exaggerated muscle perfusion in concert with high levels of oxyhemoglobin, suggests that impaired mitochondrial function is associated with dysfunction in erythrocyte-derived vascular signalling or -response. In this study, erythrocyte- and vascular ATP control of skeletal muscle blood flow was investigated in patients with mutations of mtDNA.

Material and methods: Ten patients with mutations of mtDNA and ten matched healthy control subjects were recruited for the study. Leg blood flow (LBF) and femoral arterial and venous blood oxygenation and plasma ATP were examined at rest, during severe systemic hypoxia, hyperoxia, intrafemoral ATP infusion, and during passive and dynamic one-legged knee-extensor exercise.

Results: During hypoxia, hyperoxia, ATP infusion and passive exercise, erythrocyte oxygenation, plasma ATP, LBF and VO2 response were similar in patients with mtDNA mutations and healthy subjects. During dynamic submaximal and maximal knee-extensor exercise, however, LBF and vascular conductance were higher and leg O2 extraction and -VO2 lower in the patients vs. healthy subjects. The increased LBF and arterial and venous O2 content was accompanied by enhanced venous and arterial plasma ATP and norepinephrine concentrations.

Conclusions: The appropriate hemodynamic adjustments during severe hypoxia and ATP infusion in patients with mtDNA mutations, suggest that erythrocyte- and vascular endothelial blood flow regulating mechanisms are intact in these conditions. The increased ATP- and LBF levels in concert with unchanged oxyhemoglobin in the patients with mtDNA mutations, suggest that ATP, at least in part, is responsible for the hyperkinetic muscle perfusion in these conditions. Moreover, the findings demonstrate that, at least in patients with mitochondrial dysfunction, O2 offloading from hemoglobin is not obligatory for plasma ATP release.

EFFECTIVENESS OF INTERMITTENT TRAINING IN HYPOXIA COMBINED WITH LIVE HIGH/TRAIN LOW

ROBERTSON, E.Y., SAUNDERS, P.U., PYNE, D.B., GORE, C.J., ANSON, J.M.

AUSTRALIAN INSTITUTE OF SPORT; UNIVERSITY OF CANBERRA; FLINDERS UNIVERSITY

Introduction: Many elite athletes undertake some form of altitude training in an attempt to gain small improvements in fitness and performance that provide a competitive advantage. Overall, natural or simulated live high/train low (LHTL) can offer ~1-2% improvements in performance [1]. For athletes who cannot undertake several weeks of LHTL, an alternative approach of performing some but not all training sessions in hypoxia (train high, TH) can elicit hypoxia-induced adaptations and allow athletes to maintain high training loads [2]. No previous study has addressed a combined approach of LHTL plus TH (LH/TH) to enhance performance gains in a single altitude camp.

Methods: Seventeen well-trained male (VO2max: 68.6 ± 5.0 ml/kg/min, mean ± SD) and female (VO2max: 55.5 ± 3.1 ml/kg/min) runners trained in normobaric hypoxia for 3 weeks (2200 m, 4 times per week). During this period the LH/TH group (n=8) spent 14 h/d in a hypoxic chamber (3000 m) while the TH group (n=9) lived near sea-level (600 m). All other training was performed near sea-level (600 m). Laboratory (treadmill, VO2max) and field (3-km time trial) performance tests were completed before, and within 2-4 days of altitude training. A third 3-km time trial was completed 2 weeks later. Haemoglobin mass (Hbmass) was measured twice before, weekly and one week after altitude training. Data were log-transformed for the analyses to reduce bias arising from non-uniformity of error. Mean percent effects and their 90% confidence limits (CL) were estimated via the unequal-variances t statistic computed for change scores between pre- and post-tests [3].

Results: The LH/TH group substantially improved VO2max (4.8%; ±2.8%, mean; ±90% CL), Hbmass (3.6%; ±2.4%) and time trial performance (-1.1%; ±1.0%) immediately after altitude training. The TH group improved VO2max (2.2%; ±1.8%), with only trivial changes in Hbmass (-0.7%; ±2.0%) and time trial performance (-0.1%; ±1.0%). The magnitude of improvements in the LH/TH group was substantially greater than TH: improved VO2max (2.6%; ±3.2%), increased Hbmass (4.3%; ±3.2%), and faster time trial performance (-0.9%; ±1.4%). Neither group substantially improved 3-km time trial two weeks after altitude training compared with the pre-test (LH/TH: -0.4%; ±1.3%, TH: -0.6%; ±1.1%).

Conclusion

Three weeks of combined LH/TH can induce substantial increases in VO2max and Hbmass, and trivial to small improvements in time trial performance. Three weeks of TH alone was sufficient to improve VO2max, but Hbmass and time trial performance were essentially unchanged. LH/TH elicits greater enhancements in physiological capacities that underpin competitive performance compared with TH, however, transfer of these physiological adaptations to 3-km time trial performance was more variable.

LACTATE RELEASE IN EXHALED BREATH CONDENSATE AT REST AND DIFFERENT LEVELS OF EXERCISE IN YOUNG AND HEALTHY SUBJECTS

MAREK, E., VOLKE, J., HAWENER, I., MÜCKENHOFF, K., MAREK, W., PLATEN, P.

RUHR-UNIVERSITY BOCHUM

Background: Traditionally, lactate is measured from arterialized earlobe blood samples. Currently developed micro enzyme detectors permit a non-invasive measurement of lactate in exhaled breath condensate (EBC). This method might be interesting for the combined use with spirometric measurements of O2 consumption and CO2 release. In order to get inside into the correlation of lactate concentration or lactate release in EBC and in lactate blood concentrations, we investigated both parameters at rest and at different levels of exercise in a group of young and healthy subjects.

Methods: The study group 16 healthy subjects consists of 7 females and 9 males (23.3 ± 1.5 years, 175 ± 8,4 cm height, 68.9 ± 9.2 kg body weight). During resting conditions as well as at 60%, 75%, and 90% of maximal work capacity (each lasting for 5 minutes) on a cycle ergometer 100 L exhaled air along with capillary blood samples from the earlobe were collected under stationary load conditions. EBC was obtained by cooling the exhaled air volume to -20°C. The condensates were analysed using an ECo-Check amperometer (Viasys Health Care). Lactate measurements were performed using a bi-enzym-sensor after lactate oxidase induced oxidation of lactate to pyruvate and H2O2. The rates of expiratory release of lactate in nmol/min were calculated from the concentrations of lactate in the EBC, the EBC volume and the time of collection. A functional relation of lactate release and lactate concentration of arterial blood was computed.

Results: At rest lactate concentration in arterialized blood was 0.92 ± 0.31 mmol/L. At a resting ventilation of 12.0 ± 3.8 L/min, collection time (Ts) for 100 L exhaled air, was 8.9 ± 2.6 min, and 1.86 ± 0.66 ml EBC were obtained. In EBC lactate concentration was 24.5 ± 9.4 µmol/L, lactate release rate was 4.8 ± 1.8 nmol/min.

At 90% maximal work capacity (external load 200 ± 20 Watt), blood lactate concentration increased to 8.4 ± 1.6 mmol/L and ventilation increased to 83.8 ± 16.0 L/min. EBC collection time decreased to 4.7 ± 2.1 min ($p<0.01$) and 1.30 ± 0.46 ml EBC were obtained. Lactate concentration in EBC increased to 41.7 ± 11.7 µmol/L ($p<0.01$), and lactate release in EBC increased to 12.1 ± 4.7 nmol/min ($p<0,01$). The correlation of lactate release in exhaled air and lactate concentration in arterialized blood can be described by an exponential function (y = 9,93*e^0,144x, r = 0,64, a<0,01).

Conclusions: Release of lactate was found in exhaled breath condensate already under resting conditions. At increasing levels of external load, an increase in the lactate concentration was found in arterialized blood as well as in EBC. This method might be used in future for the analysis of lactate and metabolites during exercise.

CEREBRAL VASCULAR RESPONESE TO CO2 DURING VOLITIONAL EXHAUSTION

HIURA, M., IZUMI, S., FUJIMOTO, T.

HOSEI UNIVERSITY

CEREBRAL VASCULAR RESPONESE TO CO2 DURING VOLITIONAL EXHAUSTION

Hiura, M.1, Izumi, S.1, Fujimoto, T.2

1Faculty of Sports and Health studies, Hosei University, Tokyo, Japan

2Department of neurosurgery, Showa University, Tokyo, Japan

Introduction: Cerebral vascular response to PaCO2 change was established with regional cerebral blood flow (rCBF) measurement in resting condition. During exercise the middle cerebral artery mean blood velocity (MCA Vmean) has been alternatively induced as index of rCBF because its capability for real time monitoring. The aim of this study was to evaluate CO2 reactivity during incremental exercise by spontaneous change in PaCO2 using MCA Vmean and to compare the results with the previous studies.

Methods: Eight healthy young male (mean ± S.D, ; age 21 ±1years) were participated in the present study. During incremental exercise tests using cycle ergometer, respiartory gas exchange was measured by an on-line analyzer (CPET, Cosmed , Italy) and MCAV mean was measured by transcranial Doppler (Companion III, Nicolet Vacular, USA). Exercise intensities at anaerobic threshold (AT), respiratory compensation threshold (RCT) and volitional exhaustion (Max) were determined and PaCO2 was estimated using the equation described by Jones and colleagues (ePaCO2).

Results: At baseline ePaCO2 was 38.4±3.3 mmHg and increased significantly to 43.6±4.9 mmHg at RCT ($P<0.001$). At Max, ePaCO2 decreased to 39.8±4.1 mmHg from RCT ($P<0.01$). MCA Vmean also increased from baseline by 39.4±21.1 % ($P<0.01$) at RCT and decreased at Max from RCT by 14.9±13.0 % ($P<0.05$). Since nearly stable hypercapnic condition was recognized between AT and RCT, cerebral vascular response to CO2 in hypercapnia was calculated using the change in ePaCO2 and MCA Vmean between baseline and the hypercapnic state, whereas the response to CO2 in hypocapnia was calculated between the hypaercapnia and Max. The cerebral vascular responses to CO2 were 5.0±1.8 % and 6.1±1.5 % in hypercapnia and hypocapnia, respectively.

Discussion: Cerebral vascular response to PaCO2 in hypercapnia in the present study was nearly identical to that of resting condition (Peebles et al 2007, Valdueza et al 1999) but the response in hypocapnia was higher than that of previous reports. This enhanced CO2 reactivity corresponded to the previous study (Rasmussen et al 2006). Although the present study has limitation that the steady state of hypo- and hypercapnia was not strictly induced, it speculated that rCBF would decreased during volitional exhaustion more than expected from change in PaCO2 for resting condition.

DO SKELETAL MUSCLE MITOCHONDRIA PLAY A ROLE IN THE REDUCTION OF VO2MAX WITH MODERATE HYPOXIA IN ENDURANCE ATHLETES?

PONSOT, E., DUFOUR, S.P., DOUTRELEAU, S., LONSDORFER-WOLF, E., LAMPERT, E., PIQUARD, F., GENY, B., METTAUER, B., VENTURA-CLAPIER, R., RICHARD, R.

HÔPITAL CIVIL AND UNIVERSITÉ DE STRASBOURG

Introduction: Hypoxic environments have repeatedly been observed to depress VO2max during whole-body exercise in humans (Fulco et al., 1998). The mechanisms behind the wide interindividual variability of the reduction of VO2max with hypoxia are largely unknown, especially in a homogenous group of athletes (Lawler et al., 1988; Robergs et al., 1998). The present study investigates the role of cardiac output (Q), arteriovenous oxygen difference (DavO2) and mitochondrial function in the limitation of VO2max with moderate hypoxia (FIO2=14.5 %) in a homogenous group of endurance athletes.

Methods: 15 endurance trained athletes (normoxic VO2max =58.6±1.7 ml/min/kg) performed maximal cycle incremental tests to assess VO2max, Qmax and DavO2max in normoxia and moderate hypoxia. Muscle biopsies of vastus lateralis were taken one week before the cycling tests to evaluate the maximal muscle oxidative capacity (Vmax) and the sensitivity of mitochondrial respiration to ADP (Km) with and without creatine (Cr) on permeabilized muscle fibers in situ.

Results: Athletes exhibiting the largest reduction of VO2max in moderate hypoxia (SL group: -18±2%) suffered from both significant reductions in Qmax (-4±1%) and DavO2max (-14±2%). Athletes who tolerated well hypoxia, as attested by a significantly smaller drop of VO2max with hypoxia (ML group: -7±1%), also displayed a blunted Qmax (-9±2%) but, conversely, were able to maintain DavO2max (+1±2%;). Even though Vmax was similar in the two experimental groups, the smallest reduction of VO2max with moderate hypoxia was observed in those athletes presenting the lowest apparent Km for ADP in presence of creatine (Km+Cr).

Conclusion

In already trained athletes with high muscular oxidative capacities, the qualitative rather than quantitative aspects of the mitochondrial function may constitute a limiting factor to aerobic ATP turnover when exercising in lower oxygen availability, presumably through the functional coupling between the mi-CK and ATP production. This study suggests a potential role for peripheral factors, including intrinsic mitochondrial properties, in determining the tolerance to hypoxia in maximally exercising endurance-trained athletes.

EFFECTS OF CONTRACTION ON PATELLAR TENDON MOMENT ARM AND FORCES DURING ISOMETRIC AND ISOKINETIC KNEE EXTENSION

BALTZOPOULOS, V., TSAOPOULOS, D., RICHARDS, P.J., MAGANARIS, C.

*MANCHESTER METROPOLITAN UNIVERSITY; *UNIVERSITY HOSPITAL OF NORTH STAFFORDHSIRE NHS TRUST*

Accurate values of moment arms are of vital importance for accurate calculation of internal muscle-tendon and joint forces. During knee joint extension, patellar tendon (PT) moment arm length (dPT) has been quantified from cadaveric data or in vivo imaging at rest. However, moment arms change with muscle contraction (Tsaopoulos et al., 2007) and it is well recognized that moment arms at the time the load is exerted are required for the realistic estimation of muscle and joint forces. The purpose of this study was to calculate the PT force using contraction-specific moment arm measurements during isometric, isokinetic concentric and eccentric knee extensions.

Eleven healthy males (age: 25.3 years, height: 178.4 cm, body mass: 72.3 kg) volunteered for this study after signing informed consent and radiation risk information forms. The maximum radiation exposure time was limited to 15 s for each person giving a maximum effective radiation dose <1.5 microSv. The experimental procedures were approved by the local ethical committee. Right knee extensions were performed on a Cybex Norm that was fitted with an extended input arm, to allow a gap (45 cm) between the chair and the main unit to accommodate the image intensifier of a GE FlexiView 8800 C-arm X-ray video system that was recording at 25 Hz. Before each trial, the most prominent point of the lateral femoral epicondyle was aligned with the dynamometer axis of rotation using a special laser pointing device. The alignment was performed at 90 deg of knee flexion under submaximal muscle contraction conditions. On the X-ray images recorded the dPT was measured as the perpendicular distance from the tibiofemoral contact point to the PT action line. PT force was calculated: 1) by dividing the actual maximum joint moment during isokinetic and isometric knee extensions with the contraction-specific dPT measurements and 2) by dividing the actual maximum joint moment during isokinetic and isometric knee extensions with the resting-state dPT data.

The differences between resting-state and contracting state moment arm length measurements yielded different estimates of PT force. The use of resting-state dPT values resulted in overestimated PT force by ~273 N (5.8%) and ~764 N (26%), during maximum isometric contractions at 90 and 20 deg of knee flexion angle respectively, compared with calculations using dPT values during MVC. The use of

dPT values from passive extension (resting state) lead to overestimated PT force by ~383 N (15%) and ~521 N (15%), during maximum concentric and eccentric knee extensions respectively.

The erroneous PT force values would overestimate stress of the PT and can lead to erroneous conclusions regarding the risk of tendon injury during daily living activities. These findings also indicate that significant errors may have been made by previous studies in estimations of PT force and stress using resting dPT measurements.

CADAVERIC VERSUS ULTRASONOGRAPHIC ASSESSMENT OF THE LONG HEAD OF BICEPS FEMORIS AND SEMINTENDINOUS MUSCLE ARCHITECTURE

KELLIS, E.

ARISTOTLE UNIVERSITY OF THESSALONIKI

The purpose of this study was to document and compare the architectural parameters (fascicle length, angle of pennation, muscle thickness, tendon length) of the long head of biceps femoris (BFlh) and semitendinosus (ST) muscles measured from direct dissection as opposed to those measured using ultrasound (US). The BFlh and ST were examined bilaterally in 6 legs from 3 male cadavers (mean age 72±6, range 65±83 y). Data were obtained from direct measurement and ultrasonographic scans of cadaveric specimens. With the cadavers in the prone position, US scans were taken from proximal, mid-belly and distal positions of each muscle. From the recorded US images, the fascicle length, pennation angle and muscle thickness were measured. Following US imaging, the muscles were isolated and dissected from proximal to distal location in the direction of muscle fibers. Subsequently, the pennation angle and muscle thickness were measured. Bundles of fascicles were isolated and their length was measured. Two-way analysis of variance designs were used to compare fascicle length, angle of pennation and muscle thickness at matched locations in both groups. The results showed that the BF had a fascicle length of 7.50 ± 1.98 cm to 8.60 ± 2.31cm, a pennation angle ranging from 12.34 ± 2.76° to 15.03 ± 3.32° and a muscle thickness of 2.41 ± 0.41 cm to 3.58 ± 0.76 cm. The ANOVA results indicated that there were non-significant differences between US and direct measurement in all measured variables ($p > 0.05$). The results showed that the ST had a fascicle length of 17.23 ± 3.11cm to 21.58 ± 3.25 cm, a pennation angle ranging from 12.16 ± 2.98° to 14.96 ± 3.34° and a muscle thickness of 1.21 ± 0.40 cm to 2.66 ± 0.62 cm. The ANOVA results indicated that there were non-significant differences between US and direct measurement in all measured variables ($p > 0.05$). Compared with cadaveric measurements, the US variables displayed an error which is less than 5% for length measures and 3-5% for pennation angles. Pearson correlation coefficients showed a high agreement ($r > 0.90$) between the two techniques. The present results showed that determination of muscle architecture in BF and ST muscles using ultrasound is a valid technique, despite the complicated architecture of these muscles. The application of US for modeling human hamstring muscle at least under resting conditions is guaranteed.

FEMALES RUN DIFFERENT THAN MALES - IMPLICATION FOR RUNNING INJURIES?

GEHRING, D., MORNIEUX, G., FLEISCHMANN, J., GOLLHOFER, A.

UNIVERSITY OF FREIBURG

Introduction: Epidemiological studies suggest that specific running injuries occur with a higher frequency in females. Women have shown to be more prevalent to the most common running injury, the patella femoral pain syndrome (Taunton et al., 2002). As previous results suggest, that knee joint loading is deemed to be a risk factor for specific running injuries like the patella femoral pain syndrome (Stefanyshyn et al., 2006), the aim of the present study was to determine gender differences in knee joint biomechanics in experienced runners.

Methods: 3D-kinematics (Vicon) and kinetics of the knee joint were measured in 15 male and 15 female experienced runners at a running speed of 4m/s. Simultaneously, the activation of quadriceps and hamstrings muscles were determined by the use of telemetric electromyography.

Results: Females flexed their knees 5° less than males. While the males exhibited a clear knee joint adduction during the complete stance phase with peak values of 7° in average, the females showed a neutral or even abducted knee joint alignment with a peak abduction of 3° ($p < 0.001$). The maximal knee joint adduction moments were comparable between genders. However, the females had a significantly higher knee joint adduction loading ($p < 0.01$) during the braking phase, which was mainly caused by the multiple higher medial ground reaction forces than in males. Compared to males, the females' quadriceps activation was pre-shifted (about 15ms) and peaked in the braking phase.

Discussion: In accordance with previous studies females demonstrated a significant greater knee joint abduction (Ferber et al., 2003) which was combined with increased adduction moments in the initial braking phase. As frontal plane loading is associated with specific running injuries like the patella femoral pain syndrome (Stefanyshyn et al., 2006), the results of the present study may help to explain why females are more prone to this kind of injury. Furthermore, the pre-shifted quadriceps activation, related to the reduced knee flexion and therefore stiffer knee joint configuration in females, indicates that gender differences in knee joint control are even present in the sagittal plane.

RELATIONSHIP OF REARFOOT ANGULAR VELOCITY TO VERTICAL AND LEG STIFFNESS IN RUNNING

ERIKSRUD, O., ELTARVÅG, B., SMITH, G.

NORWEGIAN SCHOOL OF SPORT SCIENCES

The mass-spring model is used to describe the mechanical behavior of the lower extremity during running. At the middle of stance the spring is maximally compressed which is associated with maximal pronation, commonly described by rearfoot eversion. Few have looked at the relationship between foot motion and position to leg stiffness (Viale 1998), but not angular velocity. The current study which focuses on angular velocity was part of a larger project evaluating the influence of lower extremity joint kinematics on leg and vertical stiffness.

Methods: 15 female subjects were all tested in running along a 20 meter running path at a target speed 3.8m·s-1. Three dimensional kinematic data were obtained from reflective markers on the lower extremity using a pro-reflex motion capture system (Qualisys AB, Sweden). Three-dimensional kinetic data were obtained using three floor mounted force plates (AMTI, USA) in sequence placed midway on the runway. Three or more successful trials within a 5% range of 3.8m·s-1 were analyzed using MatLab and Visual 3D. Vertical and leg stiffness were calculated based on the method by McMahon and Cheng (1990). Rearfoot angle was calculated from tracking markers in Visual3D as the relative angle between the foot and shank segments with 0° taken as the positioning in a static standing trial. Rearfoot eversion (EvROM) was the angular change from heel strike to maximum value. EvROM was then divided by time to maximum value for rearfoot eversion angular velocity (EvAngVel). The relationship between EvAngVel and vertical and leg stiffness were evaluated using Pearsons product moment correlation (r).

Results: Mean EvAngVel was 137.9±42.78°·s-1. EvAngVel was not significantly correlated with vertical stiffness (31.8±4.7kN·m-1) ($r = -0.45$, $p > 0.05$) and leg stiffness (10.3±1.5kN·m-1) ($r = -0.46$, $p > 0.05$).

Discussion: The mass-spring model applies to the entire lower extremity as a system which collectively stores and returns elastic energy. This model does not identify which structures, joints or planes of motion that would be responsible for this. Foot kinematics is important in shock absorption during impact with the ground, and the angular velocity of foot motion could partially help explain the elastic properties of the leg-spring in running. EvAngVel was the only angular velocity analyzed, and was not found to be significantly correlated with neither leg nor vertical stiffness, however both were approaching significance (critical r=0,482). Motion in other planes, as well as other joints in the lower extremity, needs to be analyzed to better understand leg stiffness.

Conclusion: EvAngVel was not significantly correlated with neither leg nor vertical stiffness.

COMPARISON OF LOWER LIMB JOINTS LOAD BETWEEN NORDIC WALKING AND NORMAL WALKING

TAKEDA, M., KOIZUMI, T., TSUJIUCHI, N., MURODATE, Y.

INSTITUTE OF EXERCISE PHYSIOLOGY

Nordic Walking is a form of exercise born in Finland in which a walker uses a pole in each hand much like cross country ski training. Recent years have seen a worldwide increase in people participating in Nordic Walking. It has been reported that Nordic Walking has a lot of physiological effects such as higher caloric expenditure, heart rate, oxygen consumption and muscular activity particularly in arms than in normal walking1,2) with facilitate mode of exercise. For elderly people, it is desirable to have high physiological advantages with reduced lower extremity load during healthy walking. In these preliminary studies, however, the conclusions in the reducing load effects on the lower limb joints in Nordic Walking than in normal walking has been contradictory (Wilson: -4.4%, Hansen: No effect) 3,4). The ambiguity in the studies seems to be caused by their experiments conditions. In the experiments that compared for Nordic Walking and Ordinary Walking, they have controlled for the only walking speed, not for the stride length. Stride length must have the possibility to affect the load of lower limb joints during both walking.

In this study, 8 healthy male subjects performed Nordic Walking and Ordinary Walking with three walking conditions i.e., i) comfortable walking speed and stride length, ii) controlled walking speed, iii) controlled walking speed and stride length, in order to investigate the effects of reducing load at joints of lower extremity during Nordic Walking. To evaluate the knee joint load on each walking, bone-to-bone force was calculated by means of the inverse dynamic approach combining the anthropometric, kinematics and ground reaction force with body motion data of subjects measured by a three dimensional motion analysis system. In this study, it was revealed that a significantly higher value in the bone-to-bone force on the knee in Nordic Walking in comfortable walking speed and stride length i), and no significant difference in the bone-to-bone force on a walking condition in ii) and iii). On the other hand, bone-to-bone force in Nordic Walking decreased significantly accompanying with decrease in stride length under the speed level of a comfortable stride length of each subject. It has been concluded that Nordic Walking had a load reduction effect at knee with short stride length.

PROFILING ROWING RACES AND CREWS USING VISUALISATION TECHNIQUES TO ASSESS MULTI-DIMENSIONAL BOAT MOTION

DRAPER, C., TING, K.M., LIU, T., RICE, A., BUCKLEY, R.

1. AUSTRALIAN INSTITUTE OF SPORT, 2. MONASH UNIVERSITY, AUSTRALIA

Introduction: Rower, blade, boat and water are in continual interaction during the rowing stroke and must be highly coordinated to achieve international medal winning performances. Rowing is a strength endurance sport. Its continuous, cyclic and closed skill movement must be repeated more than 220 times in a race at a high strength level. Technical proficiency is essential to achieve a high performance, as it is of little value to develop strength, endurance and physiological capabilities if these qualities cannot be transferred into boat speed. As the performance gap between boats narrows (races are often won ≤0.1% over 2000m), and the training loads reach the athletes' physical limits, there is a need for further research to find new and innovative ways to help coaches and athletes improve individual racing strategies to maximise boat velocity. Measuring multi-dimensional boat performance during racing was found valuable (Draper 2008), however the data presentation lacked on profiling boat-related variables in relation to crew performances and world's best times. Therefore, the aim was to analyse racing strategies linked to the rowers' capability using visualisation techniques.

Methods: In the last three years (at World Championships, Olympics) 45 Australian boats in 18 boat categories were equipped with the MinimaxX tracking device (Catapult Innovations) during racing, collecting boat velocity, 3D boat acceleration and 3D boat orientation. The data were analysed, the stroke by stroke (sbs) data detected using proprietary software. Multi-dimensional graphical sbs time scatter

and polar plots with a defined colour scheme were used to profile performance-related thresholds or different race phases for each boat variable to assess stroke consistency patterns in relation to boat velocity.

Results: 3D time scatter plots revealed a sbs consistency of boat-related intra-stroke patterns in regards to technique, performance and race progress. Lower intra-stroke pattern variations (propulsive boat acceleration) related highly to better boat performances. Polar plots appeared more meaningful for displacement-related variables (transverse boat acceleration, yaw).

Discussion/Conclusion

Colour-coded multi-dimensional graphical displays were found to be a powerful analysis tool to profile comprehensive sbs changes of several characteristic boat-related curve patterns in relation to the sbs average boat velocity and stroke rate throughout a rowing race. The results underscored that meaningful visualisation techniques are crucial tools to assist coaches/athletes in assessing and fine-tuning racing strategies. These displays are being utilised for training and testing in optimising crew and individual technique parameters and influencing boat motion.

PS-PL02 Physical Education - Bildung or Health promotion?

PHYSICAL EDUCATION'S ROLE IN PHYSICAL ACTIVITY AND HEALTH PROMOTION

MCKENZIE, T.L.

SAN DIEGO STATE UNIVERSITY

Despite the documented benefits of physical activity, reports from around the world suggest that children and adolescents neither engage in sufficient activity for health purposes nor do they develop the appropriate skills for a lifetime of active living. The World Health Organization suggests that schools are one of the most cost effective investments a state or nation can make to improve education and health simultaneously. Additionally, physical education is the only setting where some children, particularly those from poor families, can accrue vigorous physical activity and learn important generalizable movement skills. Physical education is also one of only five interventions strongly recommended for increasing physical activity by the US Task Force on Community Preventive Service.

Physical education programs in schools have the potential to promote of healthy, active lifestyles by providing children with some of their recommended physical activity, increasing their physical fitness levels, and teaching them generalizable movement and behavioral skills. If "exercise is medicine" as suggested by the American College of Sports Medicine, physical education is indeed the pill not taken!

Numerous barriers, including limited curriculum time allocations, low subject status, and inadequate resources hinder physical education from playing a major role in providing and promoting physical activity. This paper profiles physical education as it relates to physical activity promotion, describes its current status from a contextual standpoint, and concludes with recommendations for improving it.

THE EDUCATIONAL BENEFITS CLAIMED FOR PHYSICAL EDUCATION

O'SULLIVAN, M.

UNIVERSITY OF LIMERICK

In recent years there has been growing recognition of the importance of nutrition and physical activity as key contributors to health and healthy lifestyles. This public health agenda has focussed greater attention on the potential of physical education in schools to promote active living and healthy lifestyles. Public health professionals are looking to schools as supportive environments to stem the tide of what some perceive as growing numbers of sedentary children and young people (National Health and Nutrition Examination Surveys, 2004; McKenzie, 2004, 2007; Trost, 2004; WHO, 1998). In recent years, revisions of school curriculum are reflecting a view that schools "bear a great responsibility in ensuring that children not only understand the importance of good nutrition and exercise but can actually benefit from both" (Commission on the European Communities, 2007, p.11). As one example the revision of the Primary Education in the UK seeks to drop physical education as a subject and focus on physical development, health and wellbeing (Rose, 2009). The recent foregrounding and strong advocacy of a public health agenda for physical education has created tensions (O'Sullivan, 2004) and endangered some longstanding educational benefits of physical education. This presentation will present the educational value of physical education and the evidence we have for the education impact of our subject on young people. I will highlight the current tensions between the public health and educational agendas for physical education and implications for curricular content, pedagogy, and professional preparation of physical educators.

HOW IS PHYSICAL ACTIVITY CONNECTED WITH ACADEMIC ACHIEVEMENTS AND BMI OF PUPILS

BIZJAK, K., LESKOŠEK, B., KOVAČ, M., DEBEVC, H., STREL, J.
UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

The purpose of this study was to investigate the relationship between physical activity (self-reported engagement in PE lessons and sport activity in free time of pupils has been measured), final academic achievement, math grades and body mass index (BMI) of primary school pupils, aged 11-14. Data has been collected within the research of Strel et al. (2005). Participants were 1607 pupils (nmale=841, nfemale=766) who have attended 12 primary schools in different part of Slovenia in school year 2003/04. The number of pupils in each age group and in each physical activity group was around 200. The number of pupils with the worse final academic achievement (it is measured on five grade scale) was very low (7%), that is why the bottom two grades have been combined into one group.

Ordinal logistic regression with physical activity as dependent variable, and sport activity, age, gender, academic achievement and BMI as independent variables was used to establish the factors of physical activity. After controlling for other independent variables in the model gender was found to be the strongest predictor with boys having almost two times higher odds of being physically active than girls (adjusted odds ratio AOR=1.95, p<0.001). In the sample, 28% of male and 15% of female pupils were physically active more than 9 hours per week in and out off school, while 26% of male and 38% of female pupils were physically active 4 to 5 hours per week. Physical activity increased by age (AOR=1.09, p=0.05). Pupils with lower grades tend to be less physically active but grades variables were on the border of 5% significance level (for the difference between the highest and lowest grades AOR=0.5, p=0.01 for final academic achievement).

It was found that BMI category is not associated with physical activity, no matter if this association is studied separately (Somer's D=–0.06, p=0.054) or controlled for other variables in regression model (comparing to the obese reference category AOR=0.71, p=0.19 for overweight category and AOR=0.93, p=0.76, for non-overweight category). Even though, it was confirmed that there are no differences in levels of physical activity between children and adolescent with different BMI, we cannot claim that exercise does not produce fat los because we did not measure the intensity of the activity.

THE SUCCESS OF A GENERAL SCHOOL-BASED PHYSICAL ACTIVITY INTERVENTION ON BONE MINERAL CONTENT DEPENDS ON PUBERTAL STAGE BUT NOT ON GENDER

MEYER, U., ZAHNER, L., PUDER, J.J., RIZZOLI, R., KRIEMLER, S.
UNIVERSITY OF BASEL

Background: It is not clear whether sensitivity of bone to physical loading varies for different pubertal stages and among genders. We therefore performed a randomised controlled trial in children of both gender and different pubertal stages to determine whether a school-based physical activity (PA) program during a full school-year influences bone mineral content (BMC) and whether there are differences in response for boys and girls before and during puberty.

Methods: Twenty-eight 1st and 5th grade classes were cluster randomised to an intervention (INT, 16 classes, n=297) and control (CON; 12 classes, n=205) group. The intervention consisted of a multi-component PA intervention including daily physical education during a full school year. Each lesson was predetermined, included about ten minutes of jumping or strength training exercises of various intensity and was the same for all children. Measurements included anthropometry (height and weight), tanner stages (by self-assessment), and BMC for total body, femoral neck, total hip and lumbar spine using dual-energy X-ray absorptiometry (DXA). PA was assessed by accelerometers initially, at midtime and at the end of the intervention period. Bone parameters were normalized for gender and tanner stage (pre- vs. puberty). Analyses were performed by a regression model adjusted for gender, baseline height, change in weight, average PA, post-intervention tanner stage, baseline BMC, and cluster. Researchers were blinded to group allocation. Children in CON did not know about the intervention arm.

Results: 275 (72%) of 380 children who initially agreed to have DXA measurements had also post-intervention DXA and PA data. Mean age of prepubertal and pubertal children at baseline was 8.74±2.07 and 11.13±0.60 years, respectively. 64/144 girls and 86/131 boys were prepubertal at the end of the intervention. Compared to CON, children in INT showed statistically significant increases in BMC of total body (adjusted z-score differences: 0.110; 95%-CI 0.042 to 0.178), femoral neck (0.136; 95%-CI 0.014 to 0.257), and lumbar spine (0.110; 95%-CI 0.028 to 0.191). Importantly, there was no gender*group, but a tanner*group interaction consistently favoring prepubertal children.

Discussion/Conclusion: This study shows that a general, but stringent school-based PA intervention can improve femoral neck, lumbar spine and total body BMC in elementary school children. Pubertal stage, but not gender seems to determine bone sensitivity to physical loading.

HOW TO CARRY OUT A DIAGNOSTIC TO IMPLEMENT AN INTERVENTION PROGRAM TO PROMOTE PHYSICAL ACTIVITY AT SCHOOLS – A CASE STUDY

MARQUES, A., DINIZ, J., CARREIRO DA COSTA, F.

TECHNICAL UNIVERSITY OF LISBON, FACULTY OF HUMAN KINETICS

Introduction: It is known from school intervention studies that increasing students' PE in-class activity time is an effective intervention approach to increase levels of PA among youth. What is not clear is whether different PE curricula influences long-term PA motivation and behaviour changes with the effects of personal and community influential variables taken into account.

Objectives: The purposes of this ecological study were a) to characterize both the school climate and PE curriculum (planed and in action); b) to characterize students considering: age, gender, lifestyle, attitudes toward school and PE, health and competency perceptions, achievement goals, daily routines, perceptions of his/her parents and peers PA; c) to characterize teachers', employees', and parents' lifestyle, their perceptions about both the value and aims of PE, perceptions about his/her health, past experience in PE, and about the amount of PA he/she performs.

Methods: Participants were 827 students (49.2% boys and 50.8% girls, aged 12-21 years); 72 teachers from all subjects; 38 employees; and 898 parents (419 fathers, 479 mothers). Questionnaires were used to collect data from all participants. The school principal was interviewed to determine the school politics regarding the promotion of active lifestyles. The School Educative Project (SEP) was also analysed. The quantity and quality of PA in PE classes was determined by using heart rate monitors and the SOFIT (40 students were monitored and observed during 3 lessons). The use of cluster analysis displayed different analysis.

Results: Students' overall PA was low, only 40% were considered active. The majority of the students said they commuted passively from home to school. Regarding adults, 20.9% of teachers, 13.2% of staff and 10.2% of parents were classified as active. Parents' academic background influences lifestyle. There was a closed relationship between parents' and children's lifestyle. The SEP made no mention of health or the importance of PA. Students have participated in MVPA during 58% of PE class time. There was a relationship between teachers' belief systems and their teaching practices.

Recommendations: PE accomplished its aims, and may make a more significant contribution to regular PA participation if lessons are planned and delivered with MVPA goals in mind. At school, besides PE, students can participate in scholar sports. The students' level of PA outside school was low. Because of that, an intervention program should focus mainly on educators (teachers and parents). The school must have a project to promote health-related fitness, to stimulate teachers and staff to be involved with PA, setting an example for students. This project must also reach parents, because literature shows a relationship between the PA of parents and children. Local authorities should create secure conditions for travel from home to school, and parents must motivate their children to use active transportation.

BODYWEIGHT AND MIGRATION-RELATED DIFFERENCES IN MOTOR ABILITIES IN PRESCHOOL CHILDREN "BALLABEINA"

NIEDERER, I., KRIEMLER, S., ZAHNER, L., BÜRGI, F., EBENEGGER, V., GRANACHER, U., MARQUES-VIDAL, P., PUDER, J.

INSTITUTE OF EXERCISE AND HEALTH SCIENCES, UNIVERSITY OF BASEL AND CENTRE HOSPITALIER UNIVERSITAIRE VAUDOIS (CHUV) AND INSTITUTE OF SPORTS SCIENCES AND PHYSICAL EDUCATION, UNIVERSITY OF LAUSANNE

Introduction: Motor abilities in schoolchildren have been decreasing in the last two decades (Bös, 2003, Tomkinson et al., 2003). This may be related to the dramatic increase in overweight and adiposity during the same time period. Children of migrant background are especially affected (Lasserre et al., 2007). But little is known about the relationship between BMI and migration background and motor abilities in preschool children.

Methods/Design

We carried out a cross-sectional analysis with 665 children (age 5.1 ± 0.6 years; 49.8 % female) of 40 randomly selected kindergarten classes from German and French speaking regions in Switzerland with a high migrant background. We investigated BMI, cardiorespiratory fitness (20 m shuttle run), static (displacement of center of pressure (COP)) and dynamic (balancing forward on a beam) postural control and overall fitness (obstacle course).

Results: Of the children, 9.6 % were overweight, 10.5 % were obese (Swiss national percentiles) and 72.8 % were of migrant background (at least one parent born outside of Switzerland). Mean BMI from children of non-migrant background was 15.5 ± 1.1 kg/m2, while migrant children had a mean BMI of 15.8 ± 1.7 kg/m2 (p=0.08).

Normal-weight children performed better in cardiorespiratory fitness (3.1 ± 1.4 vs. 2.6 ± 1.1 stages, p<0.001), overall fitness (18.9 ± 4.4 vs. 20.8 ± 4.6 sec, p<0.001) and in dynamic balance (4.9 ± 3.5 vs. 3.8 ± 2.5 steps, p<0.001) compared to overweight and obese children, while the latter had less postural sway (COP: 956 ± 302 vs. 1021 ± 212 mm, p=0.008). There was a clear inverse dose-response relationship between weight status and dynamic motor abilities. There were no significant differences in most tested motor abilities between non-migrant and migrant. The latter performed less well in only one motor test (overall fitness: 20.2 ± 5.2 vs. 18.3 ± 3.5 sec, p<0.001). These findings persisted after adjustment for BMI.

Conclusion

In preschool children, differences in motor abilities are already present between normal weight and overweight/obese children. However, migrant children demonstrate similar motor abilities compared to non-migrant children for almost all tests, despite their slightly higher BMI.

PHYSICAL ACTIVITY AND ITS RELATION TO AEROBIC FITNESS IN CHILDREN AND ADOLESCENTS

KOLLE, E., STEENE-JOHANNESSEN, J., ANDERSEN, L.B., ANDERSSEN, S.A.

NORWEGIAN SCHOOL OF SPORT SCIENCE

A positive relationship between daily physical activity and aerobic fitness is established in adults, but not in children. This might be caused by methodological weaknesses when measuring physical activity and aerobic fitness in children. Methods: We examined 2,299 children aged 9- and 15-years. Physical activity was assessed using the Actigraph accelerometer (4 days). Mean accelerometer counts

and time spent in moderate-to-vigorous physical activity (MVPA) and vigorous physical activity (VPA) were calculated. Peak oxygen uptake was measured directly during a maximal cycle ergometer test. Expired gas was measured with a portable MetaMax III X oxygen analyzer. Univariate relationships between physical activity and fitness variables were assessed with Pearson correlation analysis. P-values ≤ 0.05 were considered statistically significant. Results: A weak, but significant positive correlation was found between VO2peak and mean accelerometer counts in both 9-year-olds (r=0.22 for girls and r=0.24 for boys, both p<0.001) and 15-year-olds (r=0.24 for girls, p<0.001 and r=0.17 for boys, p<0.001). In 9-year-old girls and boys and 15-year-old girls, all results remained similar when VO2peak was related to minutes per day spent in MVPA and VPA. In 15-year-old boys, the correlation was somewhat stronger when VO2peak was related to VPA (r=0.24, p<0.001) only. Conclusions: Our results imply that the amount of physical activity in childhood and adolescence is associated with aerobic fitness, although weakly. Thus, as physical activity level is a factor that can be modified, it is possible to improve children's physical activity to increase their maximal oxygen uptake.

EXERCISE ATTENUATES SMOKING CUE-ELICITED REGIONAL BRAIN ACTIVATION AND SELF-REPORT CRAVINGS

JANSE VAN RENSBURG, K., TAYLOR, A.H., BENATTAYALLAH, A., HODSON, T.

UNIVERSITY OF EXETER

Introduction: Smoking cues activate the limbic brain system, a system thought to mediate the rewarding effects of addictive behaviours, and trigger urges to smoke (ie. Wilson et al, 2004). Some pharmacological treatments target neurobiological pathways to reduce cravings. Exercise reduces cigarette cravings and cue-elicited urges (Taylor et al, 2007) but it is not clear how. The aims of this study were: 1) to pilot methods to confirm the effects of nicotine abstinence and smoking images on regional brain activation; 2) to assess the effect of exercise on smoking cue-elicited regional brain activation.

Method: In study 1, on separate occasions, 7 smokers abstained for 15 hours or smoked, reported their desire to smoke, then viewed a series of (N=120) smoking and neutral images while undergoing functional magnetic resonance imaging (fMRI)(1.5T Philips Gyroscan magnet). In study 2, following overnight abstinence, 18 participants, in a randomised cross-over design, begin with either 10 mins of moderate-intensity stationary cycling or passive seating (rest). Immediately after exercise or rest, participants entered the scanner and viewed smoking and neutral images in random blocks. Desire to smoke were assessed throughout both sessions.

Results: Study 1: 'Desire to smoke' was greater after abstinence compared with smoking, F (2.3, 14.0) = 16.12, p = .00 eta2 = .729. fMRI results showed when abstinent individuals were presented with smoking related images (compared with neutral cues), there were significant activation (p = .001 uncorrected, cluster threshold 15) clusters in the dorso-medial frontal cortex, an area that receives input from regions involved in drug use motivation (orbitofrontal cortex), and the hedonic effect of nicotine (i.e caudate).

Study 2: 'Desire to smoke' was significantly lower after exercise, t= 6.81. p<.00. After rest, fMRI showed significant activations (p = .001 uncorrected with a cluster threshold of 20) when viewing smoking (versus neutral images) in the insula, the parietal lobe and the dorsal striatium (putaman and caudate). No activations were seen in the post exercise treatment, for smoking or neutral images.

Nicotine abstinent individuals experience a heightened desire to smoke and exhibit brain activation in areas associated with reward, cravings and visual attention. This is in line with previous studies (e.g. Janse Van Rensburg et al, 2009). We have shown that a single session of exercise has the ability to modulate the effects on brain activation in response to smoking cues during temporary nicotine abstinence. Thus it may be the possible neurological mechanism by which exercise may exert its effects on subjective desire to smoke.

FACTORS ASSOCIATED WITH EXERCISE REFERRAL SCHEME COMPLETION AND HEALTH OUTCOMES

MILLS, H., JAMES, D., CRONE, D., JOHNSTON, L.H., MORRIS, C., GIDLOW, C.

CANTERBURY CHRIST CHURCH UNIVERSITY

Using a population-based cohort design, an Exercise Referral Scheme (ERS) based in a diverse London borough was investigated to examine participant sociodemographic characteristics and referral reason in relation to both completion and health outcomes. Participants (n=1315) were recruited within a two-year period. The scheme was completed by 57% of participants, a body mass reduction was achieved by 33.3%, and 49.2% of participants achieved a blood pressure (mean arterial pressure) reduction.

A three-stage binary logistic regression analysis identified the factors associated with completion (stage 1), body mass reduction (stage 2) and blood pressure reduction (stage 3). The independent variables in stage 1 were participants; age, gender, ethnicity, occupation and referral reason. Completion became an additional independent variable in stage 2 and both completion and body mass reduction were added in stage 3. The regression analysis revealed that increasing age was associated with the likelihood of patients completing the scheme (Exp (β)=1.019; 1.008- 1.030; p < 0.001). Ethnicity was associated with the likelihood of completion (p < 0.05) where, in comparison to the white category, patients in the mixed category were more likely to complete (Exp(β)=6.310; 1.388-28.695; p < 0.05). Participants referred for a pulmonary condition were less likely to complete (Exp(β) =0.546; 0.346-0.860; p < 0.01) compared to those referred for cardiovascular conditions. The findings from stage 2 revealed that in comparison to the white category, patients in the mixed category were significantly more likely to achieve a reduction in body mass (Exp(β)=3.991; 1.191-13.373; p < 0.05). Those who completed were also more likely to achieve a reduction in body mass (Exp(β)=3.541; 2.721-4.608; p < 0.001). The findings from stage 3 revealed that, when compared to the unemployed category, the skilled manual category had an increased likelihood of achieving a reduction in blood pressure (Exp (β)=1.875; 1.044-3.227; p < 0.05). Participants who completed also demonstrated an increased likelihood of a reduction in blood pressure (Exp(β)= 1.680; 1.250-2.003; p < 0.001). Furthermore, those participants who achieved a reduction in body mass had an increased likelihood of achieving a reduction in blood pressure (Exp(β)= 1.292; 1.008-1.641; p < 0.05).

In conclusion, an examination of the factors associated with the scheme outcomes has indicated that some of those referred may benefit from additional strategies to encourage success (for example, younger patients and those referred for pulmonary reasons). Completion of the scheme was associated with a reduction in both body mass and blood pressure. Therefore, placing an emphasis on improving completion must continue to be a key priority for exercise interventions.

ACUTE EFFECTS OF DIFFERENT TYPES OF TRAINING ON DORSAL AND LUMBAR SPINE IN EXPERT TENNIS PLAYERS

BONAVOLONTÀ, V., FRANCIOSI, E., TITO, A., GALLOTTA, M.C., EMERENZIANI, G.P., GUIDETTI, L., BALDARI, C.

UNIVERSITY OF ROME

Introduction: Scoliosis has been found in up to 80% of athletes with an asymmetric load on the trunk and shoulders, such as javelin throwers and tennis players (Swärd, 1992). Further research found asymmetry in volume between dominant and nondominant upper limbs larger in young tennis players than in control group (Rogowski et al., 2008). Anyway it is not clear the relationship between scoliosis and the practice of tennis. In order to investigate this topic, aim of the present study was to evaluate the dorsal-lumbar spine of expert tennis players before and after two different types of training session.

Methods: The sample consisted of 10 expert tennis players (male n=6, female n=4, age 22.6 ± 1.5 years). We assessed back surface by rasterstereography analysis with Formetric® 3D System (Diers, Germany) before and after two different training sessions both lasting 1 hour and half. The first one was a standard training session and the second was a specific over-shoulder shots training session. Lordotic angle, kiphotic angle, trunk imbalance, pelvic torsion and surface rotation parameters were measured and recorded both in static (S) and in average (A) (longer interval of time) modality.

Results: In the S modality, lordotic angle was affected by type of training ($P<0.01$) and by the interaction between training and time ($P=0.05$). In the A modality, trunk imbalance and pelvic torsion was affected by time ($P=0.05$), and surface rotation significantly differed for training ($P=0.05$).

Discussion: In the S modality we found a significant difference for lordotic angle, supporting the idea that over-shoulder load leads to high stress for the spine, as it links the shoulder and the lower extremity transferring much of the ground reactive forces into the upper extremity and it is also capable of generating additional forces to the throwing motion on its own (Young et al., 1996). For the A modality, our expectation to find more differences, as the recording interval is longer, was confirmed, and we found that 2 of the 3 significant parameters (trunk imbalance and pelvic torsion) were time sensitive and did not change depending on the type of training session; this, could be related just to the load stress that is certainly higher after each training session. Instead, surface rotation was affected by the factor training session, possibly because it indicates the orientation of the spinous process rotation, and the over-shoulder shots such as service are also related to vertebral trunk rotation (Elliot, 2006).

A NEW SURVEY ON ACCIDENT RISKS AND INJURIES IN COMMUTER CYCLISTS IN BELGIUM

DE GEUS, B.

VRIJE UNIVERSITEIT BRUSSEL

The health enhancing effects of regular bicycling (e.g. commuter cycling) are well known, however this health benefit has also a negative aspect especially when safety is neglected. Bicyclists have a higher risk of being injured than any other group of road users. They are "unprotected" in traffic, despite being capable of reaching high speeds. This increases the risk and severity of the injury. Bicycle related injury statistics from police, hospital and insurance statistics are well described in many countries, but only give us details about serious or fatal injuries. In Belgium, it is estimated that only 15 to 30% of the cycling accidents are officially reported.

To overcome this underreporting, the SHAPES project conducted an internet based online injury registration study, consisting of a Retrospective (RetroSur) and a Prospective survey (ProsSur). Since injury incidence needs to be calculated not only from the number of accidents and injuries, but also from the exposure time (= time spent cycling) a prospective study was included where participants had to fill out weekly diaries for 1 year, with information on travel frequency, distance and time spend on bicycling.

During the first 10 months of online injury registration, more than 1800 participants registered on the SHAPES website. Inclusion criteria are: age between 18 - 65 years (males & females), have a paid job outside their home, cycle to work more than 2 times per week. In- and exclusion criteria for the injury registration are: accident on the route to work; acute injury; accident with corporal damage. For the RetroSur, the accident had to occur in the past 12 months before the start of the study. We present the results after 10 months data collection, during which more than 17,000 week diaries were filled out and a total of 62 accidents were considered for data analysis (ProsSur). From the 773 participants who filled out the RetroSur, 64 had an accident. The risk of having an accident while cycling to work is 8,88% for men and 6,97% for women.

The most common risk is slipping, followed by 'direct contact with a car' and 'refuse to give priority. The built-up area is the most common place where accidents happen, while the traffic was perceived as being calm. The body part that is most often injured is the knee, the hand and fingers, the shoulder. Three percent lost consciousness and 4% of the participants had a concussion. In half of the accidents, more then 1 body part is injured, with graze or bruise occurring the most often. In less than 10% of the cases the police came to the place of the accident and in only 20% of the accidents, the insurance was involved. Medical assistance was needed in 80% of the accidents, although participants were take to the hospital in only 8% of the cases.

DEVELOPMENT AND RELIABILITY OF THE TELEPHONE-BASED QUESTIONNAIRE PRISCUS-PAQ TO MEASURE PHYSICAL ACTIVITY OF COMMUNITY-DWELLING ELDERLY GERMAN PEOPLE IN EPIDEMIOLOGICAL RESEARCH

TRAMPISCH, U., HINRICHS, T., BURGHAUS, I., WILM, S., PLATEN, P.

RUHR-UNIVERSITY BOCHUM, UNIVERSITY WITTEN/HERDECKE

INTRODUCTION: There is a lack of a reliable instrument to measure physical activity (PA) of elderly people (>=70 years) for epidemiological research in Germany. The first aim of the study was therefore to develop a simple, non-invasive tool to evaluate daily habitual PA of elderly people: The telephone-based PRISCUS ("Prerequisites for a new health care model for elderly people with multimorbidity") physical activity questionnaire (PRISCUS-PAQ). The second aim was to test the reliability of the PRISCUS-PAQ.

METHODS: Validated PA questionnaires for older adults were translated and adapted to design a preliminary long version of the PRISCUS-PAQ (53 items). The questionnaire measures PA over a period of 7 days to provide a complete picture of the subject's habitual PA. It investigates different areas and periods of activity (basic everyday activity (e.g. walking), housework, gardening, sporting activities) and inactivity (sleeping, sitting) during daily life. The preliminary version was tested in 136 elderly people (aged 77±4 (71-89) years; 51% women) in a pilot study. Based on the results, the long version was adapted and shortened. To test the reliability of the PRISCUS-PAQ, the final short version (14 items) was applied to 72 community-dwelling elderly people (aged 76±4 (70-88) years; 50% women) and repeated after 4 weeks.

RESULTS: Test-retest reliability of the PRISCUS-PAQ ranged from r=.42 (walking) to r=.85 (sleeping times) as determined by the intraclass correlation coefficient (ICC). Data on habitual activity (e.g. cleaning: r=.50) were less reliable than sporting activity (e.g. cycling: r=.80).

CONCLUSIONS: The telephone-based PRISCUS-PAQ is a brief instrument for the assessment of physical activity in epidemiologic studies in older people, showing adequate repeatability in comparison to other PA questionnaires. It will now be used to collect data in a large cohort of elderly people (German epidemiological trial on ankle brachial index – getABI) within the PRISCUS research cooperation.

Acknowledgments: The study has been conducted within the research cooperation PRISCUS ("Prerequisites for a new health care model for elderly people with multimorbidity") which is funded by the German Federal Ministry of Education and Research (01ET0720).

MODERATE PHYSICAL EXERCISE IN THE ELDERLY IS LINKED TO APPROACH-RELATED EMOTIONS

VOGT, T., SCHNEIDER, S., ASKEW, C.D., STRÜDER, H.K.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: Within the recent years numerous studies connected physical exercise to changes in brain cortical activity (Hollmann and Strüder, 2003; Schneider et al., 2009). In these studies a link of physical exercise and psychological parameters is often discussed, most recently referring to the model of frontal asymmetry (Coan and Allen, 2004; Davidson et al., 1979; Petruzzello et. al, 2006). However, so far most of this research dealt with inadequate exercise intensities for the elderly and applied comparatively intricate methods. In times of an aging society health aspects in physical exercise become more and more important. Therefore it is increasingly necessary to investigate the connection of physiological and psychological elements of exercise, in particular in the elderly. According to previous research this study tends to find changes within electroencephalographic (EEG) activity and mood after a moderate intensity walk in a group of elderly subjects.

Methods: EEG on two frontal positions (Fp1 and Fp2) as well as actual state of mood was recorded before and after walking. Walking was conducted at self-selected pace for 45 to 60 min within a moderate intensity. Frontal asymmetry as a marker of approach-related emotions (Coan and Allen, 2004) was calculated using the equation (Fp2-Fp1)/(Fp2+Fp1) provided by Schutter and his colleagues (2008).

Results: Results showed effects in both EEG and mood. Within the alpha-1 frequency range (7.5 – 10.0 Hz) a significant ($p < .05$) reduction of left-lateral frontal EEG activity was found. An increase in mood was reported after walking.

Discussion: Referring to the model of frontal asymmetry, the reduction in the alpha-1 frequency range can be associated with approach-related emotions. Recent studies provide similar enhancement of mood perception due to exercise (Ekkekakis et al., 2000; Ekkekakis and Petruzzello, 1999; Schneider et al., 2009). There is reason to speculate, that even moderate physical exercise programs, as they are common for the elderly, affect a general well-being. We were able to demonstrate this by a comparatively simple and economic method.

EFFECTS OF SENSORIMOTOR TRAINING ON PATIENTS WITH MALIGNANT LYMPHOMA

STRECKMANN, F., LEIFERT, J.A., MERTELSMANN, R., KLEBER, M., BERTZ, H., GOLLHOFER, A.

MEDICAL CENTRE FREIBURG / UNIVERSITY OF FREIBURG

Introduction: Cancer patients receiving chemotherapy suffer from severe balance problems corresponding with peripheral neuropathy, progressive loss of lean muscle mass and weakness associated with a strong impairment in their quality of life. Studies have shown that sensorimotor training leads to neural adaptations that effect reflex pathways, improve proprioception and intermuscular coordination as well as the sensitivity for joint angles. The aim of this study was to improve patients' balance control, enable them to reduce the side effects of chemotherapy and improve their quality of life.

Methods: Balance control was investigated in a total of 20 patients aged 19 to 68. The patients were assigned randomly to 2 groups: an intervention group (IG) (N=10) and a control group (CG) (N=10).The IG participated in a defined sports program, containing of aerobe endurance, strength and sensorimotor exercises, twice a week. Patients were evaluated 4 times over a time period of 36 weeks: Before start of chemotherapy (T0), 12W(T1), 24W(T2) and (T3) after chemotherapy. Status of peripheral deep sensibility was evaluated by tuning fork at each test interval. Balance control following mechanical perturbation was measured on the Posturomed®. Cumulative sway paths were evaluated as well as the number of failed attempts during a bipedal mediolateral as well as bi- and monopedal anteroposterior perturbation. Static- and dynamic balance control was registered via the central point of pressure on the force plate GKS 1000. A balance pad was adjusted on top of the platform for dynamic balance measurements. Quality of Life was assessed with the QLQ-C-30 questionnaire.

Results: Patients in the IG showed significant improvement of balance control, decrease in cumulative sway paths and a highly significant reduction of failed attempts in the monopedal task on the Posturomed®. Loss of peripheral deep sensibility during chemotherapy could be diminished and the sensitivity for joint position was improved. Furthermore, the IG experienced a highly significant improvement in quality of life. In the CG, however, no improvements were shown in any of the above mentioned tests. On the contrary, they progressively declined in their cumulative sway paths and with that in their balance control.

Conclusion: Sensorimotor training is a feasible and effective method in support for cancer patients during chemotherapy treatment. The training not only improves balance and postural control but also helps to reduce discomfort from chemotherapy induced peripheral neuropathy associated with an improvement in quality of life.

METABOLIC SYNDROME IS ASSOCIATED WITH PHYSICAL ACTIVITY IN DAILY LIFE AS MEASURED USING A TRIAXIAL ACCELEROMER IN JAPANESE

KIM, J.H., TANABE, K., YOKOYAMA, N., ZEMPO, H., SATO, H., OSHIMA, Y., KAWAGUCHI, K., KUNO, S.

COMPREHENSIVE HUMAN SCIENCES, UNIVERSITY OF TSUKUBA

Introduction: The metabolic syndrome (MS) is a cluster of risk factors that predispose individuals to cardiovascular disease. Individuals with MS are at higher risk of developing type 2 diabetes and atherosclerotic cardiovascular disease, and have greater cardiovascular disease mortality rates than those without the syndrome. In Japan, MS is now a serious health problem for the middle-aged population.

Therapeutic lifestyle changes, including increased physical activity, are recommended for the prevention and treatment of MS. The effects of physical activity on MS have been examined in European and American populations, with results showing that physical activity improve the metabolic risk. However, the Japanese populations differs from European and American population in genetic background and social environment. Moreover, the required volume of physical activity remains unclear, because most investigators have either used questionnaires.

Purpose: The purpose of this study was to examine the relationship between physical activity in daily life and the prevalence of MS in middle-aged Japanese.

Methods: The subjects included 77 men and 58 women middle-aged Japanese (means±SD, 46.1±8.0 years). We measured metabolic syndrome risk factors and physical activity. The physical activity was measured for a period of 2 weeks using a triaxial accelerometer for movement registration (Omron Healthcare Co.). MS was classified using criteria modified from the National Cholesterol Education Program Adult Treatment Panel Ⅲ (NECEP-ATP Ⅲ). The relationship between physical activity and MS was assessed using logistic regression after adjustment for sex and age.

Results: A total of 31.9 % of participants has MS in this subject. The prevalence of MS was markedly lower in physically activity group compared with those who were physically inactivity group (physically activity group: 22.4 %, physically Inactivity group: 41.2 %, $p<0.05$). Total steps did not differ significantly between with and without MS. However, physical activity of ≧3 METs was significantly higher in Without MS group (without MS: 23.6±8.6 METs•h/week, with MS: 19.3±7.4 METs•h/week, $p<0.01$). Logistic regression showed that additional physical activity (10 METs•h/week, ≧3 METs) decreased the odds of MS by 0.55 (95 %CI: 0.331-0.911, $p<0.01$).

Conclusions: Physical activity was associated with lower odds and prevalence of MS, particularly in Japanese. This study suggests that to maintain level of physical activity (≧3 METs) have beneficial effects in prevention of metabolic syndrome.

THE EFFECT OF PILATES EXERCISE ON BODY COMPOSITION AND RESTING METABOLIC RATE IN DIFFERENT AGES

BAYLAN, N., PEHLIVAN, A.

MARMARA UNIVERSITY

THE EFFECT OF PILATES EXERCISE ON BODY COMPOSITION AND RESTING METABOLIC RATE IN DIFFERENT AGES

Baylan, N., Pehlivan, A. Marmara University, Physical Education And Sports, Istanbul, Turkey

Introduction: The Pilates Method is a body-mind exercise developed by Joseph Pilates, that increases muscle strength, flexibility and body awareness. Many studies have examined the effects of physical activity on resting metabolic rate(RMR) and body composition. The purpose of this study is to specify the effects of this widely popular exercise method on body composition and resting metabolic rate of women of different age groups.

Methods : The study group consisted of 64 females in total. The study group consisted of 16 females ages 40-50 and 16 females ages 18-25 . The control group consisted of 16 females ages 40-50 and 16 females ages 18-25. The study group attended a "pilates mat work" program for ten weeks, three times a week, one hour per class, while the control group did not participate in any exercise program. The subjects' resting metabolic rate was measure before and after the 10-week exercise program. The methods used were bodygem indirect method, body composition measured by bio electric impendence method, skin fat thickness measured by skinfold method, circumferences measured by measuring tape, and flexibility measured by sit and reach method. All obtained parameters were analyzed in SPSS for Windows. Results: The conclusion of the study shows that in the group of females, ages 40-50, waist to hip ratio, circumferences, and skin fat thicknesses decreased. Resting metabolic rate increased (p<0,05,) yet there were no significant change in body weight, body mass index, fat free mass, and % fat(p>0,05). In the group of females ages 18-25 there was no significant change in body composition and resting metabolic rate, but flexibility increased(p<0,05).

Discussion: Pilates improved the resting metabolic rate(RMR) in the ages 40-50 group. In the other ages 18 to 25 group there was no significant change in RMR. Former studies have shown that the amount of fat free mass effects resting metabolic rate(FFM). In this study there was no significant change on FFM, however RMR increased. Pilates exercise may have effected RMR by increasing the amount of hormone release and the amount of active cells in organs, but further research is needed. ACSM advises that cardiovascular exercise is needed 3-5 times a week for the best result on body composition. Only practicing pilates may not be enough for weight control. The results in this study confirm Segal et al's (2004) research that pilates can improve flexibility.

ENERGY COST IN YOGA

RUSTAD, S., EDVARDSEN, E.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Yoga has shown to be increasingly popular and is a common activity in many commercial training studios. Among different types of yoga, Ashtanga yoga consists of more powerful routines than the traditional yoga, and is by some instructors recommended as an effective exercise modality to loose weight and increase endurance. However, search on PubMed and Sports did not reveal any studies about the energy consumption in this type of yoga. The purpose of this study was therefore to examine the energy cost in an Ashtanga yoga class.

Methods: 10 healthy female sport students, mean age 27 yrs (SD ± 4,90), BMI 21,6 (SD ± 1,38) participated in a 60 minutes Ashtanga yoga class. Oxygen uptake (VO2) was measured about four times during the class in each subject while breathing in a mouthpiece for measurement of gas exchange and ventilatory variables. Heart rate (HR) was continuously measured and stored each 5th. second. The energy cost was calculated based on the average of the four measurements in each subject. Demographic variables and results are presented as mean values ± standard derivation (SD) or range.

Results: The mean VO2 for the whole yoga class was 14,6 ml•kg-1•min-1 (range 10,5 – 18,7) representing a METs of 4.2 (range 3,0 – 5,3). The caloric expenditure was 4,5 kcal•min-1 or 270 kcal•h-1 (range 168–348 kcal•h-1). The mean HR was 123 s•min-1 (range 88–163 s•min-1) corresponding to a oxygen pulse of 7,3 ml•s•-1 (range 5,9-10,9 ml•s•-1).

Discussion/Conclusions: Even in the subjects who achieved a high HR throughout the class, the energy cost in the Ashtanga yoga class was low, and did not fulfill the ACSM's recommendation for exercise training (300 – 400 kcal) (2). Ashtanga yoga is consideres one of the most powerful yoga-forms and our results indicate that it should not be recommended as an exercise mode for those wanting to loose weight or increasing maximal power.

RELATIONSHIPS AMONG PLASMA LEPTIN LEVEL, AEROBIC TRAINING AND RELATIVE MYOCARDIAL WALL THICKNESS IN OVERWEIGHT POSTMENOPAUSAL WOMEN

DI BLASIO, A., DI DONATO, F., D'ANGELO, E., DE STEFANO, A., GALLINA, S., GRANIERI, M., NAPOLITANO, G., PETRELLA, V., RIPARI, P.

G. D'ANNUNZIO UNIVERSITY, CHIETI

Introduction: Physiological hormonal changes accompanying menopause determine both an increase of body fat (FM%), and its shifting from gynoid to android distribution, increasing cardiovascular risk. As the main source of leptin (PLL) is FM%, PLL rise parallelly to FM% leading to leptin resistance, both broking its physiological control on feeding, and increasing the cardiovascular risk through its effects on endothelial dysfunction, hypertension, and atherosclerosis. Literature is controversial about the role of PLL on myocardial hypertrophy. If Baroulch et al. (2003) showed 4-to-6 weeks leptin infusion to reduce weight and reverse left ventricular hypertrophy, Paolisso et al. (1999) showed PLL associated with increased myocardial wall thickness in hypertensive humans. PLL has been also shown associated with hypertrophy in neonatal rat ventricular myocytes. We hypothesize that both pathologies (e.g. diabetes, hypertension), and the use of different type of cells (e.g. rat ventricular myocytes, male heart) could mislead about the role of PLL on postmenopausal heart. Aim of the study was to investigate the relationships among relative myocardial wall thickness (RWT), PLL, blood pressure and aerobic fitness in healthy postmenopausal women before and after 4 months of walking training.

Methods : 22 overweight postmenopausal women were recruited by general physicians, attesting non-hypertensive and non-diabetic condition. Body composition was assessed by multi-frequency electrical bioimpedance (Ds Medica, Italy). VO2max was estimated (VO2maxest) by Rockport Fitness Walking Test, and PLL was measured by ELISA-test. Echocardiography was performed using an ultrasound system (GE Healthcare Fairfield, CT) with a 3.7 MHz transducer. Participants walked 4 d/wk, for 50 min, at 50-60% of her HRR. Paired Sample t-Test was performed to assess variations due to walking training. Simple regression models were performed both on basal and post-intervention values to quantify the effect of FM%, VO2maxest, PLL and diastolic blood pressure (DBP) on RWT.

Results: Participants were hyperleptinemic (34.98±16.70 ng/ml) and had a fair VO2maxest (25.75±3.71 ml/kg/min). Walking training determined a reduction of FM% (p=0.008), PLL (p<0.001) and RWT (p=0.03) and an increase of VO2maxest (p<0.001). Basal regression

model indicated the predictive role of PLL (coeff. est.=-0.002, t=-2.353, p=0.03) and DBP (coeff. est.=0.003; t=2.241, p=0.04) on RWT. After the training, regression model had no statistical significance.

Discussion: Light hyperleptinemia, without confounding variables, could be protective by myocardial hypertrophy in unfit postmenopausal overweight women. The positive contemporaneous modification of RWT, FM%, PLL and VO2maxest, elicited by the aerobic training, did not allow to indicate one or multiple protective factors at the end of the study.

STRENGTH, MUSCLE QUALITY AND FUNCTIONAL CAPACITY IN LIVER TRANSPLANTED FAMILIAL AMILOIDOTIC POLINEUROPATHY PATIENTS.

TOMÁS, M., SANTA-CLARA, H., MONTEIRO, E., PIMENTA, N., CABRI, J., FREIRE, A., BARROSO, E.

FACULDADE DE MOTRICIDADE HUMANA; LISBON HIGHER SCHOOL OF HEALTH TECHNOLOGY,POLYTECHNIC INSTITUTE OF LISBON; HOSPITAL CURRY CABRAL; SPORT SCIENCES SCHOOL OF RIO MAIOR, POLYTECHNIC INSTITUTE OF SANTAREM

Introduction: Liver transplantation is the unique treatment for several end stage diseases. Familial Amiloidotic Polineuropathy (FAP) is a neurodegenerative disease related with systemic deposition of amyloidal fibre mainly on peripheral nervous system, clinically translated by an autonomous sensitive-motor neuropathy with severe functional limitations in some cases. The unique treatment for FAP disease is a liver transplant with a very aggressive medication to muscle metabolism and force production. To our knowledge there are no quantitative characterizations of body composition, strength or functional capacity in this population. The purpose of this study was to compare levels of specific strength (isometric strength adjusted by lean mass or muscle quality) and functional capacity (meters in 6 minutes walk test) between FAP patients after a liver transplant (4.1±2 months after transplant surgery) (FAPT) and a healthy group (HG). Sixty-four subjects where assigned in 2 groups: 46 patients FAPT (27 males, 32±8 yrs; BMI 21.8±3.8 and 19 females, 37±5 yrs; BMI 22.4±4.0) and eighteen HG (9 male, 34±7 yrs; BMI 24.3±1.8 and 9 female, 36±8 yrs; BMI 23.2±2.6). Isometric strength of quadriceps was measured using an isokinetic dynamometer (Biodex). Body composition was determined by measuring lean mass of dominant lower extremity in a region of interest (thigh) by dual-energy x-ray absorptiometry. Muscle quality was ascertained by taking the ratio of strength to muscle mass. Results: HG showed significant higher values than FAPT patients for: peak torque (66.3N±25.2N vs 40.2N±17.6N respectively p=.000), muscle quality (11.8±2.6 vs 7.9±2.7 respectively, p=.000) and functional capacity (675.8m±109.1m vs 511.4m±139.1m respectively, p=.000). There are no differences between HG and FAPT for BMI (23.8±2.2kg/m2 vs 22.0±3.8 kg/m2 respectively, p=.07) and thigh muscle mass (5.5kg±1.2kg vs 5.05kg±1.1kg respectively p=.14). Negative correlations were observed for FAPT patients but not for HG between age and peak torque (p=.013; r=-.363) and age and thigh muscle mass (p=.011; r=-.373). When comparing functional capacity, peak torque, muscle quality and thigh muscle mass between males and females in each group significant higher values where observed (p≤.05) in males for HG but these differences disappeared in FAPT patients with exception for thigh muscle mass (p=.000; 5.6kg±1.02kg vs 4.3kg±0.7kg for males and females respectively). Conclusions: FAPT patients have lower functional capacity, strength and muscle quality than HG. The differences between groups for muscle quality and peak torque but not thigh muscle mass seems highlight the importance of the neural component of the disease and show also the importance of training the process of force production specially the sensoriomotor component in FAP patients and probably the importance of a strengthening exercise program. Further studies are needed to explore training effects on function after transplantation.

COMPARISON STUDY OF MATERNAL HEART RATE OF LAND/WATER ACTIVITIES IN LATE PREGNANCY

CORDERO RODRÍGUEZ, Y., BACCHI, M., PELAEZ FUENTE, M., LÓPEZ MAS, C., BARAKAT CARBALLO, R.

TECHNICAL UNIVERSITY MADRID

INTRODUCTION: Many pregnant women wish to engage in aerobic exercise during pregnancy but are concerned about possible adverse effects on the outcome of pregnancy. In recent years there has been a great increase of scientific research regarding physical exercise during pregnancy and the pregnancy outcome (Barakat et al, 2008. Barakat et al, 2009). Nevertheless, many doubts persist relative to the response to exercise by the pregnant woman. Limited information is available about the comparison of the type of exercise (land-water) and the maternal response. Our aim was to assess and to compare maternal heart rate during land and water exercise of the same intensity level.

MATERIAL AND METHODS: 15 healthy pregnant women (nulliparous) at third trimester were evaluated (mean of gestational age=245 ± 14.3 days). Other maternal data were recorded including parity, smoking, occupational activity and physical activity habits. The physical activity protocol consisted of a session of aerobic exercise (25 min), the intensity of activity was evaluated by Borg Scale (level 12=light), maternal heart rate was registered by Polar F6 model. Aquatic session of similar intensity was developed and maternal heart rate was registered also. Comparison of data of maternal heart rate was made by Student t Test.

RESULTS: Our results shows that exercise developed on land produce larger elevations (mean: 110,86±6,1) in maternal heart rate than water activities (mean: 105,40±6,1) at same level of intensity, although no significant differences were found (p=0.09).

DISCUSSION: The aim of our study was to compare the effects of land and water exercises during pregnancy. O´Neill et al. (1992) studied the accuracy of Borg's ratings of perceived exertion in the prediction of heart rates during pregnancy but they didn't include aquatic exercises. In our opinion maintenance of the corporal weight caused by the pregnancy is possibly the cause of these differences, naturally during the aquatic activities this extra corporal weight caused by the pregnancy is attenuated (Granath et al, 2006).

TYPE OF DELIVERY IS NOT AFFECTED BY LIGHT RESISTANCE AND TONING EXERCISE TRAINING DURING PREGNANCY: A RANDOMIZED CONTROLLED TRIAL

BARAKAT CARBALLO, R., PELAEZ, M., RUIZ, J., STIRLING, J., ZAKYNTHINAKY, M., LUCIA, A.

TECHNICAL UNIVERSITY MADRID

Introduction: Obstetricians lack sufficient information for providing constructive guidance for patients who want to be physically active during their pregnancies. One frequently asked and important question regards the possibility that physical activity, especially during the second part of pregnancy, might affect gestational outcomes, such as type of delivery. We examined the effect of light exercise training performed throughout the second and third trimester of pregnancy on the type of delivery, as well as on the dilation, expulsion and childbirth time.

Methods: 160 sedentary women were randomly assigned to either a light intensity resistance and toning exercise training group (n=80) or a control group (n=80). Several maternal and newborn's characteristics, were recorded including the type of delivery (normal, instrumental, or cesarean) and dilation, expulsion and childbirth time.

Results: The percentage of women having normal, instrumental or cesarean delivery was similar for both the training (70.8%, 13.9% and 15.3% respectively) and control groups (71.4%, 12.9% and 15.7% respectively). The expulsion, mean dilation and childbirth time did not differ between groups.

Discussion: Certain scientific evidence has demonstrated that physical exercise during pregnancy does not have adverse effects (Barakat et al, 2008, 2009). In that sense, our results showing no differences in the type of delivery between both groups are in apparent disagreement with previous data from prospective (Bungun et al, 2000. Clapp, 2008) or training studies, which suggests that regular exercise performed over the course of pregnancy is associated with increased incidence of vaginal delivery (Hall & Kaufmann, 1987) . Comparisons between studies are difficult to make owing to differences in several variables that can affect type of delivery such as age, body mass index, gestational weight gain age, previous parity history, smoking habits, alcohol intake, number of hours standing or epidural anesthesia. In conclusion in we found that light intensity resistance and toning exercise training performed over the second and third trimester of pregnancy does not affect the type of delivery.

DIFFERENCES IN SOMATOTYPE AND THE LEVEL OF SUBCUTANEOUS FAT TISSUE AMONG PHYSICALY ACTIVE AND INACTIVE WOMEN

STOJILJKOVIC, N., PANTELIC, S., SAVIC, Z., JOVIC, D.

FACULTY OF SPORT AND PHYSICAL EDUCATION, UNIVERISTY OF NIS

Introduction: Today there are a great many physical exercise programs designed for women, which lead to changes in body composition (Donnelly et al., 2003). The aim of this paper is to determine the differences in the level of one of the components of body composition between physically active and inactive women, primarily fat tissue and to determine whether a physical exercise program can lead to a change in somatotype.

Methods: Our study included 59 women aged 23 (±3 months), 29 of which were physically active (PA), and 30 physically inactive (NA). The PA women were included in a 12-week physical exercise program, and the NA women did not take part in any kind of physical activity. The level of fat tissue was determined by means of bioelectric impedance (Baumgartner, 1996) and with the help of a Body Composition Monitor TANITA UM-72. The Carter & Heath (1992) method was used to determine the type of somatotype. Statistical analyses were used to determine the differences in results from the initial and final measurings of each group.

Results: The groups of PA and NA women were characterized as having meso-endomorphic traits both at the initial and final measuring (PA initial 4.6-4.2-2.1; PA final 4.1-4.0-2.5 / NA initial 4.2-3.7-2.5; NA final 4.1-3.6-2.5). For the PA group, no statistically significant differences were found between the results of the initial and final measuring ($p > .05$), even though a decrease was noted in the endomorphic and mesomorphic components, while a statistically significant decrease in the values of fat tissue were noted ($p < .01$). No statistically significant differences were noted during the two measurings of the members of the NA group, either in terms of somatotype or in the values for subcutaneous fat tissue.

Discussion: The conclusion of this paper is that physical exercise program which lasts for 12 weeks can lead to changes in the subcutaneous fat tissue, but cannot lead to changes in the somatotype of physically active women.

PEAK OXYGEN CONSUMPTION AND LEPTIN, ADIPONECTIN, HDL CHOLESTEROL, PAI-1 OR APO-A IN YOUNG FEMALE ATHLETES

YAMADA, A., NAKAMURA, M., TANAKA, S., YAMAMOTO, S., AIZAWA, T., NAKAMURA, T., MATSUMOTO, H., KITAJIMA, M., MEREN, J., KASHIZUKA, S.

MUKOGAWA WOMWN'S UNIVERSITY

Introductions

Lifestyle related diseases as diabetes mellitus, hyperlipidemia or arteriosclerosis are closely related to their secretion level of the leptin, adiponectin and also related to concentration of HDL cholesterol, PAI-1 or APO-A. It is well known that persistent low level of exercise activity brings abnormality of serum concentration of adipocytokines, HDL cholesterol, PAI-1 in studies of middle or older ages, however little are known in young females. So in this study, we evaluated the exercise capacity, body composition with DEXA, and we studied serum level of adipocytokines, HDL cholesterol, PAI-1 and APO-A in female students in university.

Methods: We examined serum sampling in 67 normal young athletic women early in the morning. The measurement of peak oxygen consumption was performed by breath by breath using gas analyzer and monitored a heart rate with treadmill running. The body composition was also measured with DEXA.

Results: It showed an positive correlationship between peak oxygen consumption and adiponectin or APO-A or HDL-cholesterol and showed a negative correlationship between peak oxygen consumption and leptin or %fat or PAI-1.

Discussion: Adiponectin is one of the important molecules to inhibit the development of atherosclerosis and plasma high density lipoprotein-cholesterol levels are also inversely correlated to the risk of atherosclerotic cardiovascular diseases. ApoA-1-mediated cholesterol is increased by adiponectin secretion. APO-A or adiponectin same as HDL-cholesterol is of use to evaluate training effects in young females. Metabolic syndrome is associated with higher levels of leptin, PAI-1and with lower levels of adiponectin. It can be suggested that there was a possibility to evaluate the presence of having habitual exercise in young female to examine serum level of leptin or PAI-1

THE MORPHOFUNCTIONAL CONDITION OF ADULT WOMEN IN RELATION TO PHYSICAL ACTVITY

SLAWINSKA, T., IGNASIAK, Z., ROZEK, K.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION

Introduction: The way of spending one's spare time and many daily habits are the elements of human behaviour which constitute a certain lifestyle. In case of adults the assessment of physical activity concerns not only the activity during spare time, but also during work. Physical activity which is undertaken for the proper amount of time and with regular frequency generally has a positive influence on the functioning of human organism, regardless of one's age. The aim of this work is to assess the somatic and functional parameters of adult women and to study if the values of these parameters are changed by active lifestyle.

Method : 132 women aged 25 – 65 were examined. They were divided in two groups: the younger one (25 – 49 years) and the older one (50 – 65 years). The following measurements were taken: body height and mass, body composition (fat mass, lean body mass, water), lungs' ventilation parameters (VC, FVC), and motor fitness (hand-grip strength, flexibility). BMI was calculated. The Seven-Day Physical Activity questionnaire was carried out (1997, 2003). The results regarding the time spent on physical activity, working with computers and watching television and a self-assessment of one's wellbeing were used in the study. Basic statistical characteristics and regression equations were calculated.

Results: The older women are characterised by a significant rise of body mass caused by an increase of the total amount of fat in the organism with no change of lean body mass. The systolic and diastolic blood pressure rises, however pulse remains at the same level as in younger women. In the older group a significant decrease of hand-grip strength, flexibility and lungs' ventilation parameters (VC, FVC) is observed. The older women spend less time on physical activity and more on watching television. The observed decline of biological condition reflects in health self-assessment.

After comparing the groups of women taking exercise and not taking exercise at all it has been stated that physical activity has contributed to the improvement of somatic and functional parameters of younger women. It is possible that older women did not spend enough time on physical exercise to see its positive effects.

INFLUENCE OF HEAT PRECONDITIONING ON ECCENTRIC CONTRACTION-INDUCED MUSCLE DAMAGE AND MUSCLE SORENESS IN WOMEN.

SAGA, N., IMAI, H., KAI, F., KATAMOTO, S., NAITO, H., SAKURABA, K.

INSTITUTE OF HEALTH AND SPORTS SCIENCE & MEDICINE, JUNTENDO UNIVERSITY

Introduction: Strenuous eccentric exercise induces skeletal muscle damage and delayed-onset muscle soreness (DOMS). Recently, we have reported that heat treatment at one day before eccentric contractions could inhibit muscle damage in men. However, a previous study suggests that there may be gender-based differences in skeletal muscle responses to eccentric contraction-induced muscle damage. Therefore, the purpose of this study was to examine the influence of heat preconditioning on eccentric contraction-induced muscle damage and muscle soreness in women.

Methods: Nine untrained female subjects (23 ± 3 yrs) volunteered to participate in this study. They were randomly assigned to with (HEAT; n = 5) or without (CON; n = 6) heat preconditioning group and were asked to perform 30 repetitions of maximal isokinetic eccentric contractions (ECC; 10 reps × 3 sets) of non-dominant elbow flexors at angular velocity of 30°･s-1 by means of isokinetic dynamometer. The heat preconditioning was achieved by microwave hyperthermia units (150 W, 20 min). Maximal voluntary isometric strength, range of motion of elbow joint, upper arm circumference, serum creatine kinase (CK) activity and muscle soreness were assessed for 4 days after ECC. Maximal voluntary isometric strength was measured twice for 5 s at an elbow angle of 90°. Range of motion

was assessed as an angular displacement from relaxed through flexed positions. Upper arm circumference was assessed by the tape measurement of five points (3, 5, 7, 9, 11 cm above the elbow joint) on the upper arm in relaxed position. Approximately 10 ml of blood sample was drawn by venipuncture from the cubital fossa region of the arm for serum CK activity. Muscle soreness was measured using 100-mm visual analogue scale.

Results: The reductions in maximal voluntary isometric strength and range of motion of elbow joint were not changed by heat preconditioning (HEAT: 54 ± 14 % vs. CON: 51 ± 6 %, HEAT: -24.3 ± 15.5° vs. CON: -21.8 ± 13.8°). Also, Heat did not show any significant changes in the upper arm circumference (HEAT: 0.7 ± 0.4 cm vs. CON: 0.5 ± 0.3 cm), CK (HEAT: 349 ± 344 U/L vs. CON: 1878 ± 1092 U/L) and muscle soreness (HEAT: 45.5 ± 12.4 mm vs. CON: 67.6 ± 24.2 mm) after ECC, compared with CON.

Conclusion

These results suggest that a heat preconditioning at one day before eccentric contractions could not affect the eccentric contraction-induced muscle damage and muscle soreness in women.

AGE AND SEX DIFFERENCES IN PHYSICAL ACTIVITY OF STUDENTS LIVING IN THE LISBON METROPOLITAN AREA

MARQUES, A., DINIZ, J., CARREIRO DA COSTA, F.

TECHNICAL UNIVERSITY OF LISBON, FACULTY OF HUMAN KINETICS

Introduction: Despite the knowledge of benefits of regular physical activity (PA), some studies with students have shown high prevalence on sedentary habits. Because of this it is important to investigate the determinants of their PA participation.

Objective: This study sought to examine sex and age differences in PA among students of 12, 15 and 18 years, living and studying in the Lisbon metropolitan area. It also characterizes adolescents' lifestyles and their psychological background.

Methods: A total of 877 students (436 boys, 441 girls) ages 12 (n=250), 15 (n=550) and 18 (n=77), from six public schools in Lisbon were sampled. Data was collected using a questionnaire about leisure time activities, PA participation, goal orientation, perceptions of health, competence and body image. A PA index was produced from questions about sports participation in several contexts (formal, informal, school sport, and intensity of PA during the week). An ANOVA and Scheffe post hoc comparisons to analyze the effects of age and sex on the PA index were used. Values were considered significant at $p < 0.05$.

Results: The mean of the PA index was 3.02±1.10 (3.27±1.05 for e 2.78±0.96 for girls), ranged between 1 and 6. A tendency to decrease the PA index by age in both sexes was observed. The general effect of age on PA index was significant with high intensity ($F(2,871) = 4.617$; $p = 0.01$; power = 0.78). Statistical differences were found between 12 and 18 years; 15 and 18 years, in both sexes. Even though 12 year old students were more active than 15 year olds, ANOVA revealed no significant differences.

Comparing sexes, boys had higher levels of PA participation than girls in all age groups, verifying that the lowest levels of boys, at age 18 (2.93±1.14), were superior to the highest levels of girls, at age 12 (2.82±0.92). It was very interesting to observe that girls ages 12 and 15 participated more than boys in school sport. Nevertheless, this tendency changed by the age of 18. Participation in PA decreased with age in both sexes. The general differences between boys and girls were significant ($F(1,871) = 28.074$; $p < 0.001$; power = 1).

Conclusions: The mean PA index was relatively low in general for all students but especially for girls. These results are in line with results that were obtained by other national and international studies. Something must be done in order to prevent this reality. The fundamental role that schools and PE can assume in the promotion of active lifestyle has been largely recognised. This claim must be assumed by school community. The older students and girls should be the focus of specific interventions. After leaving school they will no longer be obligated to participate in PE classes, which could mean that their PA levels will drastically decrease.

EFFECTS OF THE MENSTRUAL CYCLE ON EXERCISE PERFORMANCE IN ACTIVE WOMEN

KHOSRAVI, N., ABDOLLAH POOR, A.

ALZAHRA UNIVERSITY

The present study examined the effects of menstrual cycle on exercise performance in university active women. Method: Fourteen active eumenorrheic women (age 21 ± 1.8 yr) after to fill up questionnaire was selected randomly. After determination the phases of menstrual cycle, subjects were performed a graded maximal exercise test for two phases of follicular (days 7-11) and luteal (days 19-23).The body fat(fat%),weight and height assessed before test .Blood lactate, VO2max, time to exhaustion, estrogen and progesterone hormones were measured in the FT and LT phases. Rating of perceived exertion assessed by Borg scale . Results :The results showed no significant differences between the follicular and luteal phases in VO2max (31.26 ± 3.01& 30.41± 3.43 ml.kg¹ֿ.min¹ֿ respectively), blood lactate ,maximal heart rate , time to exhaustion, and rating of perceived exertion (p>0/05).In addition ,there was no significant correlation between VO2max and progesterone hormone in the luteal phase (r =-./25, p>0/05).Conclusion:Data suggest that normal cyclic variations in estrogen & progesterone are without significant effect on any measure of maximal exercise performance. We conclude that in this study , menstrual phase (follicular vs luteal) with menstrual status (eumenorrheic) no alters or limits exercise performance in female active.

LEPTIN AND PHYSICAL FITNESS IN POSTMENOPAUSE

D'ANGELO, E., DI BLASIO, A., RIPARI, P., DI DONATO, F., GALLINA, S., PETRELLA, V., VALENTINI, P., NAPOLITANO, G.

G. D'ANNUNZIO UNIVERSITY, CHIETI

Introduction: A big amount of postmenopausal women is overweight. Excessive body fat (FM%), especially when centrally distributed, is associated with an increased risk to develop diabetes, coronary heart disease, hypertension, ischemic stroke and several cancers. As adipose tissue is the main source of plasma leptin levels (PLL), FM% increases PLL up to leptin resistance, breaking its healthy physiological function (Considine et al., 1996). As PLL is related both to cardiovascular risk factors (e.g. endothelial dysfunction, hypertension, atherosclerosis) and risk of cancers, independently of FM%, it is highly suggested to reduce high PLL. The aim of this study was to investigate the effect of regular walking training on PLL in 22 overweight postmenopausal women.

Methods: Body composition was assessed by multi-frequency electrical bioimpedance (Human-Im PLUS, Ds Medica, Italy) and data were processed by software Human-Im PLUS 4.0. Dietary habits and caloric intake were estimated by a dietician with three-day dietary records, covering two weekdays and one weekend day, using WinFood-due software (Medimatica, Colonnella, Italy). VO2max was estimated (VO2maxest) by Rockport Fitness Walking Test and PLL was measured by commercially available ELISA-test. No dietary suggestions were given. Each woman walked 4 times a week, for 50 min, at 50-60% of her heart rate reserve.

Results : Walking training determined a decreasing FM% and PLL and an increasing VO2maxest. No variations in dietary habits were reported. Basal values of VO2maxest were poor. Multiple regression models were performed, both on basal and post-intervention values, in order to understand if walking training affected positively PLL taking under control FM% and energy intake. VO2maxest was taken as a proxy variable for walking training effect. Results indicated that, under basal condition, FM% was the only predictor of PLL (coeff. est.=1.093; p=0.010). Furthermore, after the training, FM% and VO2maxest had respectively positive and negative influence on PLL (coeff. est. FM%=0.779, p=0.007; coeff. est. VO2maxest=-1.092; p=0.003).

Discussion: Our results increase the assumption that, independently from FM%, aerobic fitness improvement affects positively PLL in postmenopause, as shown in young women (Hickey et al., 1997). This could lead to a reduction of both leptin resistance and negative cardiovascular effects of leptin even if body composition is not bettered.

HENRIK IBSEN AND THE ORIGIN OF FRILUFTSLIV. AN OCCASION FOR CELEBRATION.

LEIRHAUG, P.

UNIVERSITY COLLEGE OF SOGN OG FJORDANE

Introduction: In 2009 it is 150 years since Henrik Ibsen wrote Paa vidderne, translated as On the Heights (alternative translations: Life on the Upland; On the Mountain Wilderness). In this long epic poem, he probably introduced in print for the very first time the word 'friluftsliv'. Did Ibsen create the word? It is hard to tell. But in the meantime friluftsliv has become an important word in the Norwegian language and culture as well as a theme at international scientific congresses. In addition Henrik Ibsen has become one of the very greatest names in world literature. Despite these facts few attempts have been made to investigate possible meanings and functions of friluftsliv" in Ibsen's poem.

Methods : Literary analysis and interpretations.

Results/Discussion: Most translators have treated 'friluftsliv' as a specific Nordic term. The consequence for English readers of On the Heights of course, is that the word 'friluftsliv' just isn't there. Either it is simply translated to 'outdoor life', or the passage is somehow rewritten. Here after Reed and Rothenberg (1993:12):

In the lonely seter-corner,
My abundant catch I take.
There's a hearth, and a table,
And friluftsliv for my thoughts.

The poem in total consists of 328 lines. We follow a young nameless man who leaves his home and the girl whom he loves, and heads for the mountains. First his plan is to return, with a splendid reindeer pelt for his mother, and some too for his sweetheart. But then he meets a stranger urging him to stay. The winter comes. At Christmas he observes the house in the valley burn to the ground with his mother inside, and by summertime his sweetheart is another's bride. The young man fills with sorrow, but at the same time it becomes obvious that there is nothing left for him down in the valley. He has expended his "lowland life" and the poem ends. This short summary and the quotation above actualises several underlying themes that can have relevance to our modern understanding of friluftsliv: to be alone in nature; a life simple in means, but maybe rich in ends; connections between friluftsliv and activities of more intellectual, recreational or spiritual character. It should be emphasized how the young man has to make deep sacrifices in order to achieve "the higher view". His "bosom becomes as stone". In the end he is "steel-set" and follows a command to live on the hills. Friluftsliv is introduced at an earlier stage in Ibsen's poem and does not belong to this extreme idealism. In "friluftsliv for my thoughts" the main character still has contact with the everyday ordinary life.

THE EMBODIED SOLDIER: TOWARDS A NEW SOLDIER ETHOS FOR THE MODERNIZED NORWEGIAN ARMED FORCES?

SOOKERMANY, A.

NORWEGIAN SCHOOL OF SPORT SCIENCE

The military transformation of the armed forces is changing our understanding of what are good soldiering skills. The modernization process aims to develop military communities of practice that are ready, willing and able to serve and fight anyone, anywhere, anytime on regular bases. As a consequence many western countries, like Norway, are witnessing a radical shift from conscription towards professionalism – were being a soldier should be understood as an embodiment of the knowledge, skills and values of a professional military community of practice. In this article I will explore how the thinking underpinning the traditional invasion defense force and the flexible expeditionary force of the future supports two different views of the human body. In doing so I will show how a change from a traditionally dualistic view towards a more integrated holistic view can offer an opportunity to transition from competent, good enough practice to expert practice – and thereby a new soldiering ethos.

Keywords: transformation; soldiering skills; military community of practice; the emdodied soldier; soldier ethos

ANALYSIS OF RISKY BEHAVIOURS AMONG YOUNG BRAZILIAN ATHLETES

RUBIO, K., NUNES, A.V.
UNIVERSITY OF SÃO PAULO

The substances use and other ergogenics use by young and experienced athletes are common. Searching for an outstanding performance, the greed most of the times comes without essential ethical cares. This project has as objective the investigation of what's the athletes knowledge level when they are in the basis categories (12-14 years old), considering the ergogenics sources that are considered doping, or not. What is the motivation for them to the sportive practice and which are the factors or who are the people that influence their decision. Besides, it is intend to identify how act, in relation to this matter, the others agents so as: the coaches, the physical trainers, the medical team, the sportive psychologists and the team managers. The methodology insight the preparation of three investigation procedures: the behavior observation, made through athletes' films got during and as soon as the competition is finished; behavior analysis of athletes' and coaches', made through some application forms and trough a personality given test. The questionnaires (forms) will be given to all of the participant population on the Brazilian School Olympic Games in 2009, 2010 and 2011, including athletes, coaches and delegation managers. The personality test will be given as the sample calculus points out.The observations will be made in winners of the event, representatives of the five sport groups: strength and speed, resistance, collective games, combat sports and technique sports.The evaluations will be made during the Brazilian School Olympic Games (OEB) on the three years of 2009, 2010 and 2011 on the athletes' class (12-14), in all of the modalities.These athletes represent all Brazilian regions. The Brazilian Sport Ministry joined to the Brazilian Olympic Committee is promoting this event.This generation athletes should represent the country on future international events, and it's highly risky in the matter of the substances or methods potentially harmful to their health, which may be considered doping. At this age, the athletes begin to subdue to high train levels and they aren't controlled about the risk of prohibited substances or not. At this social group, it seems to be important the prevention to the use of social drugs and the use of drugs that increase performance. Coaches and multidisciplinary teams probably lead an important roll on the decision of these athletes and they may contribute to the correct ethical make up, or not. It is intend to analyse the kind of repercussion that the research can bring to these athletes and their own origin places, because this project treat of young athletes originated from the most different country localities and they, most of the times, return to the event on the next year. This investigation must create a national program of conscientiousness related to the use of social drugs and that increase performance. The study has the Sport Ministry and the Brazilian Doping Combat Agency guarantee to be realized.

ATTITUDES AND VALUES OF TALENTED YOUNG ATHLETES TOWARDS PERFORMANCE ENHANCING DRUGS: A QUALITATIVE STUDY

MCNAMEE, M., BLOODWORTH, A.
SWANSEA UNIVERSITY

USA-based review articles suggest a small but significant proportion (between 3 and 12 per cent) of adolescent males have used anabolic-androgenic steroids (AAS) at some point (Calfee and Fadale, 2006; Yesalis and Bahrke 2000). There are suggestions, however, that the terminology used in some questionnaires has lead to over estimates of prevalence (Kanayama et al., 2007). The general problem of doping in adolescents and young people has rarely been addressed in depth using qualitative methods. In this study a total of 40 talented young male and female athletes (mean average age 19.6 years) from 13 different sports attended 12 focus groups held over the UK in both 2008 and 2009.

Athlete knowledge of doping techniques was generally limited, as was their access to populations among whom doping or pharmaceutical body enhancement was practiced recreationally. Elite athletes often trained only with each other at elite facilities, and were in the main insulated from the wider trend toward body enhancement for aesthetic reasons noted within the health and fitness community more generally (Baker, Graham and Davies, 2006). Athletes in general did not report a significant national doping problem in their sport, but were sceptical regarding both doping practices and the stringency of testing procedures outside the UK. The traditional moral emotions of shame and guilt associated with doping were cited as significant deterrents (for a discussion of shame in relation to doping see McNamee, 2008). Athletes in general perceived no pressures to use performance enhancing drugs. In hypothetical discussion various factors were acknowledged as potential 'pressure' or 'tipping' points: most notably the economic pressures of elite sport. Finally, a significant minority of athletes entertained the possibility of taking a hypothetical, banned but undetectable performance enhancing drug that would guarantee success. When a caveat was added to the hypothetical question that this drug would reduce life span by ten years it resulted in an almost total rejection of the possibility of doping. The study thus offers an insight into the values and attitudes of young athletes, extending beyond mainly survey based research concerning doping prevalence.

SPORT AND CHRISTIANITY: SIMILES AND RECIPROCAL INFLUENCES OF TWO PILLARS OF WESTERN CULTURE

SCARPA, S.
UNIVERSITY OF PADUA

Sport and Christianity are two phenomena which have remote origins: the first was born in Ancient Greece, the second has established itself within the Jewish culture as a point of rupture and progress compared to the previous tradition. Both have influenced each other reciprocally in many occasions through the contact between the original cultures. Both of them have evolved in time until they reached today a mass distribution on the entire planet, characterizing themselves as two of the pillars of western culture.

We can find an initial example of the reciprocal influences between Hellenic culture and Jewish-Christian culture in the ascesis, a practice shared but not invented by the Christians. Ascesis is a word coming from the world of Greek sport. The sportsman trains in order to

achieve outstanding performances. From the sports world, the word moved to the sphere of philosophy. Philosophers trained in order to achieve inner freedom. Furthermore, in San Paulo, sport is considered as metaphor of Christian life. This parallelism between Christian values and sports ethics is afterwards spoken about again by some Fathers of the Church and it has remained alive also during the Contemporary age, as it is possible to notice in the numerous « speeches » pronounced by the last Popes.

A line of circularity and fruitful reciprocality with Christian thinking appears by analyzing the foundations and the values which characterize sport. Values such as honesty, solidarity, loyalty, perseverance, altruism, peace, justice, fortitude, self-control, wisdom etc… are expressed through sport. Sport is joy of life, play, fun. All the factors that constitute the strong cultural, ethical and educational valence, which materializes itself in creating development and permanent growth opportunities of man in the totality and truth of its values and its needs. Sport is expression of the richness of the human being, much more valid and appreciable than having, and therefore much above the severe production and consumption laws and every other life consideration that is purely utilitarian and hedonistic. There is an ethical crucial need that conscience knows not to delete: that of turning sports practice into a reality which services the person, in the totality of his values and necessities. It is the evangelic and at the same time rational principle: «not man for sport, but sport for man».

Sport, as an educational vehicle with wide spread diffusion, is on the same wavelength of the Christian message for the same reason that the essence of real sport shares the majority of Christian values and its practical dimension allows to stage, in real terms, the «game field» in which those values can be reached.

PP-SP01 Sport Management

SPORT FAN IDENTIFICATION, PERSONALITY TYPE AND SPORT CONSUMPTION

ALTUN, M., ALAY, S., KARAKILIÇ, M.

**GAZI UNIVERSITY, ANKARA, TURKEY., KIRIKKALE UNIVERSITY, KIRIKKALE, TURKEY.*

Introduction & aim: Fans that are highly attached to their sports teams often purchase more licensed team merchandise (Wann &Branscombe, 1993; Fisher &Wakefield, 1998) and attend more games (Trail, Anderson &Fink, 2003) than fans with low involvement because of their desire to achieve a strong affiliation with the team. Basic personality traits such as extraversion, agreeability, and need for arousal positively affect the need for affiliation, and the need for affiliation positively influences the level of identification with the team (Donavan, Carlson &Zimmerman, 2005). Therefore, the aim of this study was to examine the effects of sport fan identification and fan personality types on purchasing licensed team merchandise.

Methodology: A total of 381 undergraduate students aged between 18 and 30, participated in the study. They were randomly selected, and those who were a football sport fan were included in the study. The Turkish version of Wann & Branscombe's (1993) Sport Spectator Identification Scale (Günay &Tiryaki, 2003) and the Turkish version of John, Donahue &Kentle's (1991) BFI (Evinç, 2004) were used to collect data. Product consumption of the fans was determined by asking them asking them the number of licensed products purchased from their teams' stores in the last one year. Independent sample t-test and regression analysis were used to analyze the data.

Results: revealed that there is a significant difference among gender groups on their team identification levels [t379= -5.895, p<.01]. Male fans' team identification (x=39.08) is higher than that of female fans (x=31.39). However, there is not a significant difference among gender groups with respect to their teams' licensed product consumption [t192= -1.289, p>.05]. The regression results showed that there is a significant relationship between the fans degree of team identification and their teams' licensed product consumption [R=.290, R2= .084, F(1-192)=17.591, p<.01]. Nevertheless, there is not a significant relationship between the personality traits of the fans and their teams' licensed product consumption [R=.163, R2= .027, F(5-188)=1.028, p>.05].

Conclusion: The results revealed that male fans are highly identified with their teams than female fans. The degree of fan identification affects fans' purchasing attitude that is, the higher the identification of fans with their teams, the higher the frequency of purchasing licensed team merchandise. This finding is consistent with the finding of Wann &Branscombe (1993), and Fisher &Wakefield (1998). Personality traits do not affect fans purchasing attitude. It could be said that personality trait is not a factor to predict the purchasing attitude of fans.

A SURVEY OF GOLF COURSE MANAGEMENT IN SCOTLAND

YOSHIHARA, S., KITA, T., YAMAMOTO, T., MOCHIZUKI, K., AOYAMA, H., AKITA, K., MIURA, K., MIURA, M., TAMURA, M.

ST.MARIANNA UNIVERSITY

Introduction: Golf is popular in many parts of the world as a sport of ladies and gentlemen. Golf has a large market from the viewpoint of sports business. We previously researched marketing and customer services performed by golf courses in Japan (Horie, et al., 2006) (Kita,et al., 2006). In the present study, we investigated marketing/management measures implemented or planned to attract new customers by golf courses in Scotland.

Methods: In this study, a survey was performed in 310 golf courses in Scotland. The survey was performed from September 1 to 31, 2006 by mailing questionnaires. Responses were obtained from 29 golf clubs with a recovery rate of 9.4%.

Results: "Revision of green fees" (55.2%),was the most common measure currently taken to increase profits at the golf courses surveyed. Subsequently, common measures included "renovation and construction of facilities"(27.6%),"cost reduction" (27.6%),"renovation and construction of course" (27.6%),"database of customers" (24.1%),"information services using information technologies" (24.1%),"enhancement of promotion" (20.7%),"customer development" (17.2%), "improvement of unprofitable operations" (17.2%),"securing of high-quality personnel" (13.8%) "enhancement of market surveys"(3.4%), and "enhancement of houses"(13.8%). Special customer service were provided at 6.9% of golf clubs, not provided at 65.5%, planned at 13.8%, and no specific comment was given by 13.8%. Detailed content of service were "easy payment plans" etc.

Discussion/Conclusion

In a similar survey with golf courses in Japan, the implementation rate of "cost reduction" was the highest, reaching about 80%, special customer service provided at 53.8%, which could have been considerably affected by the prolonged economic recession. In the future, we would like to obtain more detailed data based on factors such as the golf culture and economic conditions in each country.

THE OPINIONS OF AUDIENCES TO INCREASE THE APPEARENCE OF HANDBALL IN TURKISH PRINT MEDIA

CELIKSOY, S., CELIKSOY, M.A.

ANADOLU UNIVERSITY

THE OPINIONS OF AUDIENCES TO INCREASE THE APPEARENCE OF HANDBALL IN TURKISH PRINT MEDIA

Celiksoy, S., Celiksoy, M. A.

Anadolu University, School of Physical Education and Sports Eskişehir/TÜRKİYE

INTRODUCTION: It can be said that although handball is one of the sports that has scored several successes, it is neglected by audiences and print media. In spite of this discrepancy in Türkiye, there are some leagues, which are shown increased interest, such as ASOBAL Liga in Spain, Handball Bundesliga in Germany, Handboll Elit Serien in Sweden, TDC Liagen in Denmark. Furthermore, handball is being shown interest by print media in Korea, Egypt and Tunisia.

All sports including handball and media have dynamic relations to market sports as commercial entertainment in the world. Audiences are affected by sport events, they take a strong interest in factitious events they read rather than real life they live in. As a result, they forget their daily problems, teams and athletes' problems or successes become more important.

In this research we tried to find the answer of the following question; What are the opinions of audiences to increase the appearance of handball in Turkish print media?

METHODS: In this research a questionnaire was used. There were 15 items in Likert scale, 8 questions for demographic characteristics and personal information. It was applied to 386 audiences.

FINDINGS : More than half of the audiences are under the age of 20 (% 52.1), % 47.9' are male, %52.1are female, most of them are single (%78.4), more than half of them have 500TL income (% 52.5), most of the are students (% 68.1), % 69 of them do/play sports and % 65 of them have knowledge about handball. According to arithmetic average and standart deviation of 15 items,'5 the most important, 1 not important, the item of 'success in sport' is at the top with (4.66) arithmetic average and (0,613) standart deviation, the item of 'athletes' daily life'is at the bottom with (2.97) arithmetic average and (1,348)) standart deviation

RESULTS AND DISCUSSION: It can be defined that more than half of handball audiences in Türkiye are students, single, young and they have low income,

According to their opinions, the items such as success in sports, advertisement, handball in media, educational and magazine tv programs about handball, precautions and changes to make handball more exciting, sponsorship contracts for handball, media as a sponsor for handball, transferring popular handball players to Türkiye are most important.

SPORT SPONSORSHIP AS A FINANCIAL RESOURCE IN TURKEY

YORUC COTUK, M., BAKIR, M.

MARMARA UNIVERSITY

Introduction: Economic dimension of sponsorship is continiously growing in the world. In this context, sport sponsorship has reached a global volume of 80 billion dollars in 2004 (1, 2). The aim of this study was to evaluate the effects of sport sponsorship contracts on individual athletes and sport clubs in Turkey, besides the general and specific motives of corporate organizations for the establishment of a sport sponsorship relation.

Methods: A semi structured face to face interview technique was applied to five specialists of sport sponsorship in order to identify relevant items for the questionnaire which was used for the quantitative evaluation. That questionnaire was applied to the following groups:

1. Individual athletes with sport sponsorships (29 athletes)

2. Sport clubs with sport sponsorships (27 clubs)

Results: Although group related differences of sport sponsorship exist for individual athletes and sport clubs, both groups struggle with similar procedures and difficulties. The athletes were supported financially for participating in the national and international events, and related revenues. The clubs were supported financially by the sponsors for participating in the national and international events, health related expenses, name rights and related revenues. But the financial support both for individual athletes and sport clubs, remained inappropriate. There were substantial divergences in the concept and application of sport sponsorship between the corporate organizations (the sponsors) and both individual athletes and sponsored sport clubs.

Discussion: The inadequate perception of sport in Turkey hinders the increase of sport sponsorship support. In order to develop and determine the status of sport sponsorship of individual athletes and sport clubs in Turkey, redaction of variance in sport sponsorship procedures and increase of the effectiveness of sport sponsorship legal and administrative steps covering all sport activities should be taken.

THE DETERMINATION OF DEMOGRPHIC CHARACTERISTICS OF HANDBALL PLAYERS IN FIRST DIVISION

CELIKSOY, M., CELIKSOY, S.

ANADOLU UNIVERSITY

Introduction: The marketing of different sport branches need not only the success of the given sport, but also the number of spectators and the demographic characteristics of the participants. It can be said that the activities that are launched for finding sponsors are not enough in Turkey. The determination of demographic characteristics of Handball players in first division and to help bringing together the elite handball players with sponsors.

Method: A questionnaire has been prepared for gathering information on the demographic characteristics of the handball players (n=100, team n=7) in first division. The population of the current study is the total number of teams playing in the first division of Turkish Handball Federation during the session of 2007-2008.

Results: The analysis of the findings of the current study has shown that the players of Turkish Mans First handball division were 35,1 percent of them having the age range of 24-26, 81,6 percent of them were single, 77,3 percent of them were having undergraduate degrees, 65 percent of them had more than 2000 TL wages, 64,9 percent of them were living in a city centre, 85 percent of them were not having more than 2 sisters and/or brothers, their parents were having degrees higher than secondary schools and working as a governmental stuff and having middle class standards (38 percent of them having 1.500 TL or more income rates) in the Turkish standards. Besides, 44 percent of the players were team members of 1-3 years, 52,5 percent of them were chosen as handball players by their PE teachers. 25,8 percent of players choose reading books, 25.8 percent of them surfing in internet, 22,6 percent of them prefer listening music and 15,4 percent of them join activities like cinema/theater/concert etc. in their spare times.

Discussion: It can be concluded that the findings of the current study has shown that most of players of the Turkish Mans First handball division are young and single, having undergraduate degrees, reaching the level of middle class income rates in Turkey and coming from middle class families. It can be also said that most of them are city-dwellers and enjoy reading, listening music, dealing with computer and having high cultural level. The findings of the current study should be shared with Turkish Handball Federation for reaching to the potential sponsors.

SOCIAL INTEGRATION AND NATURE SPORTS: A RESEARCH ON UNIVERSITY STUDENTS IN TURKEY

YILMAZ, B., KARLI, Ü., YETIM, A.A.

NIGDE UNIVERSITY, NIGDE., TURKEY, 1. GAZI UNIVERSITY, ANKARA, TURKEY

Introduction:The purpose of this study was to explore the contribution of the nature sport activities on the social integration of the university students.

Methodology:The population of the research was composed of subjects who were university students and also members of the nature sports communities in the universities of Ankara. The sample of the research was consisted of 587 (male 341,female 246) university students. Social Integration in Sports Scale was used as the data collection instrument, which is composed of 7 sub-scales (personal development, 0.80; socialization, 0.82; physical benefit, 0.80; social integrity, 0.82; psychologic development, 0.71; moral development, 0.75; and emotional development, 0.55) and 32 items (Yılmaz, Karli, &Yetim, 2006). The data collection instrument was comprised of two main sections. In the first section, there were questions seeking demographic information (age, gender, residence place, involvement frequency to the nature sport activities) from the subjects, and the second section was composed of SISS items.

Statistical Analysis: To analyze the data, ANOVA was used to define social integration level differences of subjects according to their demographic characteristics such as; gender, residence place, meeting frequency with friends and involving frequency to the activities. To identify the difference causing group as the result of ANOVA, Tukey HSD Test was conducted. To display if any difference occurred in the social integration levels of subjects according to their gender t-test was conducted. In the statistical analysis of the data .05 significance level was taken into consideration.

Results: There was significant difference in subjects opinions about the effect of nature sports on individual development [F(3-583)=1,610;P>,05] and socialization [F(3-583)=2,844;P<,05] according to their participation level to the nature sports activities. Additionally, significant difference was identified in subjects' opinions about the effect of nature sports on individual development [F(2-584)=11,179;P<,05], socialization [F(2-584)=13,600;P<,05], psychological development [F(2-584)=3,892;P<,05] and moral development [F(2-584)=4,727;P<,05] according to their meeting frequency with their friends. There was significant difference in emotional development sub-scale of effect of nature sports on social integration according to the subjects residence place [F(2-584)=5,441;P<,05]. Also, significant difference was found in socialization [t(585)=-3,005;p<0,05] and physical development [t(585)=-2,977;p<0,05] aspect of nature sports according to the gender difference.

Conclusion: Finally, present research, which was conducted to analyze the effects of nature sports on the social integration of individuals, resulted that sports integrative role may show variations according to the participants personal characteristics.

INTERCONNECTIONS AND INTERDEPENDENCY OF NORWEGIAN SPORTS FEDERATIONS AND SPONSORS, AND CONSEQUENCES CONSIDERING DOPING

ØDERUD, T.A.
NORGES IDRETTSHØGSKOLE

Introduction: After the big doping case in the 2001 Ski World Championships in Lahti, where almost the entire finish ski team tested positive for doping, it was shortly after reported that the Finish Ski federation had lost a great deal of money through the loss of sponsors. In international cycling the same thing happened after the doping case in the Tour de France in 1998. Many sponsors and TV companies have withdrawn from the sport because of repeated doping cases. Based on experiences in the past, this thesis look at what could be the consequences of a similar episode in Norwegian sports. The main questions are: Is the doping question a part of the interconnection between Norwegian sport federations and sponsors? And: What could be the consequences for the interdependency of Norwegian sports federations and sponsors in the case of a positive doping case? This thesis drews on organizational theory (Mitchell, Agle & Wood, 1997) and sponsor theory (Cousens, Babiak & Bradish, 2006) to exam the questions.
Method: Ten in depth interviews with strategically selected people from two different Norwegian sports federation: The Norwegian ski federation and the Norwegian Snowboard association, their main sponsor DnB NOR, a sponsor of The Norwegian ski federation; Nemi Forsikring ASA, and a sponsor agent.
Results: Early findings indicate that the sponsors have the opportunity, based on the contracts with the sport, to withdraw if there are any positive doping cases. When it comes to the actually work relations, doping is almost not mentioned, and the sport and the sponsors do not talk so much about it. On the other hand, just because it's not talked so much about, doesn't mean it's not important to the sponsors. The sponsor will not be associated with doping, but can however evaluate the circumstances for the positive doping case before they decide to withdraw or not.
Discussion: Based on the nature of the interconnection and interdependency between sports and sponsors, this thesis try to explain why the consequences of a positive doping case is not a matter of just what the contract says about doping, but is an evaluation of different factors done by the sponsors before they decide whether to withdraw from the sport.

THE USE OF COMPUTER-AIDED-DESIGN (CAD) FOR THE CONSTRUCTION OF AN INERTIA RIGID MODEL OF THE SKI JUMPER

MARQUES-BRUNA, P., GRIMSHAW, P.
EDGE HILL UNIVERSITY

Introduction: Different types of isometry inertia models of the human body have been developed for the mathematical modelling of aerial movements (e.g., Yeadon, 1990). Recent advancements in rigid modelling include the use of anthropometric data adjusted for 3-dimensional (3D) simulation (Dumas et al., 2007) and of CAD in support of computational fluid dynamics projects (e.g., Meile et al., 2006). CAD may be used to model variations in flight posture and to obtain inertial parameters for the assessment of flight stability in ski jumping. Thus, this study aimed to evaluate the use of CAD for the construction of an inertia rigid model for applications in ski jumping.
Methods: A 14-segment 3D rigid model of the ski jumper was designed using Delcam PowerSHAPE-e 8080 CAD software, adjusted anthropometric data (Dumas et al., 2007) and postural ski-jumping data (e.g., Meile et al., 2006). Variations in flight posture included ski opening angle (SOA) at 20°, 25° and 30° and forward leaning angle (FLA) sampled from 0° to 40°, at 10° intervals. The position of the centre of gravity (CG) and the principal longitudinal moment of inertia (Iy) were computed for each posture (Parallel-axes theorem; Yeadon, 1990). Inertial properties of the helmet, boots and skis were included using equations for symmetric objects of uniform composition (Griffiths, 2006).
Results: The mean ± SD position of the CG for all flight postures was 54.9 ± 0.2% of athlete's height. The mean ± SD Iy was 14.7 ± 0.3 kg • m2, where Iy decreased slightly with SOA but increased prominently with FLA.
Discussion/Conclusion
Iy increased noticeably with FLA; thus, FLA may be considered an important damping derivative in ski jumping that helps prevent departures from trimmed attitude. However, large FLA lowers the static stability. Drawing upon past research (Yeadon, 1990; Meile et al., 2006), CAD permitted modelling variations in flight posture and the computation of inertial parameters for the assessment of flight stability in ski jumping.

MECHANICAL EFFICIENCY AND SKIING SPEED DURING ROLLER SKIING WITH DIAGONAL STRIDE TECHNIQUES

NAKAI, A., ITO, A.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

The purpose of this study was to clarify how mechanical efficiency during submaximal level roller skiing with diagonal techniques (ME) changes with speed. ME was calculated with the total work rate which contained the work for body segment motions and for external loads, and also the energy expenditure rate measured under experimental conditions. Eight male intercollegiate cross-country skiers were roller skied with a diagonal stride at given speeds on an all-weather level track to videotape motions and measure oxygen uptake. The work rate which was supposed all mechanical energies could be transferred within and between all body segments and was summed increase in the whole body energy levels, and the work rate for overcoming frictional loads on roller skis were calculated. Then, both work rates normalized for body mass were summed. This total work rate was divided by the energy expenditure rate which was subtracted energy cost in a resting state, and thus ME was calculated. The results could be summarized as follows. ME increased remarkably with speed up to 3.6 m/s at which ME indicated the maximal value of 0.357, and subsequently shifted to a moderate decrease. This variation of ME could be attributed to reutilization of elastic energy stored in actively stretched muscle-tendon complexes and variation of recruitment patterns of muscle fibers with roller skiing speed. At low speed, less elastic energy could be restored and reused due to small force application and long coupling time in activated muscles, and therefore ME was lower. ME could have a significant increase at middle speed since slow-twitch (ST) fibers, which are efficient in low-intensity exercises, were recruited adequately, and stored elastic energies were reutilized efficiently during stretch-shortening cycles and hence energy expenditure was reduced. At more than middle speed, ST fibers, which deteriorated efficiency in high-intensity exercises, were recruited sequentially, and in addition recruitment of fast-twitch fibers, which were originally more inefficient than ST fibers, was started. These might cause augmentation of energy expenditure and modest degradation of ME consequently. Furthermore, it was suggested that ME during races could be almost as high as its maximal value.

BIOMECHANICAL FACTORS OF BIATHLON SHOOTING IN YOUTH, JUNIOR AND ELITE ATHLETES

SATTLECKER, G., MÜLLER, E., LINDINGER, S.

UNIVERSITY OF SALZBURG

In Biathlon many factors can have influence on the shooting results. Nitzsche (1998) consid-ered shooting position, targeting, breathing technique and triggering as main performance variables. Regarding stance stability and triggering Sattlecker (2007) stated that these two variables do not require a maximum or minimum, an individual optimum seems to be neces-sary. According to Nitzsche (1998) a pre shot triggering of at least 70 to 80 percent should be achieved. Comparisons between youth and elite athletes showed significant differences be-tween these two groups concerning shooting results, stance stability and triggering (Sattlecker 2009).

The aim of this study was on the one hand to compare 3 different age groups (youth, junior and elite biathletes). On the other hand it was important to measure the influence of stance stability-variables and triggering on the shooting results. Therefore 8 youth (15  1 yr), 5 jun-ior (18  1 yr) and 7 World Cup athletes (28  5 yr) were tested in May 2008. Each biathlete had to shoot 8 series of 5 shots in the standing and 4 series in the prone position. All shots were made without physical load. The measure station consisted of 1) Force plate (FiTRO Sway Check, SVK) for stance stability, 2) Oil force transducer at the trigger (Spezialmess-technik Ilmenau, GER), 3) Computer controlled display for the shooting results ("SA 921" - Sius Ascor, GER). The data were processed by iSportmanager-Biathlon (Ike-Software, AUT). As variables the mean pre-shot trigger force (TF) over one second before firing [in % of the maximum force], the deviation of the standing position [mm] in x-(cross shooting) direction (Xdev) and y-direction (in shooting course) (Ydev), the path length [mm2] (PL) on the force plate and the shooting results (1-10) (Score) were measured. For the prone shooting only TF and the scores were quantified.

For the standing shooting the results showed significant differences between youth and elite and between youth and junior athletes for the stance stability parameters (PL, Xdev, Ydev) but not for the triggering (TF). In prone shooting TF was significantly different between youth biathletes and the two other groups. Regarding the calculated relationships the results demon-strated high significant correlations between all stance stability parameters (PL, Xdev, Ydev) and the shooting scores, although the coefficients were low (-0,275; -0,170; -0,196; $p < 0,001$). For TF no significant correlation with the shooting results could be found. The results also showed that in most cases the correlations for the younger athletes are higher than for the World Cup biathletes.

The significant differences between the groups showed that stance stability and triggering seem to be relevant. Especially for beginners and young athletes the analysed variables look like being important for good shooting scores. It can be assumed that the correlations are low because biathlon shooting is a complex task with many other influencing parameters.

THE GROWTH AND DEVELOPMENT OF LOWER LIMB MUSCLE SIZE AND ANAEROBIC POWER GENERATION CAPACITY IN MALE SPRINT AND LONG-DISTANCE SPEED SKATERS.

KUMAGAWA, D., TANAKA, S., TAKAHASHI, Y., TSUNODA, N.

KOKUSHIKAN UNIVERSITY

Introduction: It was not cleared that the differences of the muscle structure and function due to growth and development in sprint and long-distance speed skaters. Therefore, in this study, the effects of growth and development on muscle size and maximal anaerobic power generation capacity in sprint (SG) and long-distance speed skaters (LG) aged 13-26 years were investigate.

Methods : The subjects were divided into 5 groups according to chronological age every 2 years in both SG and LG, respectively. The skater at aged 20 or over assumed it adult group (AG). All subjects had belonged to speed skating clubs and they performed training of the each type of speed skating all through the year. Body compositional parameters for body height, body mass, fat mass and fat-free mass (FFM) of the whole body were measured using the body impedance analysis method. The anterior (MTA) and posterior (MTP) thicknesses of the thigh muscles were measured using the B-mode ultrasonic method. Maximal anaerobic power (MAP) was determined using a bicycle ergometer.

Results: FFM, MTA, MTP and MAP increased with chronological age in both SG and LG. The FFM were significant higher in SG than LG in 13-16yr groups. In addition, the MAP was significant higher in SG than LG in 13-18yr groups. However, differences in FFM and MAP were not found among the AG. The MTA in SG were larger than those of in all groups of LG. The MTP in SG and LG were almost the same values in all groups. The ratio of MTA to MTP in SG showed significant higher than that of LG in AD.

Discussion: From these results, it was indicated that the fat free mass and maximal anaerobic power generation capacity in sprinters developed than long-distance speed skaters during pubescent period. In case of sprinters, it was considered that the knee extensor muscles developed than knee flexor muscles.

COMPARATIVE TECHNIQUE DIAGNOSIS OF THE CONTACT PHASE AND PUSH OFF PERFORMANCE IN CROSSCOUNTRY ROLLER <XCR> SKIING

VEITH, M., SCHWIRTZ, A.

TECHNISCHE UNIVERSITÄT MÜNCHEN

INTRODUCTION: Analysis of XC skating techniques deals with kinematic and kinetic aspects of upper and lower body motions and with resulting forces (Schwirtz, A., 1994). Studies concerning ground reaction forces showed different components of the total impulse (Lindinger S., 2006) but didn't analyze them individually. In this study we are interested in how the total impulse gets generated and if there are different solutions regarding the economy of a contact and push off phase.

METOHDS: 4 trained XC skiers performed 3 trails on roller skis in the V1, V2, V2 alternate and V skating technique. Plantar pressure was measured over an interval of 30s with F-Scan® Mobile insole sensors and analyzed with the Fast Scan Mobil Research 6.31 software package. The sampling rate was 30Hz. The pressure data was normalized and converted to force by means of body weight. For each trail one average contact phase was calculated and the average of that 3 contact phases constitute one representative contact phase. For distinguished analysis both feet were divided into 4 areas: 1st total, 2nd front-interior (FI), 3rd front-exterior (FE), 4th back (BA). Point of view was impulse of each area per body weight and the shift of load from back to forefoot.

RESULTS: The range of the total impulse of V2 was within 9,6-6,8N/kg for the right and 9,6-7,2N/kg for the left foot. Individually there were no conspicuous differences in the intensity between the left and the right foot. The percentage composition of the total impulse of the left foot was: skier1 36% FI, 15% FE, 49% BA. Skier2: 30% FI, 17% FE, 53% BA. Skier3: 44% FI, 8% FE, 47% BA. Skier4: 42% FI, 19% FE and 39% BA. Data of the right foot showed no striking differences. Regarding the shift of load from back to front skier1 and 2 shifted at about 50% of the contact phase whereas the other skiers already shifted at about 25%.

DISCUSSION: Generating the total impulses the athletes showed variable distributions of the 3 sub impulses FI, FE and BA. Skier 3 and 4 generated almost the same resulting impulse as skier1 but already shifted load from back to forefoot at 25% of time while skier1 finally shifted at 48%. Skier3 shifted the load onto his forefoot at 42% of time but 52% of the resulting impulse was generated from the back of his foot. In comparison to skier1, skier 3 and 4 had longer stance on the forefoot, skier3 longer stance on the back foot. They had longer contraction times of the involved muscles and a less explosive rate in the final push off. This could imply less O2 supply and worse economy. Those aspects could play a role in a differentiated diagnosis of the contact phase in XC skiing. In this running study the other skating techniques will be analyzed as well.

EFFECTS OF FATIGUE ON KINETIC PARAMETERS DURING A SIMULATED CROSS-COUNTRY SKI RACE. PRELIMINARY RESULTS

PELLEGRINI, B., BORTOLAN, L., FABRE, N., SCHENA, F.

UNIVERSITÀ DEGLI STUDI DI VERONA

Introduction: Fatigue is defined as a decrease in performance or in work capacity or as the inability to maintain a level of strength. Very few studies have analyzed the effect of fatigue on the technique in cross-country skiing in an ecological setting (on-field). The purpose of the study was to examine the changes induced by fatigue on kinematic parameters and force expression during a race simulation using diagonal stride technique.

Methods: Eight cross-country skiers were asked to complete a 12-km simulated race, consisting of 8 laps of 1.5 km each using classical style technique. The subjects were timed over each lap and passage along a straight and constant uphill tract (length: 130m, slope: 12%) that was covered using diagonal stride. The athletes were filmed over a field of 8m at the end of the uphill tract by means of 3D SIMI motion system. Length and duration of the cycle (CL; CT), of the gliding phase (GL; GT) and the duration of the propulsive phase (PT) were calculated. The plantar and the pole forces were recorded over the whole simulation using a Novel Pedar System and load cells inserted under the handgrips. Mean force, peak force and duration of the propulsive phase were considered for both skis and poles during uphill tract. Blood lactate concentration was measured at each lap. Mean parameter of the first lap (L1) and last lap (LL) were compared.

Results: Preliminary analysis on the first two skiers (S1 and S2) indicated a reduction of the speed (S1:2.89m/s for L1, 2.68m/s for LL; S2: 2.98m/s for L1, 2.59m/s for LL) on the uphill tract. The mean value for lactate concentration was 7.5mmol/l and no values below 6mmol/l were found. Temporal variables showed a slight decrement of the GT (S1:0.29s for L1, 0.26s for LL; S2:0.25s for L1, 0.21s for LL) associated to a reduction of the CL (S1:3.35m for L1, 3.32m for LL; S2:3.05m for L1, 2.66m for LL) and GL (S1:0.49m for L1, 0.46m for LL; S2:0.43m for L1, 0.31m for LL). The plantar peak force decreased in both athletes (S1:1118N for L1, 1043N for LL; S2:1190N for L1, 1136N for LL) while the mean force decreased only in one athlete (S1:416N for L1, 363N for LL; S2: 521N for L1, 525N for LL). The PT increased according to both kinematic and plantar force data (S1:0.35s for L1, 0.37s for LL; S2: 0.31s for L1, 0.34s for LL). The poling data did not show substantial differences between first and last lap.

Discussion: The high lactate concentration confirmed that the exercise was performed at high intensity, and the decrease of speed between the first and last lap indicated the occurrence of fatigue. The most evident effect on the spatio-temporal parameters is the de-

crease of both the duration and the distance travelled during the gliding phase. Moreover, the reduction of the peak force and the increment of the propulsion time across laps seems to indicate that fatigue mainly reduce the dynamical characteristic of the legs propulsion.

SKI-SNOW INTERACTION MECHANICS DURING THE TRANSITION FROM SKIDDING TO CARVING IN COMPETITIVE ALPINE SKIING

HAUGEN, P., REID, R.C., GILGIEN, M., KIPP, R.C., SMITH, G.

NORWEGIAN SCHOOL OF SPORTS SCIENCE

Skiers manipulate the orientation, edging and pressure of their skis on the snow surface to control their path of motion. Understanding the nature of the ski-snow interaction can thus be important for coaches and skiers for technique and performance optimization. Using a model based on metal cutting theory, Lieu & Mote [1] predicted that the carving process is initiated at the aft-most portions of the ski during the transition from skidding to carving, and that carving is limited to the ski after-body. These are concepts which, if true, have important implications for skiing technique and equipment development yet are poorly understood amongst practitioners. The purpose of this study was to examine how well the Lieu-Mote model predictions correspond to empirical data from a kinematic study of skier technique.

METHODS: Six male Norwegian national team members completed a slalom race simulation on 2 rhythmical courses set with 10 and 13 m gate separations. Ski 3D position data were reconstructed using 4 panning video cameras for 2 complete turns per athlete per course. The ski position data were then fit with a 15 segment ski model of 14 m sidecut radius. The whole ski attack angle was calculated as the angle between the ski longitudinal axis and the ski center point velocity vector in the plane of the local snow surface [1]. Similarly, the local attack angle at each ski segment was calculated to describe the extent of carving at each point along the ski's length. Local ski attack angle data were averaged according to whole ski attack angle across all trials and subjects for the turn phase of the turn cycle.

RESULTS AND DISCUSSION: Some variability in local ski segment attack angle patterns was apparent, likely due to variation in the mechanical and geometrical properties of the skis used by the athletes. In general however, local attack angles were high along the entire ski when whole ski attack angles were greater than about 12°, indicating that skidding processes dominated. Below this level, local attack angles in the aft-most ski segments diminished while those of the fore-body segments remained elevated. Local attack angles of the aft-most segments reached 2-5° as whole ski attack angles approached 8°, indicating the initiation of the transition to carving in good accordance with Lieu and Mote's [1] predictions. Further decreases in the whole ski attack angle were associated with increasing numbers of tail segments carving along with the reduction of fore-body segment attack angles. The ski reached an advanced carving stage at whole ski attack angles of approximately 2.5°, although fore-body segment attack angles remained slightly elevated indicating that this part of the ski was still machining new snow.

CONCLUSION

The ski motion characteristics observed in this study are in good accordance with Lieu and Mote ski and snow interaction model.

FORE/AFT MOVEMENT IS ADAPTED TO GATE SEPERATION BY ELITE ALPINE RACERS IN SLALOM

KIPP, R.W., REID, R.C., GILGIEN, M., HAUGEN, P., SMITH, G.

NORWEGIAN SCHOOL OF SPORT SCIENCES (OSLO, NORWAY)

Fore/aft position and movement have been shown to be related to performance in slalom [1,2]. These studies were carried out on a relatively tight slalom course using gates set with 10 m separation. This follow-up study from the same day tested similar relationships for slalom turns through a more open course with 13 m distances between gates.

Methods. The performances of 6 members of the Norwegian men's Europa Cup team were analyzed through 2 complete turns during a 13 m slalom race simulation. Skier 3-D positions were determined from 4 panning cameras and calibration control points distributed near the course [3]. Utilizing the method of Schiefermüller [4], a local coordinate system (LCS) originating at the outside ankle joint center was defined at each point in time.

Motion of the body center of mass in the LCS fore/aft direction was divided into fore and aft phases of positioning relative to the outside ankle joint and time normalized to the turn cycle. Fore and aft position data were separately integrated over time in the positive and negative portions of the turn cycle and were then divided by the percent of turn cycle which they represented. Finally, the forward values were divided by the aft values to create a fore/aft ratio where a value of 1 would indicate a symmetrical distribution of fore/aft positioning about the ankle joint center. Ratios greater than or less than 1 thus indicated positioning which was biased either forward or backward, respectively. These ratios were then correlated with performance time controlling for each skier's entrance velocity.

Results. The mean fore/aft ratio for the 13 m course was 1.27 ± 0.54. The partial correlation coefficient between the fore/aft ratio and performance time was 0.735 ($p = 0.03$). This follow-up study found that when the turns changed from 10 to 13 m, the fore/aft ratio decreased from 2.44 ± 1.41 to 1.27 ± 0.54, indicating that skiers, on average, were further back and more fore/aft symmetric on the 13 m course. A two tailed t-test, assuming unequal variances, between the previous 10 m fore/aft ratios [1] and the current 13 m fore/aft ratios yielded a $p = .10$.

Discussion. Fore/aft positioning of a slalom skier has been shown to be significantly related to performance. The correlation between fore/aft ratio and performance time was significant and positive for both 10 and 13 m courses ($r = 0.980$ and 0.735 respectively). Fore/aft positioning graphs were observed to be differently shaped for the two courses with more constant, closer to centered positioning for the 13 m course. This may in part be due to the increased time available between turns (about 12%) allowing different strategies.

CADENCE ADAPTATIONS OF DOUBLE POLING TECHNIQUE IN ELITE CROSS-COUNTRY SKIERS

LINDINGER, S.J., HOLMBERG, H.C.

UNIVERSITY OF SALZBURG

During the last decade, double poling (DP) became a main classical technique in cross-country (XC) ski racing. A recent study analyzed speed influence on biomechanics of DP and found increases in poling frequency, cycle length, peak pole force, flexion and extension ranges of motion and angular velocities in arm and leg joints and decreases in poling time and time to peak pole force (Lindinger et al, 2009). Cadence and its influence on exercise is well investigated in different cyclical activities like running, race walking, swimming, etc. (Marais et al. 2003) but rarely anaylzed in XC skiing (Millet et al. 1998). The purpose of a bigger project was to answer the question "Does an optimal cadence exist and which factors determine the choice of cadence?". The aim of the current biomechanical study was to analyze the influence of different cadences on three submaximal velocities during DP.

10 elite XC skiers roller skied using DP at three given cadences (40, 60 and 80 pole thrusts per min [t •min-1]) performed at three submaximal treadmill velocities (12, 18, 24 km•h-1). Joint angles (Noraxon, Germany), EMG activity of triceps brachii and axial pole forces (strain gauge system) were measured by Noraxon-System (Germany). Repeated ANOVA were calculated to analyze changes in all variables across cadences at all speeds (statistical level $P<0.05$).

Poling time decreased with higher cadence ($P<0.05$) and reached critically short values of ~0.2 s at 80 t •min-1 at 24 km•h-1 compared to ~0.3 s at 40 t •min-1. Relative poling and recovery time (% cycle time) increased and decreased with higher cadences (all $P<0.05$) showing minima and maxima of ~20 and ~80% cycle time at the lowest cadence of 40 t •min-1. Peak pole force and impulse of pole force decreased with increasing cadence leading to smaller power outputs per cycle at high DP cadences (all $P<0.05$). Heel lift, elbow, hip and knee joint flexion and extension ranges of motion and angular velocities decreased with higher cadences at all speeds (all $P<0.05$). Triceps pre-activation and MPF increased with higher cadences whereas average EMG during flexion and extension phase decreased (all $P<0.05$).

Today's top skiers adapt to higher cadence by decreasing absolute and increasing relative poling times, decreasing forces and impulses of forces, upper and lower body joint motions and changing EMG activity. In contrast cycling the change of joint kinematics is unique and might affect work economy during DP at different cadences. Anthopometry, technique and muscle quality might play a crucial role concerning the question "Which is the optimal cadence during DP in XC skiing?". Further investigations will be necessary to answer these important questions.

THE EFFECTS OF SPRINT, RESISTANCE AND PLYOMETRICS TRAINING ON SPRINT ACCELERATION KINEMATICS AND MUSCULAR FUNCTION

LOCKIE, R., MURPHY, A.

UNIVERSITY OF NEWCASTLE

A range of interventions are used to enhance sprint acceleration. However, the means by which these training modalities improve sprinting remains unknown. The study aim was to assess 4 common protocols (free sprint [FST], weights [WT], plyometrics [PT], resisted sprint [RST]) for changes in acceleration kinematics and maximum muscular power and strength.

35 men (18-39 yrs) were divided into 4 groups (FST=9, WT=8, PT=9, RST=9) matched for 10m sprint performance. Kinematic analysis included velocity, step length and frequency, and contact and flight time during a 10m maximal sprint. Vertical (countermovement jump: CMJ), horizontal (5-bound test: 5BT), and reactive (drop jump: RSI) power and strength (3-repetition maximum squat: 3RM) were also assessed. Training involved 2 1-hr sessions a week for 6 weeks. The sprint programs commenced with a volume of 195m rising weekly by 20-30m. The WT program progressed from 75% to 90% 1RM by Week 6. The PT program began with 100 ground contacts, and increased by 12-20 contacts per week. Significant ($p<.05$) within-group changes were verified by paired samples t-tests.

Following training, each group increased 0-5 and 0-10m velocity by ~9-10%. The WT and PT groups increased 5-10m velocity by ~10%. Each group increased step length in all intervals. The FST group decreased step frequency in all intervals and 0-5m flight time, and increased 0-5 and 0-10m contact time. The FST group improved 5BT. The FST, PT and RST groups increased RSI. All groups increased the 3RM squat; the WT group had the highest percentage gain.

The enhanced step length experienced by all groups signified specific horizontal power gains, but only the FST group increased 5BT. This change for the FST group contributed to the increased contact time, which allowed for greater horizontal force expression leading to lengthened steps. Reduced flight time balanced the contact time change. All protocols that increased RSI involved ballistic actions indicative of reactive power. For the PT and RST groups, this adaptation permitted contact time maintenance following training. The WT group's improved strength increased the ability to use concentric force to generate speed, primarily through step length increases. This was vital as this group did not have significant increases in power, which may limit adaptations for extended sprints (>10m). This improved strength may also have permitted contact time maintenance following training.

This study has revealed critical information about the outcomes of specific protocols on sprint acceleration. With correct administration, all protocols from the current study can improve acceleration, primarily through step length development. The underlying power and strength adaptations contributing to speed improvement are protocol-specific. Step length may be the major limiting factor for sprint performance in field sport athletes. It is recommended that specific horizontal power be developed to enhance field sport acceleration.

EFFECT OF AGEING ON EQUILIBRIUM: INCREASE IN PERCENTAGE OF TORQUE EXERTED AT THE ANKLE JOINT

BILLOT, M.

INSERM U887

Billot Maxime, Simoneau Emilie, Van Hoecke Jacques, Martin Alain

Laboratoire INSERM U887 Motricité-Plasticité, Faculté des Sciences du Sport, Université de Bourgogne, F-21078 Dijon, France

maxime.billot@u-bourgogne.fr

Background: Whatever the age, ankle joint muscles play an important role to maintain upright standing (Amiridis et al., 2003). More specifically, differences of stability have previously been observed with aging, notably by assessment of centre of pressure (CoP) displacement. Moreover, aging induced a decline in maximal voluntary contraction (MVC) at the ankle joint in both plantar- (PF) and dorsiflexion (DF) (Simoneau et al., 2009). The aim of this study is to quantify the necessary torque at the ankle joint to maintain different postural tasks, and to observe this torque from the MVC capacity in young and older adults.

Methods: Eight young adults (Y) (22.8 ± 2.4 years; 1.77 ± 0.04 m; 67.1 ± 8.4 kg) were compared with seven older individuals (O) (80.0 ± 4.2 years; 1.66 ± 0.06 m; 75.0 ± 9.6 kg) during three postural tasks (Normal Quiet Stance (NQS), Romberg (ROM) and One Leg Balance (OLB). CoP displacement was measured via a force plateform during 10s for each condition. MVC was measured in isometric DF and PF via a forceplate. The electromyographic (EMG) activity of triceps surae and tibialis anterior muscles was recorded simultaneously. To estimate torque during postural tasks we reported EMG during upright standing into the relationship between EMG activity and torque obtain from sub-maximal contractions (5, 10, 20 and 30 % of the MVC in the DF and PF).

Results: Aging induces an increase of the CoP displacement in the two most complex postural tasks (i.e. ROM ~ + 38 %, $p < 0.05$ and OLB ~ + 86 %, $p < 0.001$). A significant decrease in the DF (~ - 36 %) and PF (~ - 32 %) agonist torques was also observed with aging ($p < 0.01$). During every postural task, the torque exerted in DF and PF was not significantly different between Y and O ($p > 0.05$). However, we observed that the torque in % MVC is greater for older than young adults in ROM (26.6 ± 4.6 % vs. 15.0 ± 5.1 % respectively, $p < 0.01$) and OLB (41.9 ± 7.8 % vs. 23.7 ± 6.1 % respectively, $p < 0.001$), but not in NQS (10.7 ± 4.4 % vs. 5.6 ± 1.2 % respectively, $p > 0.05$).

Discussion: Our study report that despite the increment of the CoP displacement with aging, we observed that torque needed to maintain a postural task is not significantly different between Y and O. Nevertheless, older adults used a greater percentage of MVC during the most complex postural task. Finally, this finding suggests that fatigue could be induce when older adults are in a difficult posture and thus provoke a significant increase in fall risks.

NEUROMUSCULAR STRATEGIES IN THE CASE OF RAPID AND HIGH IMPACT LOADS: IMPACT VERSUS TASK DEPENDENCY?

GALINDO, A., ISHIKAWA, M., CHAVET, P., BARTHÈLEMY, J., NICOL, C., AVELA, J., KOMI, P.V..

FACULTY OF SPORT SCIENCE

Introduction: In landing, the neural strategy is adjusted as a function of the required muscle-tendon stiffness at impact (Santello, 2005). This has been thought to result from regulation of leg extensor muscle preactivation. For the post-impact phase, evidence was obtained that both the reflex and central regulations are involved. Our recent study (Galindo et al. 2009) investigated the influence of different pre-set force levels on the post-impact muscle activation. The main finding was the similarity across all conditions of the post-impact electromyographic (EMG) activity, including the short latency reflex (SLR) response. This was mostly attributed to the similar EMG levels reached at impact despite the instruction to maintain a given force level. This might suggest a pre- to post-impact continuum of neural adjustments to prevent overloading of the tendomuscular system. The present study investigates further the impact vs. task dependency of the observed protective neural strategy.

Methods: The testing protocol was performed on a sledge apparatus with a single lower limb and in a seated position. To evaluate the impact influence, landings were performed either from a maximal (H100) or from a supra-maximal (H200) dropping height, with the instruction to resist the impact. To examine the task influence, subjects were released from the H100 dropping height, with the instruction to either land or rebound. A lower limb guiding device fixed to the front of the sledge seat allowed the subjects to sustain a given pre-set force level up to impact. The force level was set at 20, 35 and 50% of maximal isometric plantarflexion force. EMG activity was recorded from 8 major lower limb muscles.

Results: As expected H200 led to higher impact peak force (826 ± 41 kN) than H100 (684 ± 49 kN) ($P<0.05$), but the EMG patterns did not differ among the pre-set force conditions. The early (0-100ms) post-impact EMG pattern of the triceps surae was particularly stable, including its SLR response. The landing vs. rebound comparison emphasized the stability of the early post-impact EMG pattern, but revealed a decrease prior to impact and increase during the late post-impact phase.

Discussion: The overall EMG stability during the early post-impact phase demonstrates the intervention of a protective neural strategy during this specific time period. As indicated by the compensatory neural adjustments observed in the rebound task during the pre-impact and late post-impact phases, this neural strategy is not task dependent. The absence of neural adjustment to the impact peak force is in contrast with the literature (Santello, 2005). The EMG stability is attributed to the extremely rapid timing of the impact force peak: 5 ms (present study) vs. 25 ms (Kamibayashi & Muro 2006).

THE ASSESSMENT OF GOLF SHOE-SOLE INTERFACE TRACTION ON NATURAL GRASS

WORSFOLD, P.R., SMITH, N.A., DYSON, R.

1. UNIVERSITY OF CHESTER, UNIVERSITY OF CHICHESTER

Introduction: Damage to golf course turf by traditional metal spiked golf shoes has resulted in the development of new shoe sole designs based upon the inclusion of plastic alternative spikes. Evaluation of such shoes has been reported in terms of mechanical force generation at the sole-artificial grass (astroturf) interface but not at the natural grass interface (Williams and Sih, 1998). The aim of the present study was to compare the traction (torques and forces) generated between different shoe-sole interface designs on natural grass surface using a mechanical traction-testing rig and during dynamic golf shots.

Method: Three golf shoe designs were assessed (A,B,C) All shoe types were identical except the number and type of sole spikes on each shoe-sole interface. During the dynamic testing eighteen golfers (HC <15) completed ten shots using a driver in each shoe condition while standing with each foot on a grass turf covered force platform. Mechanical testing was conducted on the same shoes used in the dynamic tests. Shoes were placed with the sole interface flat on the ground (whole-foot) and with only the forefoot of the shoe on the ground representing the shoe positions during different stages of a golf swing. For both testing modalities, the natural turf was attached to the top of Kistler force platforms (1000Hz) (Janaway and Dyson, 2000). The peak, range and coefficient of friction was assessed within linear (Fz, Fy) and rotational (Tz) variables for both the dynamic and mechanical tests. One-way analysis of variance with repeated measures was used to assess any differences in the forces generated between the shoe conditions in each of the testing protocols. The between shoe differences were then compared between the two traction tests.

Results: Mechanical traction testing results identified shoe A to produce significantly less ($P<.05$) traction within all linear and rotational variables when compared to all other shoe conditions. Shoe B produced significantly greater ($P<.05$) traction within all linear and rotational variables when compared to shoes A and C. Dynamic analysis during the golf swing identified no significant ($P<.05$) differences between the shoe-sole interface designs within all linear and rotational variables with all shoe conditions performing comparably to each other.

Discussion: The contradictory results suggest it is not appropriate to test shoe-sole interfaces using mechanical testing devices and relate them to a dynamic sporting movement. Only through testing actual dynamic sports specific movements can an accurate understanding of the performance characteristics and interactions of sports shoes and the ground be gained.

GROWTH AND DEVELOPMENT OF LOWER LIMB MUSCLE AND BALL KICKING PERFORMANCE IN MALE SOCCER PLAYERS

TESHIMA, T., TSUNODA, N.

KOKUSHIKAN UNVERSITY

Introduction: The purpose of this study was to investigate the effect of lower limb muscle size on ball kicking performance in Japanese male soccer players.

Methods: One hundred thirty-eight Japanese male soccer players aged from 12 to 22 years old were participated as subject. The subjects were classified three groups (JG: Junior high school group, n=43. HG: High school group, n=18. UG: University group, n=77). Muscle thickness of TA (thigh anterior including rectus femoris : RF and vastus intermedius : VI) and TP (thigh posterior) were measured by Ultrasonography method (SSD-900, Aloka). Three cross-sectional planes were imaged at 30%, 50% and 70% of femur length from trochanter major to lateral condyle of femur, starting at the trochanter major. In all subjects, the maximal kicked ball velocity (BV) was measured by Rader gun (Mizuno, Japan.) in distance of 5m with the three trials. The ratio of RF and VI (RF/VI ratio) was calculated in all the subjects.

Results: Muscle thickness of TA was showed significantly wider in 30% than 50% and 70% in each group. There were significant differences between 30%, 50% and 70% in muscle thickness values of VI and RF in each group. RF/VI ratio was obtained significantly lower value in 70% than 30% and 50% in each group. Muscle thickness of TA was showed significantly higher in UG than JG and HG in measured all site. Muscle thickness of RF at 50% was significantly differed in each age group. Whereas, there were not significant differences between JG and HG in 70% RF muscle thickness and HG and UG in 30% RF muscle thickness. RF/VI ratio was not significant difference in 70%, however significantly higher ratios in JG were observed in 30 and 50%. BV was showed higher value in UG than the other groups. In JG, TA muscle thickness was significantly correlated to the BV in measured all site. And also, muscle thickness of RF was closely related to the BV in JG.

Discussion: Muscle thickness of TA at 30% was showed higher value than the other sites in all groups. RF muscle thickness at 30% was increased from JG to HG, In case of 70% site RF muscle thickness was increased from HG to UG. It means that the growth of muscle in RF may be differed by site in lower limb. AT muscle thickness was closely related to the ball kicking performance in JG. And also, Muscle thickness of RF correlated to the kicked ball velocity in JG, whereas muscle thickness of VI was not related to the kicked ball velocity in all the age groups. From these results, it was suggested that level of muscle growth might be affected on ball kicking performances in adolescent soccer players.

CHARACTERISTICS OF MUSCLE ACTIVITY IN THE UPPER LIMB DURING BASEBALL BATTING

SAKASHITA, I.

NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA

Introduction: Recordings of surface electromyography (EMG) with kinematic data are useful to evaluate muscle activities during baseball batting. We examined differences in the reproducibility of muscle activity parameters and swing time in the impact phase between baseball players and non-baseball players.

Method: Subjects comprised 21 male students (14 baseball players, 7 non-baseball players) performing a practice swing and 10 baseball batting trials using a baseball bat (length, 83 cm; weight, 900 g) so as to cross two photoelectronic sensors set 15 cm apart on the home plate. EMG in upper limb muscles and elbow joint angles was simultaneously recorded during bat swing trials. Electromyographic signals from the left (leading) and right (trailing) triceps brachii (TB), biceps brachii (BB), pectoralis major (PM), trapezius (TRA), and latissimus dorsi (LD) muscles were recorded with the left elbow joint angle. Myoelectric signals were recorded from each muscle using surface electrodes. Before each experiment, isometric force at MVC of each muscle was measured, and the highest of three maximal efforts was used as MVC force. Time differences between signals from photoelectronic sensors were determined as bat swing time. EMG activities during the bat swing phase were analyzed to evaluate the reproducibility of muscle activity patterns.

Result: The times for practice swing (S) and batting (B) were 6.8 ms and 6.1 ms in baseball players, and 8.8 ms and 7.1 ms in non-baseball players, respectively. Swing speeds for S and B were 21.5 m/s and 23.4 m/s in baseball players and 17.2 m/s and 20.3 m/s in non-baseball players, respectively. Coefficients of variation were also 6.0 and 4.7 in baseball players and 5.6 and 4.7 in non-baseball players, respectively. EMG activities in the PM, TB, BB, TRA were higher than in RA or LD in baseball players. We observed variable patterns of muscle activities at the impact phase in both batting and practice swing. Higher coefficients of variation for mean EMG (mEMG) in the TB showed in the leading arm compared to the trailing arm in baseball players, but showed opposite in non-baseball players.

Discussion: Higher coefficient of variation for EMG activity in TB in baseball batting suggests that TB muscles play a role in modulation of settling the arm or bat position in the sequence of coordinated muscle activity, beginning with the lower limb and terminating with the arms.

3-D KINEMATICS DURING INSTEP AND OUTSTEP SOCCER KICKS IN PUBERTAL PLAYERS

KATIS, A., KELLIS, E.

ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: The biomechanical characteristics of the instep soccer kick have been extensively studied (1,2). However, there are several types of kicks which are commonly used during a soccer game and have not received the appropriate attention.

PURPOSE

To examine the kinematic differences between instep soccer kick and kick with the outside portion of the foot (outstep kick).

METHODS: Ten pubertal soccer players (age: 13.6 ± 0.7 yrs, mass: 47.5 ± 13.1 kg, height: 153.5 ± 8.8 cm) performed 10 consecutive kicking trials in a random order after a two step angled approach with the instep and the outside portion of the dominant foot. The kick with the highest ball velocity was further analyzed. Bilateral three-dimensional kinematics in sagittal, coronal and transverse axis (six camera Vicon motion analysis system, 200Hz) were collected. The maximum ball speed, ball speed / foot speed ratio, segmental angular velocities and joint displacements were also estimated. A dependent Student t-test was used for comparisons between the two types of kick.

RESULTS: Significant ($P < 0.05$) differences in ball speed were observed between the instep (19.62 ± 1.89 m•sec-1) and the outstep soccer kick (18.55 ± 1.60 m•sec-1). Similarly, the ball/foot speed ratio was significantly ($P < 0.05$) lower for the outstep kick (1.52 ± 0.32) compared with the instep kick (1.63 ± 0.41). Non-significant differences in angular and linear sagittal kinematic parameters between the two types of kick were observed ($P > 0.05$) except the foot angular velocity which displayed significantly higher values during the instep kick ($P < 0.05$). In contrast, the outstep kick displayed higher hip abduction and internal rotation, internal knee rotation and ankle inversion ($P < 0.05$).

DISCUSSION: The present study indicated significant differences in the main biomechanical indicators of kicking success between the instep and the outstep kick. Similar results were reported for other types of kick (3) ranking the instep kick as the most powerful kick. During the outstep kick, the player needs to change the motion in the trunk-thigh, thigh-tibia and tibia-foot plane orientation in order to take the appropriate position for the kick. These changes seems to alter the proximal-to-distal transfer of energy between segments (4), thus leading to lower foot angular velocities and therefore lower ball speed values.

COMPARATIVE ANALYSIS OF ELITE FOOTBALL PLAYERS' THROW-IN

ZAHALKA, F., MALY, T., MALA, L., BUZEK, M.

CHARLES UNIVERSITY

Introduction: Lees and Nolan (1998) state that a throw-in is on the one hand a means of initiation of a game (a ball got out of playing field across a side line) and on the other hand it is a player's tactic skill. On professional level, but very often on amateur level, every team has its own specialist in throw-in on long distances, into opponents' penalty area. This way of throw-in in attack zone is more accuracy than long high pass of the ball.

Methods: The research group was n=13 (age = 20.28±0.91 years, height = 179.45±4.62 cm and weight = 76.15±3.72 kg). To evaluate the distance of the throw-in, 2D analysis was used; it was provided by one camera covering calibrated scope of 30m. 3 cameras were used for 3D spatial analysis of player's movement. The speed of the thrown ball was measured by means of a radar device STALKER ATS at the same time.

Results: The observed parameters of throw-in in the players show a longer distance (the length of throw-in) when throwing after a run up that in throwing from a standing position. In throw-in from a standing position an average value of the longest measured trials was xds = 20.19 ± 1.52 m. In throw-in after the run up, the distance of the throw was longer about 13.5 % when compared to throw-in from the standing position (xdr = 23.34 ± 2.75 m). In case of maximal velocity of the ball after the throw-in, the lower average speed was registered in throw-in from the standing position vs = 50.1 km/h than in the throw-in after run up vr = 53.9 km/h. The highest registered speed after throw-in from the standing position was vsmax = 56.2 km/h and the minimal speed was vsmin = 42.2 km/h. Variation coefficient of the speed of all trials is 6.6 %. When throwing-in after run up the maximal measured velocity was vrmax = 62.3 km/h and the minimal velocity was vrmin = 46.9 km/h. The performance of throw-in after run up is realized in two ways. In a symmetric way, both arms perform symmetric movement above a head in a final phase. In an asymmetric way, a trunk is more twisted. A non-dominant arm is shifted forward and a swipe is performed by a dominant arm. From totally 13 players, 7 players performed the throw-in asymmetrically and 6 players symmetrically.

Conclusion

Measured data show wider scope of values among several players. It proves different level of technical mastery of particular skill. Linthorne and Everett (2004) indicate variable velocity in various angle of the throw-in from the standing position in range 43.2 – 68.4 km/h in an experienced player. In training practice it is necessary to focus on improvement of performance of this skill and the choice of suitable way of the throw-in.

BIOMECHANICAL ANALYSIS OF HANDBALL THROWS IN TWO DIFFERENT PLAYERS

PSALMAN, V., DUVAC, I.

COMENIUS UNIVERSITY BRATISLAVA

INTRODUCTION Many sports and physical activities require different levels of abilities and skills. Accuracy and throwing velocity are basic parameters of sport performance in handball. Diagnostic process – monitoring of overarm throws by kinetic parameters with the help of 3 D biomechanical analysis is possible to achieve much more accuracy and different points of view.METHODS Two handball players in age 24 and 20 were observed in three throwing attempts by using two synchronized high speed cameras and Simi motion software. This 3D biomechanical analysis allows to find exact values of kinetic parameters.RESULTS All attempts of each player were similar, more differences appeared among tested players. Better results are tied with higher sport performance. Throwing technique is stabilized and throws of one player have very common characteristics. The interesting differences appeared among tested handball players but we could find some basic phases which have to be done in same or similar way. We obtained following average results for velocities in ball release time: dominant wrist=8,397 (7,719) m/s, dominant elbow=5,954 (5,548) m/s, dominant shoulder=3,047 (3,151) m/s. All this values of playing hand confirm the theory about increasing velocity and acceleration during the throw. The other hand is also useful for keeping optimal and well balanced body position, velocities are lower: undominant wrist=1,952 (2,322) m/s, undominant elbow=3,016 (2,399) m/s and undominant shoulder=2,485 (2,188) m/s. Excellent kinetic chain has to be connected with well balanced body position. The lower part of body must be also quiet enough. All throwing phases have to be very accelerated but smooth and players are able to do some movements corrections in time just before ball release phase (shoulder and elbow velocity decrease). Very interesting are high acceleration peaks in time about 0,04s before releasing ball but quite big differences exist in decceleration after this moment. The reason for doing this is accuracy of overarm throw.CONCLUSION The kinetic chain is a coordinated activation of the body segments which starts with legs, trunk, then follows to shoulders, elbows and ends with the acceleration of the wrist. Created three dimensional space is real and sufficient for understanding of each handball throw. Based on this biomechanical analysis it is possible to improve individual throwing technique which requires special individual training.

COMPARISON OF DYNAMIC AND STATIC BALANCE IN ADOLESCENTS HANDBALL AND FOOTBALL PLAYERS

AKAN, I., RAMAZONOGLU, N., UZUN, S., ATILGAN, O., ÇAMLIGUNEY, F., KUCUK, V., BOZKURT, S., TIRYAKI, C., SIRMEN, B.

MARMARA UNIVERSITY

Introduction: Handballers and soccer players require maintain balance as they run at high speed, change direction and powerfully throw and kick the ball to pass or shoot. Sport training programs may cause different balance abilities and these differences could be objectively measured using Center of Pressure Measurements (COP). The aim of this study was to compare static and dynamic balance between adolescent handball and soccer players.

Materials and Methods: Thirty two student national athletes: soccer (17), Handball (15) between 15-18 years of age and at least 3 training years were included to the study.

Assessment of static balance and dynamic balance was measured with Prokin 5.0 Technobody. The following tests were utilized: 1) Static tests were done as Opened Eyes (EO) and Closed Eyes (EC) with 30 second duration. Dynamic Tests 1) Slalom test was used as monoaxial dynamic-time test Forward-Backward (F-B) to one axis a time and to assess the subject's skill to complete the exercise. In this test, the subject tries to see some balls-objectives that come against. The subject's scope is to hit objectives and follow ideal line within 60 sn duration (a) hold with two hand and (b) without hold. Subject load was selected 5 hard degree (according to soft (0) to hard (10) degree system). 2) Unilateral dynamic-stance tests were done with the controlled load monoaxial test (F-B) for right and left foot. This test consists in a test where the subjects try to catch up two objectives with 10 repetitions on an axis controlling load (5 hard).

Results: Balance test evaluations between two groups compare with Mann Whitney-U test. There were no significant differences in EO Indexes Average C.O.P. X, EO Indexes Average C.O.P. Y, EO Indexes F-B Std. Dev., EO Indexes Medium-Lateral (M-L) Std. Dev., EO Indexes Average F-B Velocity, Indexes Average M-L Velocity and all dimensions for closed eyes (EC) between the two groups on static tests. Be-

sides, There were no significant differences between two groups on Romberg Test EC/EO Perimeter Ratio and Perimeter Area Ratio (p>0,05). No significant differences were found between two groups in dynamic tests; 1) slalom tests both holding with hands and without holding hands (p>0,05) 2) unilateral dynamic-stance tests for left and right foot between two groups (p>0,05). Within each group all parameters were compared between left and right foot perimeter error scores for unilateral F-B dynamic balance condition by Wilcoxon Test. For football players, significant differences were found between left and right foot (p<0,05). But, there is no significant differences for handball players (p>0,05).

Discussion: The main reason to that is dynamic balance is necessary and effective in the fundamental technical movements of the both sports (examples dribbling, throwing, kicking and faking). F-B dynamic balance was greater for left foot than for right foot for football players. The reason is that all of the footballers are dominantly using their right leg so left leg is the supporting leg.

EFFECT OF GROWTH AND DEVELOPMENT ON UPPER AND LOWER LIMBS MOVEMENT DURING THROWING IN BASE-BALL PLAYERS.

MIYAZAKI, M., YOSHIDA, S., IHARA, Y., TAKAHASHI, Y., TANAKA, S., TSUNODA, N.

J. F. OBERLIN UNIVERSITY

Purpose: The aimed of this study was to clarify the characteristic of upper and lower limbs movement velocities during throwing in base-ball players due to growth and development.

Methods: Seventy-nine male baseball players aged from 12 to 21 years old were requested in this study. These subjects were classified by chronological age. And also, they were divided 3 groups. (During adolescence: DA, 12-15 years, n=46, Post adolescence: PA, 16-19 years, n=21, Adult: AD: 20-21 years, n=12). The body height (BH) and body weight (BW) as body size parameters were measured in all the subjects. The maximal ball velocity of overarm pitched in a distances of 10.0m (BV) as a throwing performance was obtained by Radar-gun (Mizuno) in all the subjects. The throwing movement was recorded by two high-speed cameras and analyzed by computer with 3-D analysis software. The phase of throwing movement analyzed from the point of knee up position to ball release. Peak velocity of wrist joint (PVW), elbow joint (PVE), shoulder joint (PVS), hip joint (PVH), knee joint (PVK) and stride length (SL) on throwing movement were measured. Significant group differences between age group in each item were performed using ANOVA. Moreover, partial correlation coefficient and multiple regression analysis between peak velocity of each joint and pitched ball velocity were analyzed for all the subjects.

Results and conclusion: BV was increased due to age groups. Significantly higher value was showed in AD（33.8±1.9m/s）compared to other groups (DA:28.1±2.5m/s, PA:32.2±21.7m/s). SL was progressive increased from DA (1.05±0.09m) to AD (1.20±0.05m). SL per BH was relatively constant in all age groups (DA:66.6±5.0%, PA:66.9±3.4％, AD:69.3±3.2%). Significant partial correlation coefficient was obtained between BV and SL (rxy.z= 0.635, p<0.05) in DA. PVW, PVE and PVS were increased from DA to PA. However, PVH was increased from PA to AD. Significant partial correlation coefficient was obtained between BV and peak velocity of each joint in upper limbs in DA (PVW: rxy.z= 0.756, PVE: rxy.z= 0.628, and PVS: rxy.z= 0.371, p<0.05). And also, PVW were effect to BV in PA (rxy.z= 0.512 p<0.05) and AD (rxy.z= 0.695, p<0.05). Significant partial correlation coefficient was obtained BV and PVE in PA (rxy.z= 0.519, p<0.05). In lower limbs, PVH were effect to BV in DA (rxy.z= 0.494, p<0.05) and PA (rxy.z= 0.558, p<0.05). PVK weren't effect to BV in all groups.

From these results, it was considered that the effects of throwing movement velocities of upper and lower limbs on pitched ball velocity were differed by growth stage in young baseball players.

MUSCLE ACTIVITIES OF THIGH DURING 100M SPRINT IN TRACK AND FIELD ATHLETES EXPERIENCED HAMSTRINGS MUSCLE STRAIN INJURY.

KOBAYASHI, M., GAKUHARI, H., KANEHISA, H., AOYAMA, T., TUNODA, N.

KOKUSHIKAN UNIVESITY

It is not clear that the profiles of muscular activities during 100 m sprint running in relation to the occurrence of muscle strain injury. The present study aimed to investigate the profiles of muscle activities of thigh during 100 m sprint running in track and field athletes experienced hamstrings strain injury, with specific emphasis on the difference between injured and uninjured legs. The subjects were 18 track and field athletes. Of the subjects ten had experienced hamstrings muscle strain injury (MS, 5 males and 5 females) and the remainder was classified as a non-muscle strain injury group (NMS, 4 males and 4 females). The electromyograms (EMGs) of thigh muscles (the biceps femoris, semitendinosus, rectus femoris, vastus lateralis and vastus medialis) and knee joint angles were recorded during the 100 m sprint. The EMG activities and knee joint angles were analyzed in the three phases of 100m sprint; acceleration (30~50m), maximum speed (50~70m) and deceleration (80~100m) phases. The average integrated EMG (iEMG) value of each phase was expressed as relative to that of the maximum voluntary contraction (%mEMGMVC). In the ground contact phase and the swing phase during running cycle, the maximum value of the knee joint flextion angle was determined. The NMS group did not show significant difference between left and right legs in the muscular activities for all muscle groups and maximum knee joint angles in each phase. In injured leg of MS group, the %mEMGMVC values of the biceps femoris and semitendinosus in the acceleration and maximum speed phases were significantly higher than those of uninjured leg. Also, the maximum knee joint angles for the injured leg were significantly lower as compared to the uninjured leg. The observed differences in the muscular activities between injured and uninjured legs may be assumed to be due to the corresponding difference in the strength capability of hamstring muscles. Also, the results of the knee joint angle were suggested that effected on the muscle activity level and muscle fatigue. The present study indicated that track and field athletes experienced muscle strain injury show different muscular activities between injured and uninjured legs in 100 m sprint running. It is difficult to conclude whether running form and muscle activity is related to the main cause of muscle strain injury. However, the finding obtained here will be a reason for high recurrence rate of muscle strain injury.

ISOMETRIC SURFACE EMG FATIGUE EVALUATION IN FEMALE ROWERS

UZUN, S., ŞAYLI, Ö., TATAR, Y., ÇOTUK, B.

MARMARA UNIVERSITY

Introduction: Methods for assessing the electrical manifestations of muscle fatigue during isometric, constant-force contractions are reported in many studies. Relatively few studies were carried out to quantify muscle fatigue resulting from isometric contractions in elite female athletes.

Purpose: We aim to evaluate isometric conditioning and fatigue profile with 30 second duration isometric exercise using surface electromyography (SEMG) in female elite rowers.

Method: The subjects are composed of a total of twelve healthy female athletes between 16-21 years of age. The Vastus Lateralis (VL) muscle of the dominant leg was chosen for the recordings. Although, in all subjects the dominant extremity was the right leg, for only one subject, the experiment was carried out with the left leg because she had a meniscus injury in her right leg. Experimental set up was designed in accordance to the rowing sport. While the hip joints for all the subjects were brought to a 100 degree flexion, the knee joints were brought to a 90 degree flexion. The range of the knee joint angle (15) during the movement was set from 90 to 105 degree for each subject.

The Maximum Voluntary Contraction (MVC) force was determined using the instrumentation set up within a few trials. The maximal value of MVC was used as the reference value to determine a load of 80 % of MVC for each subject. For isometric contraction the subjects managed to close the spring. SEMG data were recorded from the VL muscle with Ag-AgCl surface disk electrodes according to the recommendation by SENIAM. SEMG signal was increased 1000 times using a differential amplifier and filtered through an analog band pass filter between 5-500 Hz at 2000Hz sample rate. The median frequency (MDF) and the mean frequency (MNF) of the power spectrum and Root Mean Square (RMS) were computed for the SEMG signal.

Results: Initial and final values of MDF, MNF and RMS of elite female rowers were compared by wilcoxen test. Significant decrease was found between initial MDF (mean: 105.60) and final MDF (mean: 95.61) of subjects ($p<0.01$), in the same way, significant decrease ($p<0.01$) was found between initial MNF (mean: 124.18) and final MNF (mean: 112.99) of subjects. In this experiment, significant decrease ($p<0.01$) was found between initial RMS (mean: 141.03) and final RMS values (mean: 96.59).

Discussions: Shift in MNF and MDF is well known in the literature during fatiguing contractions. The reasons are the conduction velocity decrease and synchronization between different motor units in the muscle. In contradiction to the RMS increase reported in the literature for sustained isometric contractions, decrease is found in all the subjects who could reflect some underlying strategy for muscle load sharing in these female athletes. As a result, there should be further research for the SEMG fatigue evaluations for different muscle groups and contraction types on female athletes.

EFFICIENCY PARAMETERS OF ENDURANCE ATHLETES WHILE JUMPING

BOULLOSA, D., TUIMIL, J.L.

FACULTY OF PHYSICAL ACTIVITY AND SPORT SCIENCES

Introduction: There is controversy about the rate of force development (RFD) when examining explosive force in dynamic conditions. Its relevance in complex dynamic exercises could be masked by some different factors as its influence in isometric conditions has been extensively demonstrated (Aagaard et al., 2002). Thus, our purpouse was to evaluate kinetics while jumping (CMJ) in a cohort of well trained endurance athletes as they have some homogeneous anthropometric and neuromuscular characteristics that could facilitate the study of selected parameters.

Methods : 14 male endurance athletes (8 middle-distance runners and 6 triathletes) performed in a force plate (500 Hz) two attempts of CMJ after a warm-up. The depth of countermovement was freely choosen by participants.The best jump was selected for further analysis. The kinetic parameters selected were: peak power (PP), mean power (MP), peak RFD (pRFD), and vertical stiffness (Kvert).

Results: Significant correlations were found between: pRFD and PP (r = 0,544; p=0,044); pRFD and Kvert (0,693; p=0,006); Kvert and MP (r = 0,808; p=0,000); and Kvert with PP (r = 0,756; p=0,002).

Discussion: Correlations between Kvert and power measurements suggest an elastic energy transfer between eccentric and concentric actions (Bosco et al., 1982). The novel correlations between RFD and PP suggest an indirect influence of RFD in CMJ performance as PP is highly related to CMJ height. The relationship exhibited between Kvert and RFD, as both are very close in time during force recording, could suggest a reflex origin of this RFD based on previous assumptions (McBride et al., 2008).

COMPLEX SYSTEMS EVALUATION OF FATIGUE BASED ON ECG INTERCONNECTED PARAMETERS

VAINORAS, A., VENSKAITYTE, E., BALAGUE, N., PODERYS, J., BERSKIENE, K.

1. KMU (KAUNAS, LITHUANIA), 2. INEFC (BARSELONA, SPAIN), 3. LAPE (KAUNAS, LITHUANIA), 4. KTU, IBME (KAUNAS, LITHUANIA)

Introduction: Dynamic processes are evident trough the complex fluctuations of physiologic output signals such as those appearing in the ECG. Interconnections of different ECG parameters based on matrix theory (Vainoras et al., 2008) have been determined during a modified Rufje exercise test. The aim of this investigation was to evaluate the dynamics of different fractal levels of inter-parameter interactions in the ECG and to establish new features to assess fatigue.

Methods: 14 elite Lithuanian Greco Roman wrestlers participated in the study performing a modified Rufje exercise test in 4 stages of the investigation protocol: 1st day before trainings and after 1st and 2nd training, and 2nd day before trainings. The „Kaunas-load" ECG analysis system has been used for the evaluation (Vainoras, 1997). The interconnection of different ECG parameters representing different fractal levels (heart, organism) have been studied in the different stages.

Results: The interactions of ECG parameters and its dynamics at different fractal level varied respectively to the stage of investigation. The dynamic of interconnections during the beginning of 1st and 2nd day was similar – the change of interconnection was increasing during load at heart level. In both days the results after the 1st and 2nd training, respectively, show how interconnections at the organism level

differ significantly (P>0,95), showing an increase in the fluctuations with fatigue. This significant change also depends on the sportsmen level and experience.

Discussion: New features of fatigue have been revealed as the tendency to present altered values of inter-parameter relationships in post-training monitoring. These results are in agreement with the finding that the process of fatigue is related to the interaction between functional systems (Nybo, 2008). Summing-up the evaluation of the interconnection between ECG parameters representing different fractal levels allows the detection of fatigue features.

VIBRATION EXERCISE: AN EFFECTIVE COUNTERMEASURE FOR VASCULAR ADAPTATIONS TO BED REST

VAN DUIJNHOVEN, N., THIJSSEN, D., GREEN, D., FELSENBERG, D., BELAVÝ, D., HOPMAN, M.

DEPARTMENT OF PHYSIOLOGY, RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE, NIJMEGEN, THE NETHERLANDS

Introduction: Physical deconditioning is an important independent risk factor for atherosclerosis and cardiovascular disease. While bed rest results in marked vascular changes, exercise has shown to be an effective countermeasure for these adaptations (Bleeker et al, 2005). However, little is known about the most optimal exercise type to prevent the vascular changes to bed rest. Therefore, the purpose of this study was to examine the effect of two different types of exercise, i.e. resistive exercise and resistive vibration exercise, to counteract the vascular adaptations to bed rest.

Methods: Eighteen healthy men (31±8 years) were randomly assigned to bed rest (control; C), bed rest with resistive exercise (RE), or bed rest with resistive vibration exercise (RVE). Exercise was applied three times a week for 5-7 min per session. Before and after 60 days of bed rest, resting diameter and blood flow, flow-mediated dilation (FMD; a measure of endothelial function), and maximal diameter of the superficial femoral artery (SFA) were measured using echo Doppler ultrasound.

Results: After 60 days of bed rest, resting diameter of the SFA was significantly decreased in C and RE (Wilcoxon: P=0.02 and 0.04, respectively), but not after RVE. No changes in resting and hyperaemic blood flow were found after bed rest in all groups. While FMD increased in C and RE (P=0.02 and 0.04, respectively) after bed rest, FMD did not change in the RVE-group. C and RE showed a decrease in maximal SFA diameter (P=0.02 and 0.04, respectively), while maximal SFA diameter was preserved in the RVE-group. Using ANCOVAs, we identified significant group effects for resting diameter and FMD (P=0.02 and 0.003, respectively), but not for maximal diameter.

Discussion: 60 Days of bed rest deconditioning is accompanied by a decrease in resting and maximal diameter of the SFA, and an increase in FMD. The stimulus provided by resistive exercise was insufficient to counteract the vascular adaptations to bed rest. However, adding a vibration component to the resistive exercise, significantly attenuated or even preserved the changes in superficial femoral artery diameter and endothelial function to bed rest. In conclusion, only three, ~6-min resistive vibration exercise bouts per week during bed rest is suitable to counteract the detrimental vascular adaptations to bed rest.

THE EFFECTS OF REGULAR EXERCISE ON THE CARDIAC AUTONOMIC NERVOUS ACTIVITY IN RECOVERY PHASE AFTER ANAEROBIC INTERVAL EXERCISE

ONO, K., OGAWA, M., KITAGAKI, K.

KOBE UNIVERSITY

Introduction: It has been suggested that the collapse of the autonomic nervous system is related to sudden death. It has become clear that high activity of the parasympathetic nervous system causes a decline in the death rate. The purpose of this study was to determine the effects of regular exercise on cardiac autonomic nervous activity in the recovery phase after anaerobic interval exercise.

Method: Twenty four healthy young people (11 males: age: 20.3±0.67years; Mean ± S.D., height: 169.67±3.59cm, body weight: 59.89±3.53kg, % body fat: 16.46±1.92% and 13 females: 20.7±5.37years, 159.9±40.46cm, 52.63±14.36kg and 25.97±7.92%: T-group) and 26 young people (12 males: 21.6±1.06years, 173.0±4.67cm, 62.1±6.22kg and 18.1±3.18% and 14 females: 21.6±0.87 years, 157.0±4.21cm, 48.0±4.69kg and 27.0±3.69%: S-group) participated in this study, voluntary. The subjects ran up 23 steps with theirs best, and they had interval for 20 seconds. They repeated up to 80% HR reserve. After exercise, they had recovered for 30 minutes by supine position. The measurements were Augmentation index (AI) and central systolic blood pressure (c-SBP) on rest, heart rate (HR) and cardiac autonomic nervous activity (low frequency: LF and high frequency: HF) on rest and after exercise (immediately, 5, 10, 15 and 30min.), respectively. The temperature and humidity were 25.3±0.98ºC and 47.3±4.11% during measuring, and they were 19.3±0.25ºC and 45.6±1.69% during exercise.

Results: The T-group's AI on rest was 64.9±14.0, and the S-group's was 55.7±9.10. The T-group's c-SBP on rest was 112.17±9.99mmHg, and the S-group's was 104.7±10.26mmHg. The T-group's HR on rest was 57.1±6.85bpm, and S-group's was 68.7±11.31bpm. The T-group's log HF on rest was 3.33±0.49, and S-group's was 3.05±0.36. The results revealed that the T-group's HR on rest led to a significant reduction and AI, c-SBP and log HF led to a significant high value compared with on S-group's (P<0.05), respectively. The T-group's HR at the 30 minutes on recovery phase was 70.9±9.59bpm and the S-group's was 81.9±4.67bpm. The T-group's HR got back early

significantly to S-group at the 30 minutes on recovery phase (P<0.05). The changes of the parasympathetic nervous activity with recover were not significant between T-group and S-group. The T-group's log HF on every measuring timings showed higher than S-group (P<0.05). Both the T- and S-group's log LF/HF showed high value till 5 minutes on recovery phase (P<0.01).

Discussion/Conclusion

It was suggested that cardiac parasympathetic nervous activity play a role in trained people's reduction of HR on rest and early recovery of HR after anaerobic exercise. It was suggested that a regularly exercise had rise cardiac parasympathetic nervous activity after anaerobic exercise.

THE EFFECT OF ENDURANCE EXERCISE AND SIRT ACTIVATION ON BRAIN FUNCTION IN RATS ARTIFICIALLY SELECTED TO HIGH OR LOW RUNNING CAPACITY

SÁRGA, L., HART, N., KOLTAI, E., NYAKAS, C., FELSZEGHY, K., BRITTON, S., KOCH, L., LAMBERT, P., RADAK, Z.

SEMMELWEIS UNIVERSITY

Sirtuins are NAD+ dependent protein deacetylases and suggested regulators of aging, fat and sugar metabolisms, DNA repair, mitochondrial biogenesis and brain function. Resveratrol, a potent activator of SIRT1 has been shown to reduce plaque pathology in transgenic model of Alzheimer diseases. In addition, it is well documented that regular exercise enhances performance at number of tests including Morris maze and passive avoidance tests. In the present study we trained selectively bred 24 generations for intrinsic aerobic high running capacity (HCR) or low running capacity (LCR) rats and some groups were supplemented by SIRT activator for 4 month. We measured balance using Rotarod test and found the benefical effects of exercise training. The behavior of the animals was assessed by open field tests, in which exercise trained HCR rats with SIRT activator supplementation showed higher level of interest to explore the new environment. Interestingly enough, on the other hand, when we checked the new object recognition, LCR rats had better performance. We also observed, that exercise training resulted in better performance at passive avoidance test. The biochemical analysis of hippocampus suggest that some of the beneficial changes in the brain could be mediated through brain derived neurotrophic factors which was induced by running exercise.

Our data show, that the brain performance of LCR and HCR rats not significantly different, when it is assessed by passive avoidance, new object recognition tests. On the other, hand exercise training beneficial for both groups.

PHYSICAL ACTIVITY INTENSITY, HEART RATE, BLOOD LACTATE CONCENTRATION AND RPE DURING 5-KM MEN'S AND 3-KM WOMEN'S INDOOR RACE WALK

VERNILLO, G., AGNELLO, L., DRAKE, A., FIORELLA, P.L., LA TORRE, A.

FACULTY OF EXERCISE SCIENCES, MILAN UNIVERSITY, ITALY

INTRODUCTION: Physical training is the systematic repetition of physical exercises and it can be described in terms of its outcome (anatomical, physiological, biochemical, and functional adaptations) or its process; that is, the Training Load (TL) (the product of volume and intensity of training). Nowadays, there have been several attempts to quantify TL, such Heart Rate (HR), Blood Lactate Concentration ([La]) and Rate of Perceived Exertion (RPE)[1, 2]. Race Walking (RW) is the technical and athletic expression of fast walking and it can be considered an endurance performance. Despite its centuries-old history few studies have investigated the physiological profile of the race walkers and, moreover, no study has analyzed both the physical activity intensity and the physiological stresses during a race. Thus, this study classified the intensity of the 5-km men's (5M) and 3-km women's (3F) Indoor RW (IRW) and examined both HR, [La] and RPE responses in the two races and the possible relationship between the above mentioned variables in order to verify the Internal Load (IL) of the athletes.

METHODS: 11 race walkers, 5 male (mean age: 30,2±3,4 yrs; height: 174,6±3,5 cm; weight: 63,2±5,9 kg) and 6 female (mean age: 22,3±3,6 yrs; height: 167,2±3,3 cm; weight: 53,2±2,2 kg) were enrolled in this study. During the Italian Athletic Indoor Championship held in Turin in February 2009, HR was recorded to establish the HRmean; after the performances [La] and RPE (Borg 6-20 scale) were registered. HRmean was set as a percentage of the mean predicted maximal heart rate to quantify, with the RPE, the possible physical effort of the disciplines. Therefore, both for 5M and 3F, HRmean, [La] and RPE were standardized with each data point transformed to a z score [z=(raw score–mean)/SD] using the variable specific grand mean and SD. Means for standardized values were then compared using repeated-measures ANOVA. Results were considered significant at p=0.05.

DISCUSSION/CONCLUSION

HRmean and the RPE show that both the 5M and 3F present a very hard intensity profile[2], suggesting that the physiological model of the two disciplines might be aerobic-power-oriented. No statistical differences (p>0.05) were found between the HRmean, [La] and RPE in the two groups; that means in the IRW there might not be a more appropriate tool to evaluate the IL of the athletes; thus the three means seem to be able to measure, indirectly, the IL during an IRW race and the choice might be attributed to the specific knowledge and/or techniques available to the coach. However, considering the low number of the athletes involved, further studies should be conducted to outline the most suitable tool to assess the IL in the IRW.

ACHIEVEMENT GOAL ORIENTATIONS OF YOUNG MARTIAL ARTISTS

VERTONGHEN, J., THEEBOOM, M.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: To date, contrasting images seem to appear regarding the effect of martial arts involvement. While some studies reported an increase of antisocial behaviour among young martial artists, others described positive social-psychological effects.

To make general statements with regard to the socio-psychological outcomes of sports participation, Shields and Bredemeier (1995) indicated several influential factors have to be taken into account. The present study focuses on the influence of the differences of participants' characteristics.

One of the differences could refer to the specific behaviour of the participants (e.g., how self-confident, aggressive, … is someone). Another difference of participants' characteristics reported in the literature relates to the achievement goal orientations of the martial artists.

Two studies examined whether the achievement goal orientations vary as a function of the type of martial art. Gernigon and Le Bars (2000) stressed the compatibility of a competitive context and task orientation, whereas King and Willams (1997) stressed the compatibility of traditional martial arts and task orientation. Building on these findings a hypothesis, which will be investigated in the present study, is formulated: "Children participating in a harder martial art (e.g., kick-thaiboxing), where a modern approach is used, will be more ego oriented, while children practising a softer martial art (e.g., aikido), where a traditional approach is used, will be more task oriented.'

The purpose of the present study is to make a behavioral screening of the young martial artists and to examine the achievement goal orientations of the children.

METHODS: 120 children between the age of 10 and 16 years who practised aikido, judo or kick-/thaiboxing in a sporting club located in Flanders and the Netherlands were interviewed. The young martial artists were asked to respond to a Dutch version of the Perception of Success Questionnaire to measure the achievement goal orientations and their parents were asked to respond to a Dutch version of the Strength and Difficulties Questionnaire to make a behavioral screening of the children.

DISCUSSION: Findings revealed, among other things, that the type of martial art that is practiced has an influence on the achievement goal orientations of the participants, which on his turn has an influence on the youngsters' experiences. However, other aspects should be taken into account when examining the experiences of young martial artists, such as the type of guidance or approach used by their martial arts teachers.

DESIRED SUPPORT TOWARDS PHYSICALLY MORE ACTIVE LIFESTYLE IN FINNISH MIDDLE-AGED MEN

Maijala, H-M., Lähdesmäki, A., Hakonen, H., Komulainen, J., Rovio, E., Havas, E.

LIKES Research Center for Sport and Health Sciences, Jyväskylä

Finland

Introduction: To encourage people to be physically more active is a major challenge in modern societies. In order to be successful, the promotion of physical activity requires understanding of the desired support of different groups. The middle-aged men represent one of the least physically active groups in Finland. The aim of this study was to gather detailed information on factors that may support physical activity promotion efforts in this group of population.

Method: The data was collected from a group of men (n=607) who participated in a physical activity promotion tour (Adventures of Joe Finn -campaign) during spring 2008. The men, who were aged 25-64, answered questions about their physical activity levels and attitudes towards physical activity. According to their socio-economic status, the men were divided into blue-collar workers (51%) and others (49%). The age deviation of the group matched well the general population, but the group was slightly less active than Finnish men on average, when measured in frequency of leisure time physical activity.

The men were asked about supporting factors towards physically more active lifestyle (a total of 9 answers, multiple answers possible). According to the men's physical activity levels, three subgroups were created; low activity (at least 30 min exercise, ≤ 1 time a week, n=196), intermediate activity (at least 30 min exercise, 2-3 times a week, n=223), and high activity (at least 30 min exercise, ≥ 4 a week, n=119).

Results: Regardless of their physical activity level, the men mentioned the same supporting factors. The most mentioned supporting factors in the low activity group were support from spouse/family/friends (78%), prospect of more leisure time (71%), and social type of exercise (70%). In the high activity group, support from spouse/family/friends and prospect of more leisure time (both 81%) were mentioned the most frequently. Only 21% of the low activity group and 48% of the high activity group desired for competitive activity. 35% of the low activity group and 50% of the high activity group would appreciate materials as supporting factors. In addition to activity levels, the socio-economic status did not affect the desired support significantly.

Discussion: According to this study, physical activity level or socio-economic status do not have sufficient influence on desired support towards physically more active lifestyle. The findings of the study suggest that in order to increase physical activity and behavioural change, the social micro-environment of a person is essential. More information about a target group and its desired support can be used as evidence based platform for planning future policies and efforts to increase physical activity.

PHYSICAL ACTIVITY OF GIRLS - SOCIALIZATION PROCESSES IN ELITE ARTISTIC GYMNASTICS

ZURC, J.

UNIVERZA NA PRIMORSKEM, UNIVERSITA DEL LITORALE

INTRODUCTION: The aim of research was studied the consequences of participation in elite women's artistic gymnastics. The attention was put at the children, who were in the top of Olympic Games competitions in period from 1972 to 1988. The treated period was marked with the youngest competitors in women's artistic gymnastics in entire history of the gymnastics Olympic competitions.

METHODOLOGY: The research was carried out with anthropological methodology approach. The data was collected in media articles, interviews, shows, documentaries and autobiographies in all countries, from where Olympic champions came. Qualitative analyses were made with statements of journalist, public, parents and gymnast themselves.

RESULTS: The results pointed out, that there exist sport abuse behaviours in elite women's artistic gymnastics in the Olympic period from 1972 till 1988. There are evidences about emotional and physical abuses during the training and competitions (the most often caused from trainers), falsification of personal data of gymnast (from nation federations) and presence of eating disorders and anxiety during or after sport carrier. Injuries on one side and winning at the Olympic Games at the other side were the most popular reasons for leaving the elite gymnastics carrier.

CONCLUSIONS

Women's gymnastics in seventies and eighties was sport for children. The central meaning was put to achieve the biggest international trophies for any price. With intention to avoid such abuses of children in elite sport in the future is urgently to raising the age limitation for the senior artistic women's gymnastics competitions to the majority, like is usual praxis in other Olympic competitive sports.

A WEARABLE SYSTEM TO TIME GATE CROSSING DURING ALPINE SKIING SLALOM

CHARDONNENS, J., FAVRE, J., CATTIN, S., JOLLES, B.M., GREMION, G., AMINIAN, K.

1. ECOLE POLYTECHNIQUE FÉDÉRALE DE LAUSANNE, 2. FISCHER SPORTS GMBH, 3. CENTRE HOSPITALIER UNIVERSITAIRE VAUDOIS & UNIVERSITY OF LAUSANNE

INTRODUCTION: In alpine skiing, chronometry analysis is currently the most common tool to assess performance. It is widely used to rank competitors during races, as well as to manage athletes training and to evaluate material. Usually, this measurement is accurately realized using timing cells. Nevertheless, these devices are too complex and expensive to allow chronometry of every gates crossing. On the other side, differential GPS can be used for measuring gate crossing time (Waegli et al). However, this is complex (e.g. recording gate position with GPS) and mainly used in research applications. The aim of the study was to propose a wearable system to time gates crossing during alpine skiing slalom (SL), which is suitable for routine uses.

METHODS: The proposed system was composed of a 3D accelerometer (ADXL320®, Analog Device, USA) placed at the sacrum of the athlete, a matrix of force sensors (Flexiforce®, Tekscan, USA) fixed on the right shin guard and a data logger (Physilog®, BioAGM, Switzerland). The sensors were sampled at 500 Hz. The crossing time were calculated in two phases. First, the accelerometer was used to detect the curves by considering the maximum of the mediolateral peak acceleration. Then, the force sensors were used to detect the impacts with the gates by considering maximum force variation. In case of non impact, the detection was realized based on the acceleration and features measured at the other gates. In order to assess the efficiency of the system, two different SL were monitored twice for two world cup level skiers, a male SL expert and a female downhill expert.

RESULTS AND DISCUSSION: The combination of the accelerometer and force sensors allowed to clearly identify the gate crossing times. When comparing the runs of the SL expert and the downhill expert, we noticed that the SL expert was faster. For example for the first SL, the overall difference between the best run of each athlete was of 5.47s. At each gate, the SL expert increased the time difference slower at the beginning (0.27s/gate) than at the end (0.34s/gate). Furthermore, when comparing the runs of the SL expert, a maximum time difference of 20ms at each gate was noticed. This showed high repeatability skills of the SL expert. In opposite, the downhill expert with a maximum difference time of 1s at each gate was clearly less repeatable. Both skiers were not disturbed by the system.

CONCLUSION: This study proposed a new wearable system to automatically time gates crossing during alpine skiing slalom combining force and accelerometer sensors. The system was evaluated with two professional world cup skiers and showed a high potential. This system could be extended to time other parameters.

INFLUENCE OF WORKLOAD AND POSTURE ON HANDCYCLING EFFICIENCY

GAFFURINI, P., GOBBO, M., BISSOLOTTI, L., CALABRETTO, C., ORIZIO, C.

LABORATORY OF NEUROMUSCULAR REHABILITATION (LARIN), UNIVERSITY OF BRESCIA/DOMUS SALUTIS CLINIC

Introduction: Handbike (HB) is an arm propelled device of locomotion for subjects with lower limbs disabilities. Handcycling has become a Paralympics discipline, increasing the need to study how lesion level may influence posture on HB and energy cost during exercise. The aim was also to test how postures different from the free chosen one might influence functional parameters during exercise.

Methods: We studied 20 handbikers: 14 DivB (lesions T1-T10), 6 DivC (lesions T11-L5). The HB was placed on a computerized roller to measure speed (km/h), frequency of revolutions (rpm) and power (Watt). The arm-crank unit was equipped with a load cell to measure horizontal (Fh)/vertical (Fv) forces and an infrared encoder to transduce angular position (15° resolution). VO2 and VCO2 were measured by a portable metabolic system Cosmed K4 b2 and heart rate (HR) by Polar monitor. The main muscles involved in cranking (Biceps Brachii, Triceps Brachii, Deltoid Anterior, Trapezius, Latissimus Dorsi) were studied by a portable EMG system.

1) The subject sat on the HB and chose his favourite posture (seat-crank distance and adjustable backrest inclination). The elbow angle (α) was measured when crank was in 90° position (maximal arm extension during cranking).

2) The athlete was asked to cycle at 65 rpm with 3 different chain gears: L1, L2, L3, corresponding to 32x28, 32x21 and 32x16 gear ratios, respectively.

3) The gear ratio determining 60-70% of HRmax, named threshold gear (Lt), was used to test two other positions with elbow angles of α+10° and α-10°.

Each bout lasted 4 min. Averaged Force and EMG envelope profiles were derived for a complete revolution.

Results: The increase of external workout from L1 to L3 determined an increase of both Fh and Fv. In particular, an increase of about 100% and 60% of Fh in DivB and DivC, respectively, took place. EMG activity in DivC increased less than in DivB subjects to obtain the same increase of external workload from L1 to L3. Considering exercise at Lt, no variations in EMG envelopes were founded passing from α-10° to α+10°. An increase in Fh was observed only in DivB group from α (41.2±21.6 N) to α+10° (56.9±27.5 N). VO2 was influenced by posture changes only in DivC: higher values for α-10° and α+10° than α position (α-10°: 23±7.5; α+10°: 22±6.9; α: 20±6.7 ml/kg•min).

Discussion: The different increase of both Fh and EMG with incrementing workload suggests different biomechanics and muscle recruitment in the two groups. Indeed, DivC subjects can recruit abdominal muscles leading to a higher exercise efficiency.

The increase of energy cost in DivC for α-10° and α+10° cranking positions, without concomitant changes in force and EMG, indicates lesser efficient postures compared to the free chosen one. For DivB, the more stable α+10° position determines even a more advantageous biomechanical condition, that is probably not spontaneously adopted by the subject for the uncomfortable sustained flexion of the head required to look forward.

THE WATERBASKET PLAYED BY MEN YOUTH PLAYERS: A HEART RATE, LACTATE, AND STRENGTH PROFILE.

LUPO, C., TESSITORE, A., BENVENUTI, C., AMMENDOLIA, A., RIZZATO, F., CAPRANICA, L.

UNIVERSITY OF ROME - FORO ITALICO

Intruduction

Waterbasket is a new team sport (Italian Waterbasket Federation, FISBA) during which two teams of 5 players compete four 10-min quarters on a 16x8m pitch with two baskets located at 1.5 m above the water surface. Every basket scored during the game is assigned 2 points, while 1 point is given when a free throw is scored (FISBA, 2005). To provide meaningful information for trainers interested in the development of waterbasket competitions, this study aimed to assess the intensity of efforts playing waterbaskeet matches.

Methods: Heart rate (HR) responses of 10 male waterbasket players (17±1yrs; height: 1.79±0.09m; weight: 74±15kg; BMI: 23±3 kg/m2; VO2max 57±6 ml.kg-1.min-1) were recorded with a sampling frequency of 5 s during a friendly match. Determinations of blood lactate (La; Accusport, Roche, Basel, Switzerland) were performed before the match, after the 2nd quarter, and at 3, 6, and 9 min of the recovery phase. Grip strength was measured (Lode, Groningen, The Netherlands) before and after the match. Intensity of effort was according to four categories: 1) maximal effort (>90% HRmax); 2) high-intensity (81-90%, HRmax); 3) moderate-intensity (71-80%, HRmax); 4) low-intensity (≤70% HRmax). ANOVA for repeated measures was used to test differences ($p<0.05$).

Results: Differences for HR emerged only for intensity effort ($p<0.0001$). In particular, during the waterbasket match, 7%, 24%, 55%, and 14% of the total duration were performed at ≤70%, 71-80%, 81-90%, and >90% of the individual's HRmax, respectively. Differences ($p=0.0008$) emerged for La, with highest values registered at the end of the 2nd (4.2±1.6 mmol•l-1, p=0021) and 4th quarter (4.6±2.2 mmol•l-1, p=0004). The comparison of the handgrip strength showed no difference between values recorded before (right hand: 460±78N; left hand 426±64N) and after (right hand: 465±102N; left hand: 430±61N) the match.

Conclusions: The present findings show that waterbasket matches impose a high load on the players, comparable to that reported in young elite basketball (Apostodolis et al., 2003) and elite water polo (Smith, 1998) players. Despite the HR response was greater than 80% of HRmax for 70% of game and peak La values were higher than the lactate threshold, players maintained their strength throughout the match.

ACUTE EFFECT OF STRENGTH EXERCISES WITH AND WITHOUT WEIGHT BELTS IN YOUNG RHYTHMIC GYMNASTS

BATTAGLIA, C., BALDARI, C., GUIDETTI, L., CIAPPETTA, F., DI CAGNO, A.,2

1. DEPARTMENT OF HEALTH SCIENCES, UNIVERSITY OF ROME "FORO ITALICO" , ITALY, 2. DEPARTMENT OF HEALTH SCIENCES, UNIVERSITY OF MOLISE, CAMPOBASSO, ITALY

Introduction For many years, young athletes were not expected to incorporate weight training into their overall training programs, and coaches did not put an emphasis on this type of preparation. Retrospective reviews found that weight training can be a safe and effective method of conditioning (Faigenbaum et al., 1996). The aim of this study was to assess if a single session of strength conditioning using weight belts could have a positive influence on leaping ability in young rhythmic gymnasts. Methods Twenty pre-puberal rhythmic gymnasts (age 12±1.6 years) were recruited for this study. The sample was divided into 13 cadets (age 11±0.9 years), and 7 juniors (age 13.7±0.8 years) competing at regional and national level. The gymnasts underwent two testing sessions in which three vertical jumps (Squat Jump, Counter Movement Jump, and Hopping Test) and three technical leaps (Split Leap with Leg Stretched - SL, Split Leap with Ring - R, Split Leap with Back Bend of the Trunk - BBT) were assessed in two conditions: after 15-minute of rhythmic specific strength exercises with and without weight belts at 6% of body mass (Faigenbaum et al., 2006). Leap performances in each of the two types of conditioning exercises were simultaneously evaluated through the Optojump System (focusing on flight time and ground contact time parameters) and by three rhythmic gymnastics judges (score). Results The main effects of categories (cadet and junior) and strength conditioning session (with and without weight belts) on dependent variables (vertical jump and technical leap ground contact time and flight time) were examined by a MANOVA with repeated measures on the second factor (p≤0.05). Two factors ANOVA assessed the effect of conditioning and categories on leaping performance evaluated by judge scores (p≤0.05). The analyses revealed no significant main effect on jumping performance of strength conditioning session. Significant differences between categories were found for flight time in R after strength exercises with weight belts (cadet 425±40.4ms; junior 464±17.2ms; $p<0.05$); in BBT after exercises with and without weight belts (cadet 429±26.7ms; junior 459±11ms; $p<0.01$; 427±32.8ms; junior 457±16.8ms; $p<0.05$, respectively). No differences were found in vertical jump performance. The judge evaluation was not affected by the protocols of the single session strength conditioning. Discussion A single session of conditioning with weight belts did not modify the jumping and leaping performance in young rhythmic gymnasts, likelihood because the eventual positive effect was counterbalanced by the negative effect of fatigue due to the exposure to unusual dynamic preloads exercises (Duthie et al. 2002).

PLASMA GHRELIN RESPONSES TO PROLONGED SCULLING IN MALE COMPETITIVE ROWERS

PURGE, P., JÜRIMÄE, J., RÄMSON, R., MÄESTU, J., JÜRIMÄE, T., VON DUVILLARD, S.P.
UNIVERSITY OF TARTU

The aim of the present investigation was to investigate plasma ghrelin responses to a single endurance rowing training session in male comüpetitive single scull rowers. Nine national standard male rowers (20.1±1.5 years, 183.9±4.3 cm, 81.0±5.0 kg, body fat%: 10.8±3.3%) volunteered for this study. The participants completed two 2.5 h trials (exercise or control) on separate days. The exercise trial involved a prolonged rowing training session lasting about 2 h (7373±129 s, distance covered 20.7±1.4 km, heart rate 133±4 bpm, intensity 80.2±1.6% of anaerobic threshold) followed by 30 min rest. The control trial consisted of 2.5 h of rest. Venous blood samples were obtained at 0, 2.0 and 2.5 h. No differences were found between baseline values for measured plasma ghrelin and leptin concentrations at exercise and control trials. Plasma ghrelin concentration was increased (+12.2%; $P<0.05$) and leptin concentration decreased (-20.0%; $P<0.05$) after the first 30 min of recovery at exercise trial. No differences in plasma ghrelin or leptin concentrations over time were observed during control trial. There were no relationships between basal ghrelin concentration and the measured body composition, energy balance, physical performance, or blood biochemical data. Plasma ghrelin ($r=0.75$) concentration measured immediately after the training session were related ($P<0.05$) to the distance covered, but no such relation was observed for post-exercise leptin concentration ($r=-0.16$; $P>0.05$). In conclusion, these results suggest that acute negative energy balance induced by a single prolonged endurance rowing training session elicits a metabolic response with opposite changes in ghrelin concentrations in competitive male rowers.

THE EFFECTS OF RESISTED TRAINING USING PARACHUTE ON SPRINT PERFORMANCE

SMIRNIOTOU, A., MARTINOPOULOU, K., ARGEITAKI, P., PARADISIS, G., KATSIKAS, C.
KAPODISTRIAN UNIVERSITY OF ATHENS

Introduction: Running velocity is an important element of successful performance in many sports. Two important factors that affect running velocity are stride length and stride frequency (Mero et al, 1992). Research has shown that running velocity is improved using repetitive sprint training and strength training (Delecluse et al., 1995). The means utilized in sprint training with pull against resistance are sled and parachute sprinting. The purpose of this study was to examine the effects of resisted (using parachute) and un-resisted sprint training programs on acceleration and maximum speed performance.

Methods: 16 sprint athletes (12 male, 4 female), age 25±4 years, completed a resisted (n=8) and an un-resisted (n=8) sprint training program. The resisted group followed the program towing a large size chute and the un-resisted group followed a similar sprint training program without resistance. The training program consisted of 4x30m and 4x50m maximal runs and was applied 3 times/week for 4 weeks. All subjects performed a 50m run and the running velocity of 0-10m, 10-20m, 20-40m and 40-50m was measured. In addition, stride length, stride rate, contact time and flight time were evaluated between the 1-7m during the acceleration phase and between 40-47m during the maximum speed phase. A series of ANOVA was used separately for acceleration and maximum speed phases.

Results- Discussion: The resisted sprint training group improved running velocity in all sections of acceleration phase 0-10m, 10-20m and 0-20m, while un-resisted sprint training group in the run section 0-20m. Comparison between groups indicated that running velocity was significantly higher during run section 0-20m in the resisted group compared to the un-resisted group ($F1, 12=5.307$, $p=0.04$). For the maximum speed phase the resisted sprint training program improved running velocity in the 40-50m run section and the maximum running velocity between 40-47m, while un-resisted sprint training had no effect in any run section in the maximum speed phase. Stride length increased after resisted and un-resisted sprint training in acceleration phase, whereas stride rate increased only after resisted sprint training in maximum speed phase.

Resisted sprint training with a large size chute for 4 weeks significantly improves running velocity during acceleration phase by increasing stride length and during maximum speed phase by increasing stride rate in sprint athletes.

THE EFFECT OF ENDURANCE RESPIRATORY MUSCLE TRAINING ON NORMOXIC AND HYPOXIC PERFORMANCE

KERAMIDAS, M.E., DEBEVEC, T., AMON, M., KOUNALAKIS, S.N., MEKJAVIC, I.B.
JOZEF STEFAN INSTITUTE

Introduction: The evidence regarding the effect of endurance respiratory muscle training (RMT) on exercise performance remains equivocal (Wylegala et al., 2007; Sonetti et al., 2001), which may be attributed to the fact that very few studies in the past have used appropriate control or placebo groups (Sheel 2002). The present study investigated the effect of endurance RMT on normoxic and hypoxic endurance performance.

Methods: Eighteen healthy males were stratified for age and aerobic capacity; and randomly assigned to either the RMT (n=9) or control training group (CON, n=9). Both groups trained for 1-h on a cycle-ergometer 5•d•wk-1 for 4 wks at intensity corresponding to 50% of normoxic peak power output (PPO). Additionally, the RMT group performed a 30-min specific endurance training of respiratory muscles (Spirotiger®, Bologna, Italy - isocapnic hyperpnea) before cycling. Pre, mid, post and 10-d after the end of training period, subjects performed blood tests, pulmonary function tests (PFTs), VO2max test in normoxia (VO2maxNOR) and in hypoxia (VO2maxHYPO; FIO2: 0.12); and constant power test at 80% of pre-training VO2maxNOR in normoxia (CPTNOR) and in hypoxia (CPTHYPO; FIO2: 0.12).

Results: Both groups enhanced VO2maxNOR, but only the RMT group improved ($p<0.05$) VO2maxHYPO post training. Furthermore, only the CON group increased PPO, whereas the RMT group had higher values of minute ventilation at the same relative intensity. Both groups increased CPTNOR, but only RMT maintained the adaptation 10-d after training. CPTHYPO remained unchanged in both groups.

Discussion: Endurance respiratory muscle training appears to enhance hypoxic aerobic capacity without a concomitant enhancement of hypoxic exercise endurance performance. In summary, RMT does not benefice performance under normoxic conditions.

PP-NU01 Nutrition 1

NUTRITIONAL ERGOGENIC AIDS USAGE AND NUTRITIONAL KNOWLEDGE IN ELITE FEMALE VOLEYBALL PLAYERS

KARABUDAK, E., KIN-ISLER, A.

BASKENT UN

Introduction: Recently, an increasing use of nutritional ergogenic aids has been observed in various sports, particularly among elite athletes (Ronsen, et al., 1999). Without much scientific backing, a host of dietary supplements have lately been introduced to fill the proposed "micronutrient gap" between the daily requirements and the actual dietary intake, targeting both the general population and specific athletic groups (Rosenbloom et al.,2002). Therefore, the aim of this study was to examine nutritional ergogenic aids usage and nutritional knowledge among elite female volleyball players.

Methods: Sixty seven volunteer elite female volleyball players, age 15-33 (mean 23.1 ±3.96 years) were included in this study. The instrument was a questionnaire designed to assess nutritional knowledge of athletes. We developed the instrument using selected questions from questionnaires created by Zawila et al (2003). Thus, the entire questionnaire contained 78 questions and was scored in a true/false manner. The questionnaire content consisted of the following: hydration status, macronutrients, vitamins and minerals food variety and groups, relation to food and health, nutrition training, body composition. Athletes were given another questionnaire including question about use of nutritional ergogenic aids. For 2-group comparisons, independent t test were used to identify evidence of a significant difference.

Results: Use of supplements was widespread with 56.7 % of volleyball players declaring supplement use. None of the volleyball players gave correct responses to the whole total nutrition knowledge (38-60 point, min-max) and subgroups questions except for hydration questions. The mean total nutrition knowledge score of athletes who usage supplement and who don't usage supplement were 51.5 ±5.47 and 50.5±4.84 points, respectively (mean ± SD). No significant difference was observed between the mean total nutrition knowledge score and their subgroups score of both groups.

Discussion: Although the results of this study reflect the knowledge of elite female volleyball players and cannot be generalized to all athletes, they indicate that nutritional knowledge may not have an effect on athletes supplement usage. Athletes are exposed to nutrition information from multiple sources, and dietetics professionals are in a position to provide accurate and timely information on a variety of topics of interest to athletes (Ronsen, et al., 1999). Results from this survey suggest that athletes could benefit from learning how supplements affect performance and should be cautioned that supplements cannot make up for a poor-quality diet.

THE EFFECT OF NUTRITION EDUCATION INTERVENTION ON DIETARY INTAKE AND NUTRITIONAL KNOWLEDGE IN ADOLESCENT ATHLETES

KARABUDAK, E., KAYALI, F.

BASKENT UN

Introduction: Previous studies showed that athletes have limited knowledge of nutrition and did not use their knowledge in making proper food choices (Kunkel et al., 2001). Therefore, the purpose of this study was to evaluate the efficacy of a nutrition education intervention to improve nutrition knowledge, to build self-efficacy with respect to making healthful dietary choices, and improve dietary intake in adolescent male athletes.

Methods: Adolescent male basketball players (n=10, age 10-12 yr) constituted the subjects of this study. All athletes completed the nutrition knowledge (NK) and nutrition attitude (NA) questionnaires as pre-education in order to evaluate their nutrition status. The true/false NK test included 17 items related to total calories, macro and micro nutrient, and intake of these components. A total NK scores was based on the sum of all of the correct answers, worth 1 point each. The purpose of these questionnaires was to gather the baseline data necessary for the development of an intervention. A 3-day dietary record was also administered with the pre-and post education to determine any changes in selection of pre-competitions meals, types of fluids consumed prior to and during games, and general dietary habits. The 3-day diet record was averaged and then analyzed using the computer program. Nutrition education seminars were conducted by dietitians for 2 months, 1-hour educational session conducted on a monthly basis. At post-education, athletes completed the same questionnaires. The Wilcoxon Signed Ranks Test was used to analyze the results between pre-and post nutrition education.

Results: The total possible score for the NK assessment was 17; therefore, the pre-education score was slightly below an average score (12.9). The total possible score for NA was 56. The mean pre-education score on NA making healthful choices were 46.9. After nutrition education experienced a significant increase in NK and NA (respectively, 14.3 and 52; $p<0.05$). Pre-and post education comparisons of the athletes indicate that except for monounsaturated fatty acids, sodium and bread ($p<0.05$), there was no significant improvement in dietary intake and food choices due to the limited duration of the education ($p>0.05$). After nutrition education, the amount of fluid intake was increased by 13.6% ($p>0.05$).

Discussion: Adolescent athletes in the present study demonstrated a higher level of knowledge and attitude after nutrition education. However, the knowledge and attitude did not lend itself to improvement of dietary intake. According to these results, it is believed that providing adequate and balanced nutrition training starting from childhood with regular intervals decreases the health and performance problems associated with inadequate and imbalanced nutrition (Barr, 1987; Chapman, et al. 1997).

WEEKLY VIGOROUS PHYSICAL ACTIVITY AND DIETARY HABITS IN SEDENTARY UNIVERSITY STUDENTS. GENDER-RELATED DIFFERENCES

SABLONE, A., DI BLASIO, A., D'ANGELO, E., DI DONATO, F., DI GREGORIO, S., DI RENZO, D., PANTALONE, P.P., RIPARI, P.,3
ITALY

Introduction: The finding that women seem to compensate the increased exercise-related energy expenditure, through high lipid-dense foods (Stubbs et al., 2002), suggested us to verify if this is due to the intensity of daily body movement and energy expenditure or to exercise program participation through 2 different protocols. The aim of this study was to investigate the interaction between the amount of weekly vigorous physical activity and gender on dietary habits of sedentary university students.

Methods : We recruited 30 sedentary university students among courses with mandatory attendance. 15 were women (22.07±2.46 yrs; %fat mass 29.63±7.79) and 15 men (23±3.5 yrs; %fat mass 22.30±5.47). Nobody had gone on a diet during the last 2 years and did not take part in exercise programs during the last year. Physical activity was investigated by International Physical Activity Questionnaire (IPAQ). Qualitative and quantitative characteristics of daily meals were assessed by a dietician with 3-day dietary records, by WinFood-due software (Medimatica, I). Body composition was estimated by single-frequency electrical bioimpedance (Akern, I). We created 2 sub-samples according to the 50th percentile of weekly min of vigorous physical activity: LOW (<30 min) and HIGH (>30 min). M-ANOVA was performed taking gender and groups of vigorous physical activity as independent variable, while parameters of dietary habits were taken as dependent variables.

Results: Groups differed only in vigorous physical activity. Men had worse values than women of both daily intake of percentage of lipids ($F(1, 27)=5.669$; $p=0.027$) and carbohydrates ($F(1, 27)=4.031$; $p=0.05$) and that of satured fat ($F(1, 27)=4.549$; $p=0.04$). The interaction between gender and weekly min of vigorous physical activity showed that men and women differed in lipid ($F(1, 27)=3.771$; $p=0.05$) and satured fat intake ($F(1, 27)=6.903$; $p=0.016$) trend. Men showed a worse tendency than women.

Discussion: Our results show that, if sedentary women have a correct distribution of daily energy intake among macronutrients, independently from weekly min of vigorous physical activity, both lipid and satured fat intake of sedentary men are linked with weekly min of vigorous physical activity. In fact, more active men had high lipidic diet. Weekly amount of vigorous physical activity seems to be negatively linked with a healthy diet in men but not in women.

CARBOHYDRATE INGESTION IMPACTS ON MALE TRAP SHOOTING PERFORMANCE

BRAAKHUIS, A., HARDEN, D., NOTTLE, C.
WAIKATO INSTITUTE OF TECHNOLOGY

Researchers have demonstrated that consumption of a carbohydrate solution during prolonged exercise enhances performance, but the effect of these supplements on shooting sports is unclear. The aim of this study was to determine the effect of a carbohydrate solution on performance in the sport of Olympic Trap shooting. In a double-blind, balanced, crossover design, eight fasted Olympic Trap shooters (mean ± SD: age 33.0 ± 15.9, weight 91.9 ± 21.7 kg) were required to ingest a liquid form of glucose or similarly flavoured placebo throughout a simulated shooting performance, following an overnight fast. Glucose content was 7.6% in a total volume of 1300 millilitres, with 100 millilitres being consumed every 10 minutes. Blood glucose levels were tested every 15 minutes. Each shooter completed three rounds of 25 targets, 20 minutes apart in one testing session. Changes between conditions for the same time interval, and for performance and blood glucose levels across time intervals were analysed. No significant blood glucose changes ($p>.05$) were seen in the placebo group. Blood glucose results were elevated from fasting levels and were significant in the final round ($p<.05$). No significant changes in performance were seen between the two drink groups (glucose score (mean ± SD) 56 ± 5; placebo score 54 ± 7). Prior to commencing the study all shooters completed a baseline shooting score under non-fasted conditions. The performance scores for shooters whilst consuming both drinks were only ever reduced from baseline (baseline score 61 ± 7), hence average scores across the time intervals never exceeded their average baseline performance. Despite no statistical change in performance it is shown that limiting your glucose intake negatively affects scoring consistency represented by first barrel, second barrel and lost targets. Whether this is indicative of cognitive performance would require further research.

NUTRITION KNOWLEDGE AND DIETARY HABITS OF ATHLETES

OBROVAC, M., COLIĆ BARIĆ, I., MATKOVIĆ, BR.
FACULTY OF FOOD TECHNOLOGY AND BIOTECHNOLOGY, 1FACULTY OF KINESIOLOGY UNIVERSITY OF ZAGREB

Introduction: The nutrition of athletes has been of interest to scientists for decades and since the origins of sports competitions the questions about what to eat and what to drink in order to improve performance have been raised. Today there are scientific proofs that an adequate dietary habits influences in a large extent to an athlete's health, body composition, and energetic pathways during the activity as well as during the competition or recovery. Athletes should be well informed about the food groups, caloric intake, and daily meal schedule.

The aim of this study was to evaluate nutrition knowledge and dietary habits of athletes and to estimate inter-relationship between them such as the differences between male and female. The source of nutrition information and food supplements related behaviours were also taken into consideration.

Methods: Respondents of this study were active and succesful athletes (n=100) both genders. Methods used in this study were for this occasion specially designed questionnaire for nutrition knowledge determination, and dietary assessment method through qualitative food frequency questionnaire (FFQ).

Reasults and Discussion: Results showed middle knowledge level of nutrition which statistically wasn't significantly affected by the frequency of asking for nutrition information and qualification level of the nutrition information source. Respectively high number of respondents were estimated for irregular meal consumption, especially snack meals and they in average don't satisfy the recommendations for optimal hydration. The knowledge level of nutriton doesn't significantly influence on the quality of dietary habits among respondent ath-

letes. Estimated knowledge level of nutrition and dieatary habits don't differ between genders. Still, statistically significant positive correlation between knowledge level of nutrition and quality of dietary habits is estimated among male althletes and all questioned athletes but not between female athletes. The recommendations are to improve conscionsness about the importance of well balanced diet for athletes, and to educate them as well as their coaches.

NUTRITIONAL INTERVENTION IN TRACK AND FIELD ATHLETES

SILLERO QUINTANA, M., GARCÍA APARICIO, A., TORRES GARCÍA, A., GARRIDO PASTOR, G.

FACULTAD CIENCIAS DE LA ACTIVIDAD FÍSICA Y DEL DEPORTE - INEF (UPM, MADRID). INSTITUTO DE CIENCIAS DEL DEPORTE (UCJC, MADRID).

Introduction: Optimal nutrition contributes to achieve maximum athletic performance. Track and field events include the development of different motor skills: race walking, running, jumping, and throwing. The aim of this work is to compare nutritional patterns in athletes competing in different events, and verify possible changes in dietary practices after intervention.

Methods: Diet composition was analysed in 44 Spanish elite athletes [26 female (F) and 18 male (M)] competing in three different events: fast events (FE) include jumpers, throwers, and multi-event (n = 12; Age =22.5 ± 4.8; BMI = 22.4 ± 3.9), middle distance (MD) runners (n = 17; Age =24.7 ± 4.0; BMI = 20.0 ± 1.5) and long distance (LD) runners (n = 15; Age =24.9 ± 4.9; BMI = 19.4 ± 1.1), to describe and compare their usual nutritional patterns. After a preliminary diet evaluation, an individual nutritional report was given and a personal advice program was performed to all of them focusing on improving their diet quality. To verify possible changes after this intervention, a new diet composition evaluation was done (160 ± 88 days after) in 27 of them (8 FE, 11 MD and 9 LD).

Diet composition was estimated by retrospective method for a 3 day period (rest, moderate, and intense training days); additionally, they completed a 24h activity questionnaire to estimate energy requirements (EER) (IOM, 2002) during the same 3 day period.

Results: Comparing data between the three groups (FE, MD and LD): energy intake (EI) and energy distribution (%P, %CH, %L) were similar despite a tendency to a higher %CH and a lower %L in the LD group (FE = EI: 2653± 950, %P: 19, %CH: 46, %L: 35%; MD = EI: 2668 ± 676, P: 17%, ,CH: 45%, L: 35%; LD = EI: 2737 ± 518, P: 16%, ,CH: 51%, L: 32%). EER were similar to IE in the three groups. Attending to gender, absolute values for EI (Kcal/day), P, L and CH (g/day) were significantly lower in females, but these same values, expressed in terms of body weight, were similar in both genders.

After intervention, the EER was lower (2516 ± 480 vs 2816 ± 461 kcal/d), and so was the EI ($p<0.005$) expressed in absolute values (2466 ± 546 vs 2781 ± 763 kcal/d) and relative to body weight (45 ± 12 vs 40 ± 10 Kcal/Kg/d). Elite athletes were able to get an energy balance in both trials. After intervention, CH expressed as % of the total EI was significantly higher (51 ± 8 vs 47 ± 6) (p≤0.01), conversely a decreased L intake, expressed as % of the total EI (31 ± 6 vs 36 ± 5), and a significant (p≤0.0001) decreased L (saturated and monounsaturated) intake (g/d) were found.

Discussion/Conclusion

CH intake was still lower than recommended for athletes (Burke, 2007). Other nutritional intervention, such as a personal and close relationship with athletes and their coaches, is needed in order to improve further their diet energy distribution.

THE RELATION BETWEEN SECRETORY IGA CONCENTRATION IN SALIVA AND FOOD INTAKE IN JAPANESE YOUNG MEN

TOKUNO, Y., KISHI, Y., EDAMATSU, M., IWAI, M., TAKAHASHI, Y., UNOKI, K., NAGASAWA, N., IKEGAWA, S., TSUNODA, N., KURISAKI, J.

1. JUMONJI UNIVERSITY, 2. KOKUSHIKAN UNIVERSITY

Introduction: Recently, it is reported secretory immunoglobulin A in saliva (s-IgA) can be a useful stress maker because s-IgA plays an important role in the defense mechanism of mucosal membranes for resistance to infectious disease. And it is thought that saliva production is greatly influenced by state in mouth and diversified eating habits. Therefore to search for the possibility of making use of s-IgA concentration for health indicator, we investigated the relation between s-IgA concentration and food intake in Japanese young men who belong to baseball team.

Methods: The subjects were 39 Japanese young men (aged 18-21) who belong to baseball team. Saliva samples were collected chewing for one minute after the meal in one hour or more. The s-IgA was examined by ELISA (Enzyme-linked immuno-sorbent Assay) using anti-human IgA and protein in saliva was determined by BCA method. We investigated food intake by food frequencies questionnaire and lifestyles.

Results: The numbers of regular people were 13 in the team and the rest were the substitute. In the physical characteristics of subjects, Height was 173±4.3cm, Weight was 70±6.4kg, Body Mass Index(BMI) was 23.4±1.7kg/m2. There was no difference between regular persons and substitute persons in the body mass characteristics. The average s-IgA concentration was 43.1±36.5 μg/mL. The average s-IgA concentration of the regular persons was lower than that of the substitute. The average of food energy was 2842±931 kcal. The average of food energy was also lower than that of the substitute.

Discussion: These subjects were baseball players therefore they have to make more meal than the person who doesn't exercise. But most of them didn't cover estimated energy requirement: EER. According to Bruins GJ, they reported that physical exertion, such as practicing sports, might have an influence on the secretion and composition of saliva. After a single physical exertion, the alterations are reversible and the values return to baseline within a few hours. In the case of long lasting intensive physical exertions, for instance lasting several months, particularly the decrease in s-IgA concentration seems to have a more permanent character. And Sakamoto reported that the s-IgA level was significantly increased in the pre-germinated brown rice diet group. They have shown that pre-germinated brown rice may have beneficial effects on psychosomatic health. In this research, the s-IgA concentration of the subjects who had felt the

mental stress tended to be low. Therefore for these baseball players, s-IgA concentration is thought to be useful to judge both physical and psychological conditions.

In handball a victory can be determined in details such as a powerful and agile team (1). For this an adequate diet plan is essential, it can assure the energy required to the last counter-attack. Define individual characteristics is crucial to recognize what can be improved. Purpose: the aim of the present study was to analyze body and diet composition of handball players and compare these variables to the international recommendations for macro and micronutrients. Methods: The sample was constituted by 20 handball male athletes (14 to 17 years old). Body composition was determined by body mass index - BMI (kg/m2), skinfolds (mm) and body fat percentage was calculated according to Slaughter (2). Food consumption (macronutrients and micronutrients) was obtained by 24-hour recall and calculated by nutritional Dietwin® software. Results: Athletes presented average age of 14,9 ± 1 years old. Mean body composition: 18,5 ± 4,3% of body fat; 173,9 ± 7,1 cm of stature; 65,5 ± 9,3 kg of body mass and 21,60 ± 2,00 kg/m2 of BMI. According to the 24-hour recall, athletes nutrient intake was: 2.293,5 ± 644,4 kcal; 1.238,3 ±439,5 kcal of carbohydrates (53,4 ± 6,3 %); 437,6 ± 143,2 kcal of protein (19,2 ± 4,2 %); 617,5 ± 177,8 kcal of fat (27,4 ± 5,0 %); 753,3 ± 336,8 mg of calcium; 2918,4 ± 1253,6 mg of sodium; 17,2 ± 7,0 mg of iron and 13,4 ± 7,4 g of dietary fiber. Discussion and Conclusion: According to Dietary Reference Intake (DRI) (3) the athletes showed an appropriate macronutrient intake. However handball athletes need a high glycogen content which means that they must have a hyperglicidic diet. Micronutrient analysis showed that sodium and calcium ingestion were the major problem. Sodium reached toxic levels and calcium intake was almost half of the recommendation. Those data showed us that a nutritional intervention is vital in order to improve performance and prevent any future health problem.

THE STUDY OF PREVALENCE ERGOGENIC DRUGS USE,THEIR ATTITUDES BY BODYBUILDERS IN SARI CLUPS

FARZANEGI, P., EBRAHIMPOUR, Z., HABIBIAN, M.

ISLAMIC AZAD UNIVERSITY

The study of prevalence ergogenic drugs use,their attitudes by bodybuilders in sari clups

Abstract

Introduction: Dietary supplements and ergogenic agents, including anabolic steroids, are common components of present-day bodybuilder and weightlifter training regimens. Prior reports of anabolic steroid use suggest polypharmacy and high doses of injectable agents(Perry et al.,2005). The purpose of this study was to determine the prevalence of ergogenic drugs,their attitude to ward these substance and their side effect of bodybuilders in sari clubs .

METHODS: The quesnnairs were distributed among 100 bodybuilders(age 25/6+6years,weighe87/17+16kg ,high 175/88+7 cm).The data collected were analyzed usingpoint-biserial correlation coefficients,phi correlation and contingency correlation.

RESULTS: The results showed that the majority of bodybuilder believed that ergogenic drugs caused better physical appearance,take champion rank and health body(31/42%,16/73%,15/92%). Then 64 (%64) from 100 samples of this study have taken these ergogenic substance at least once. Also, the average of prevalence's total score of these substances was 9.5 (MAX=45), the average score of awareness of their side effects 60 (MAX=100), and the average score of knowledge ergogenic substance 25.11(MAX=50).

The analyzing of information indicated that the prevalence of ergogenici substance has a completely significant relation with job, the record of body building, the record of championship, the championship field, the championship level, the amount of awareness about side effects of this ergogenic substance and knowing them($p<0.05$). But it hasn't any significant relation with education level, and the clubs & provinces distribution ($p>0.05$).

Discussion: The number of athletes self-administering ergogenic pharmacological agents to increase their competitive edge continues to be a problem. Most athletes using anabolic steroids (AS) have acquired a crude pharmacological database regarding these drugs(Kutscher et al.,2002). The principal reason bodybuilders used steroids was related to their perception that these drugs were an important factor in winning competitions. Another important motivating factor for use was consistent with reports that significant gains in strength could be achieved by including anabolic steroids as part of the training regimen in spite of the reported adverse side-effects(Tricker et al.,1989, standard., 2004).This conclusions suggests that bodybuilders and coach need more information.

CONCLUSIONS OF HUNGARIAN ELITE ATHLETES' DOPING CONTROLS IN THE YEAR OF THE OLYMPIC GAMES IN BEIJING.

TROMBITÁSNÉ RÁNKY, M., NOE, J., FRENKL, R.
SEMMELWIES UNIVERSITY, UNIVERSITY OF PANNONIA VESZPRÉM

Introduction: The sportsmen have been used different medicines and dietary supplements during the trainings and competitions. Theirs quantity and quality are disputable by point of view of health protection many times. According to our opinion it is necessary systematic health education and scientific nutrition advices to fend off pressure of consuming supplements induced by the commercial advertisements and by psychological reasons. Sport background of these acting we should like help on with special data bases. In former researches we fixed information during long time (7 years) one kind of sport (athletic). In the present case, our aim gain data about medicine and supplement consumption habit and specification of Hungarian elite athletes of different discipline of sport during one Olympic year.

Methods: The analyzed information based on the admissions of Doping Control Collection Form of different Hungarian elite athletes in Hungary in time from January 01 2008 to December 31 2008. The Forms are recording the names of medicines and nutrition supplements consumed by the competitors ten days prior the control. We have created a database out of these data.

Results: The members of examination were representatives of 32 Olympic-, 12 Paralympics- and 5 non Olympic -disciplines.

The total sum of Doping controls was 1518 (n= 851m, n=667w) out during in the given period of time.

The competitors of Olympic disciplines have been participated 1396 in case n=766m (503 urine samples, 263 blood samples), n=630w (422 urine s, 208 blood s).

Non Olympic sportsmen were checking 61 in case, n=43m (41 urine s, 2 blood s), n=18w (17 urine s, 1 blood s).

Paralympics had controls 61 in case, n=42m, n=19w all in urine.

In the period of survey only in case 70 (4.6%) hasn't use any medicines and dietary supplements.

Use of the prohibited medications with license were detected 97 (6.38%) in case. (n=50m, n=47w)

Numbers of articles named by Hungarian elite athletes were investigated grouped to medicines and nutrition supplements by the athlete gender and disciplines of sports.

Conclusions: It has been discovered from Doping Collecting Forms too many sports men use different non steroid medicines and pain relieves with together.

After detailed analyzing of consumption of vitamins, the results showed too many competitors used by more types of vitamin complex.

In our opinion there is a high rate of consumption if somebody used five or more dietary supplements in the checking period. We was detected 66 in case (n=49m and n=17w) when the number of taken supplements are over then 10.

Conclusions of our examination that significant numbers of sportsmen do not used the supplements according to needs.

For optimization of nutrition advices should be a theoretically accept for sports, like the standards RDA, ODI, PDI.

PHYSICAL ACTIVITY AND EXERCISE-INDUCED LYMPHOCYTE APOPTOSIS

ENSENYAT, A., SAGARRA, L., PORTERO, M., PAMPLONA, R.
UNIVERSITY OF LLEIDA

Introduction: A decrease in lymphocyte counts and changes in its composition has been described after prolonged and sustained vigorous exercise. To evaluate the contribution of apoptosis to lymphopenia during early recovery from acute physical exercise in humans, a systematic review has been carried out.

Methods: From January 1998 to August 2008, 11 studies investigating the incidence of apoptosis in human blood lymphocytes during early recovery from an acute exercise bout have been published. They comprise of 17 effects from a total sample of 90 volunteers. Exercise mode differed greatly among studies and included; short duration (<60') moderate intensity (60%VO2max) exercise; short duration high (>70%VO2max) intensity exercise; prolonged (>120') exercise; eccentric exercise and progressive maximal exercise. In all cases, venous blood samples were collected before and early after the exercise bout. In some studies, a third sample time-point was allocated at some time between 1 hour to 24h of recovery.

Lymphocyte apoptosis was analyzed by cytometric procedures or by optic microscopy determination of apoptotic morphological changes.

Results and Discussion: Results show that an intensity threshold can exist as exertion below 60%VO2max did not induce significant changes in apoptosis parameters such as annexin-V or CD95 expression, or caspasses activities in lymphocytes. On the other hand, increases in percentages of lymphocytes expressing annexin-V or CD95, or in caspasse 8 and 9 activity (Mooren, 2002; Tuan, 2008; Wang, 2005) have been reported immediately after intense exercise. Sixty minutes after exertion values had returned to resting levels, except for the percentage of NK cells expressing CD95 that were still elevated (Simpson, 2007), and for caspasse 3 activity that increased at 24 hours of recovery (Wang, 2005).

A duration threshold can also exist seeing that percentages of annexin-V or CD95 lymphocytes were superior after long duration running; and persisted elevated for a longer time; than after short duration running at a similar speed (Mooren, 2004; Steensberg, 2002).

Navalta (2005) notes an increase in percentage of lymphocytes with morphological signs of apoptosis immediately after a progressive and maximal exercise test that returned to resting levels in the first hour of recovery.

Physical fitness can also regulate apoptosis, as 180' after a marathon run, the percentage of lymphocytes expressing annexin-V was significantly elevated from pre-exercise values in bad-trained athletes while in well-trained athletes there was no increase (Mooren, 2004). The percentage of lymphocytes expressing CD95 increased but did not differ among groups.

PGC1A GENE VARIATION AND PHYSICAL PERFORMANCE IN LITHUANIAN ATHLETES

GINEVICIENE, V., KUCINSKAS, V.
VILNIUS UNIVERSITY

INTRODUKTION Peroxisome proliferator-activated receptor gamma coactivator-1a (PGC1A) is a transcriptional coactivator with crucial impact on multiple aspects of cellular energy metabolism including mitochondrial biogenesis and cellular respiration, the regulation of adaptive thermogenesis, adipocyte cell development and also lipid and glucose metabolism. The most common coding single nucleotide polymorphism - G1444A (rs8192678) is located in exon eight and cause amino acid substitution Gly482Ser. PGC1A [A] allele is associated with traits of the metabolic syndrome.

METHOD We tested the hypothesis that the frequency of the minor [A] allele at the PGC1A locus is lower in Lithuanian professional athletes (cases) [N=551; mean age: 17.7±5.3 yr], than in controls [N=97; mean age: 31.3±13.5 yr]. Athletes represented 4 functional groups: endurance (N=64); mixed sports (N=33); strength and speed (N=47), and team sports (N=407). Their physical characteristics were (mean ± SD): height 176±10.4 cm, weight 68.8±15.6 kg, body mass index 21.9±3.4 kg/m2, body muscle mass 36.7±9.5 kg and body fat mass 8±3.2 kg, muscle/fat mass index 5±1.6. All subjects gave informed consent before participating and went through a medical examination. Genomic DNA was extracted from peripheral blood leukocytes. Genotyping for PGC1A [G/A] polymorphism was performed by PCR and restriction enzyme digestion. All the statistical analyses were carried out by use of the SPSS program version 13. Allele frequencies were compared between athletes and controls.

RESULT Genotypes of athletes were identified as [G/G] 52.1%, [G/A] 42.1% and [A/A] 5.8% (χ2=2.83, p=0.09) and the genotypes in the population samples were [G/G] 42.2%, [G/A] 37.8% and [A/A] 20.0% (χ2=3.79, p=0.055). The frequency of the minor [A] allele was significantly lower in athletes than in controls (26.9% vs. 38.9%; P = 0.01). In the mixed sports group the frequency of the [A] allele was less common than in other sports groups: in the endurance group and the strength and speed group the frequency of the [A] allele was 26.6%, and in the team sports group the frequency of this allele was 27.4%.

DISCUSSION PGC1A [A/A] genotype is less frequent in all Lithuanian athlete groups in comparison to the general population (5.8% vs. 20.0%; P=0.005). The results of the present study imply that the PGC1A [G] allele of the [G/G] genotype is more common in the professional athlete group than in the general population of Lithuania. In conclusion, the present findings suggest that there is an association between PGC1A G1444A polymorphim and physical performance in Lithuanian athletes.

HIGH MOLECULAR MASS PROTEOMICAL EVALUATION OF CARDIAC MUSCLE OF RATS SUBMITTED TO AEROBIC EXERCISE.

ROCHA, L., PETRIZ, B., BORGES, D., OLIVEIRA, R., ANDRADE, R., PEREIRA, R., FRANCO, O.
UNIVERSIDADE CATOLICA DE BRASILIA

Several reports describe regular exercise as an important factor for health improvement. This practice could be directly related to con tractile force development in cardiac cells. In order to evaluate the relations between exercise intensity protein and mRNA expression, 30 isogenics adult male rats Wistar (Rattus norvergicus) were randomly divided into four groups and further submitted to swimming training during twelve weeks with 2.5% (TG1); 5.0% (TG2) and 7.5% (TG3) overload and one control group (CG) by using sedentary rats. Firstly, our findings demonstrated clear morphologic alterations, suggesting that the intrinsic contractile characteristics of myofibrils could be modified in order to contribute for an increase of left ventricle activity. Furthermore, reliable differences at high molecular mass 80 to 240(kDa) protein maps were observed, by using one and two dimensional electrophoresis .Major proteins were further indentified by MALDI ToF-ToF. Among these proteins, all treatments demonstrated an increased expression of protein and mRNA of myosin heavy chain in comparison to CG. Moreover the improvement of other proteins were also observed as troponin, sarcomeric proteins, proteins associated to oxidative metabolism as oxidoredutases, translocases of mitochondrial membrane and proteins analogous to super oxide desmutases. These modifications in protein expression patterns suggest a clear correlation to standard intensity obtained in each training group. One of these effects demonstrated in high intensity when compared to low and moderate, showed to be more efficient in the MHC enhancing expression in cardiac contractile cells. These alterations seem to demonstrate that exercises of moderate and high intensity can induce significant molecular and structural alterations in the cardiac contractile cells

EFFECTS OF DIFFERENT INTENSITY AND DURATION OF ENDURANCE TRAINING ON SATELLITE CELL CONTENT IN RAT SKELETAL MUSCLE

KUROSAKA, M., NAITO, H., ICHINOSEKI-SEKINE, N., OGURA, Y., KAKIGI, R., KATAMOTO, S.
JUNTENDO UNIVERSITY

Introduction: Skeletal muscle satellite cells play an important role for muscle fiber regeneration and hypertrophy. It is well known that resistance training can increase the number of satellite cells with muscle hypertrophy. Recently, it has been reported that relatively high intensity endurance training causes proliferation of satellite cells in human skeletal muscle with hypertrophy. Also, we clarified that relative low intensity and long duration endurance training by using voluntary wheel running induced the number of satellite cells in rat plantaris muscle without hypertrophy. Therefore, not only exercise intensity but also duration might affect for an increase in satellite cell

content. However, it is not clear which factor is important to increase satellite cell content. Therefore, this study investigated the effects of difference in intensity and duration of endurance training on satellite cell content in rat plantaris muscle.

Methods: Forty-one 17-week-old female Sprague Dawely rats were assigned to one of four groups: control (CON: n=8), high intensity and high duration (H90: n=7), high intensity and low duration (H30: n=8), low intensity and high duration (L90: n=9) and low intensity and low duration (L30: n=9) group. Exercise intensities were controlled by running speed and grade (High: 25-30m / min · 0-18%, Low: 25-30m / min · 0-3%). Exercise durations were 90 and 30min for high and low duration, respectively. Training groups exercised 5 days / week on a motor driven treadmill for 10 weeks. After the training period, the plantaris muscle was removed under anesthesia, weighted and frozen with liquid nitrogen. Serial transverse sections (7μm thick) were made using a microtome at -20°C. Satellite cells were immunohistochemically stained, visualized and identified by using anti-Pax7 and anti-laminin antibody and DAPI. The number of muscle fibers, mean fiber area, myonuclei and satellite cells were measured. To determine mean fiber area for each fiber types, mATPase staining was performed.

Results: Endurance training increased percentage of satellite cells (CON: 1.42 ± 0.35%, L30: 1.56 ± 0.30%, L90: 1.73 ± 0.34%, H30: 2.21 ± 0.31%, H90: 2.49 ± 0.29%), however, there were no significant differences in muscle weight, mean muscle fiber area and myonuclei per muscle fiber between groups. The percentage of satellite cells was no significant difference between H30 and H90, but there was significantly higher in both H30 and H90 groups compared with L30, L90 and CON group ($P < 0.05$).

Conclusion

It was concluded that intensity of the endurance training affect an increase in number of satellite cells in the rat plantaris muscle.

EXERCISE TRAINING IMPROVES AGING-INDUCED DECREASE OF PPAR-ALPHA AND PGC-1ALPHA PROTEIN LEVELS IN CARDIAC AND SKELETAL MUSCLES

IEMITSU, M., MAEDA, S.

INTERNATIONAL PACIFIC UNIVERSITY

Background and Purpose: Exercise training improves aging-induced decrease of oxidative metabolic capacity in mitochondria of cardiac and skeletal muscle1. However, the mechanisms underlying improving oxidative metabolic capacity in the cardiac and skeletal muscles by exercise training are unclear. Peroxisome proliferator-activated receptor (PPAR)-alpha regulates 3-hydroxyacyl CoA dehydrogenase (HSD) gene expression via PPRE transcriptional activation. Peroxisome proliferator-activated receptor gamma coactivator-1alpha (PGC-1alpha) regulates cytochrome oxidase (COX) gene expression via transcriptional activation of nuclear respiratory factor-1 (NRF-1). We investigated whether aging-induced alteration in PPAR-alpha and PGC-1alpha protein levels and these signals in cardiac and skeletal muscle is improved by exercise training.

Methods: We used cardiac and epitrochlearis muscles of sedentary young rat (4-month old), sedentary aged rat (23-month old), and swim-trained aged rat (23-month old, swimming training for 8-week, 5days/wk, 90min/day). PPAR-alpha and PGC-1alpha protein expressions were detected by immunoblot analysis. For determination of HSD, NRF-1 and COX mRNA, reverse transcription-polymerase chain reaction (RT-PCR) was used. Furthermore, enzyme activities of HSD and COX were measured.

Result: The activity of HSD and COX, which are key enzymes of energy metabolic capacity, in cardiac and epitrochlearis muscles were significantly lower in the sedentary aged rats compared with the sedentary young rats, and were higher in the trained-aged rats than the sedentary-aged rats. PPAR-alpha and PGC-1alpha protein levels in cardiac and epitrochlearis muscles were significantly lower in the sedentary aged rats than the sedentary young rats, and were higher in the trained-aged rats than the sedentary-aged rats. Additionally, in the heart, activity of PPRE DNA binding to the transcriptional regulating region and mRNA expression of HSD altered in association with changes of the PPAR-alpha protein levels. Moreover, the mRNA expression of NRF-1, activity of NRF DNA binding to the transcriptional regulating region and mRNA expression of COX altered in association with changes of the PGC-1alpha protein levels.

Conclusion: These findings suggest that exercise training may improve aging-induced impairment of metabolic enzyme activity associated with PPAR-alpha and PGC-1alpha proteins in cardiac and skeletal muscles.

SIRTUIN ACTIVATOR INCREASES ENDURANCE FOR RATS ARTIFICIALLY SELECTED TO HIGH RUNNING CAPACITY

HART, N., SARGA, L., KOLTAI, E., BRITTON, S., KOCH, L., LAMBERT, P., RADAK, Z.

SEMMELWEIS UNIVERSITY

Sirtuins are NAD+ dependent protein deacetylases and suggested regulators of aging, fat and sugar metabolisms, DNA repair, mitochondrial biogenesis and fiber type differentiation of skeletal muscle. SIRT activators like caloric restriction or supplementation of resveratrol have been shown to increase mean life span via alteration of central cellular processes. In the present study we trained selectively bred 24 generations for intrinsic aerobic high running capacity (HCR) or low running capacity (LCR) rats and some groups were supplemented by SIRT activator for 4 month. Twelve weeks exercise training significantly increased the VO2max in both groups, and the increase was almost twice as large in the LCR (26%) rats than at HCR (15%). The supplementation of SIRT stimulator (SRT501) significantly enhanced the VO2max and the running distant at HCR rats, while no significant effects were observed at LCR rats. SIRT stimulator also improved the performance at gripping. The biochemical analysis of gastrocnemius muscle revealed that both exercise training and SIRT stimulator effected the activity of SIRT1 at the nuclear extracts, moreover it appears that the NAD biosythetic activity also altered by exercise training. Our data suggest that SIRT stimulator selectively effected HCR rats and resulted in significant improvement of aerobic endurance capacity.

LYMPHOCYTE NUCLEAR DNA DAMAGE IN HUMANS: AGE AND AEROBIC CAPACITY RELATION

LYMPHOCYTE NUCLEAR DNA DAMAGE IN HUMANS: AGE AND AEROBIC CAPACITY RELATION

SOARES, JORGE1, MOTA, MARIA PAULA1, GAIVÃO, ISABEL1
1Sports Science Department, University of Trás-os-Montes e Alto Douro, Vila Real – PORTUGAL, jotafps@gmail.com
Introduction: The aging is characterized by a progressive decrease of the organic functions. However an important role has been recognized for regular exercise in improving the overall functionality of the body promoting the general health of individuals. The present aims to: 1) study the association between VO2max and age; 2) evaluate the existing association between DNA damage and oxidative damage in lymphocytes and age; 3) evaluate the association between DNA damage and oxidative damage in lymphocytes and VO2max.
Methods: To achieve this, it was gathered a sample of 37 healthy individuals, non-smokers, male, with an average age of 50.5±16.6 years old, average height of 169.68±8.44cm, average weight of 74.01±9.24kg and a average VO2max of 41.95 ± 10.72 mL/kg/min. The cardiorespiratory fitness was evaluated through the completion of the protocol of Bruce with direct measurement of oxygen consumption. For evaluation of DNA damage and oxidative DNA damage in lymphocytes, it was used the method of comet assay (comet assay - single cell gel electrophoresis) (Collins, 2004).
Results / Discussion: Results showed an inverse correlation between age and VO2max (r = -.734; p = .000), positive with DNA damage in lymphocytes and positive with oxidative DNA damage in lymphocytes, as well (r = .694; p = .000; r = .646; p = .000, respectively). Regarding VO2max, this variable is also correlated with the DNA damage in lymphocytes and oxidative DNA damage in lymphocytes (r = -.590; p = .000; r = -.453; p = .000, respectively). In short, the results of this study show that older individuals have higher DNA damage in lymphocytes compared to younger individuals, and that these higher levels are associated with lower levels of VO2máx.

EFFECT OF ADVENTURE RACE IN LEUKOCYTES DEATH

LEVADA-PIRES, A.C., FONSECA, C.E.R., BREDARIOL, F., HATANAKA, E., LOUREIRO, T.A., CURI, R., PITHON-CURI, T.C.
1. UNIVERSITY OF SÃO PAULO, 2. CRUZEIRO DO SUL UNIVERSITY, SÃO PAULO, SÃO PAULO, BRAZIL

PURPOSE: The effect of an adventure race (Ecomotion Pró), which lasted for 4-5 days, on neutrophils and lymphocytes death from elite athletes was investigated. METHODS: Blood was collected from ten athletes under rest and after an adventure race. The follows parameters of cell death were investigated in neutrophils and lymphocytes: cell membrane integrity, DNA fragmentation, mitochondrial transmembrane depolarization and ROS production. RESULTS: The adventure race decreased membrane integrity by 3 and 15% in lymphocytes and neutrophils, respectively, as compared to the rest and after the competition. The DNA fragmentation and mitochondrial transmembrane depolarization were increased in lymphocytes by 2.9- and 1.5-fold, respectively; however, these parameters do not alter in neutrophils. The ROS production was unchanged in lymphocytes from athletes as compared to the rest and after the competition, whereas in neutrophlis there was increased by 2.2-fold. CONCLUSION: Adventure race induced neutrophil death by necrosis as indicated by loss membrane integrity and induced lymphocyte death by apoptosis as indicated by increased DNA fragmentation and mitochondrial transmembrane depolarization. ROS production by cells might be involved in cell type death. FINANCIAL SUPPORT: Fapesp, CNPq and CAPES.

THE EFFECTS OF MORTON'S FOOT ON STATIC-DYNAMIC BALANCE AND VERTICAL JUMP PERFORMANCE OF MODERN DANCERS

AGOPYAN, A., ERSOZ, A., TOPSAKAL, N.
1. MARMARA UNIVERSITY, 2. YILDIZ TECHNICAL UNIVERSITY

Introduction: In modern dance technical movements with dynamic and static characteristics are used. Dancers must master those stylized movements in a consistent manner with minimal variability, while using different balance, postural and support conditions (1). Therefore modern dancers must have exceptional postural control to maintain balance and to display strength. For the dancers, it is important to have a strong stable support from the floor during technical movements. Performing barefoot in modern dance puts more emphasis on the foot type of the dancer. Foots are classified according to their shape and relative length of toe. Morton's Foot (MF) is a foot type where the second-toe is longer than the others (2). Having a longer second and shorter first metatarsal makes the foot less stable, especially in relevé position. Although, reports exist in literature which indicate that MF can cause calluses, injuries and pain in ballet dancers, and that it is a factor in the etiology of foot disorders (3), we couldn't find any study about the effects of MF on the performance of dancers. The aim of this study is to investigate the effects of MF on dynamic and static balance, and vertical jump performances of modern dancers.
Methods: 14 modern dancers (10 female, 4 male; average age 24,14±2.56 years; involvement in dancing 7.82± 5.52 years) participated in this study. The participants were divided into two groups (each 5 female, 2 male) according to the presence or absence of MF. In order to determine the foot type of the dancers, feet were photographed while joints were in neutral position. A second toe longer than the hallux by 2 mm or more was considered as MF. To determine the explosive power of the leg, two vertical jump tests were performed: the dancers performed squat jumps in parallel and in first position on an Ergojump platform. Static balance (SB) performance was determined using the Single-Leg-Stance test which was modified for the dancers (in turn-out passé, in relevé position). Dynamic balance (DB) was determined using a stabilometer platform (Model 16020, Lafayette).
Results: The squat jump height and the time to stay in SB with right foot and in DB were found to be higher for the non-MF group compared to MF group, but these differences were not statistically significant ($p>0.05$). However the non-MF group dancers were able to stay longer in balance on their left foot than the MF group (32.92±16.02 s versus 9.35±6.27 s) and this was statistically significant ($p<0.05$).

Discussion: Modern dancers with MF stayed shorter in balance on their left foot. It is concluded that MF could be a negative factor influencing the performance of static balance of modern dancers.

EFFECT OF GENDER ON ANAEROBIC POWER GENERATION CAPACITY DURING CYCLING EXERCISE.

TSUNODA, N., TANAKA, S., TAKAHASHI, Y., KUMAGAWA, D.

KOKUSHIKAN UNIVERSITY

Introduction: The maximal anaerobic power generation capacity is an important factor in many athletic activities. It is not clear that the effect of gender on characteristics of the load and the pedaling rate to the anaerobic power generation capacity during cycling exercise. Therefore, the purpose of this study was to investigate the gender difference of the anaerobic power generation capacity in cycling exercise with different loads.

Methods: The subjects were three hundred twenty one (201 male and 120 female) collegiate students of physical education. These subjects were six grouped according to body weight (male: M-LG, M-MG, M-HG., female: F-LG, F-MG, F-HG). The anaerobic power generation capacity was determined by using bicycle ergometer (Power max V2, Combi co. Japan) with custom-made analyzed system. Subjects performed ten seconds with the maximal efforts intermitted of three trials with first, second and third load stages, and requested to have warm-up and including two minutes rest. The anaerobic power generation capacity, workload and pedaling rate of cycling exercise on each trial measured in all the subjects. In addition, ratios of second stage and third stage to first stage trials were calculated for each parameter.

Results: The maximal anaerobic power generation capacity was obtained in groups of M-LG and M-MG, the anaerobic power generation capacities of second trial showed highest values compared with other trials. However, significant difference between second and third trial was not observed in M-HG. Moreover, the anaerobic power generation capacity between second and third trials was not differed in all the groups on female. The pedaling rate decreased with the increase of workload in both male and female for each stage. In workload ratio, M-LG and F-LG admitted by third stage trial. In case of M-MG and F-MG, the ratios of workload differed between male and female in both stages of second and third trials. The ratio of pedaling rate between M-HG and F-HG was significant difference on third stage trial.

Discussion: From these results, it considered that the maximal anaerobic power generated in the same stage of second trial in both male and female subjects. However, the effects of workload and pedaling rate on the anaerobic power generation capacity during cycling exercise may differed by gender.

BALANCE TRAINING ALTERS POSTURAL DYNAMICS UNIQUELY FOR STANCE ON COMPLIANT VS. NON-COMPLIANT SURFACES

WALSH, M., STRANG, A., HIERONYMUS, M., HAWORTH, J., SMART, L.

MIAMI UNIVERSITY

Balance training is a common clinical modality used for improving postural control and preventing injury. However, a number of empirical studies have failed to support the efficacy of balance training. One factor that may have limited the previous empirical studies is a lack of sensitivity with regard to the traditional descriptive statistics used to characterize postural control. Recent developments in non-linear dynamic analyses have led researchers to revaluate the way in which postural control is measured and understood. The advantage of nonlinear analyses for assessing postural behavior is their sensitivity to changes in the time-dependent structures of continuous postural sway. The purpose of this study was to evaluate the effects of balance training on postural control in a healthy population using both a traditional (position variability; as measured by standard deviation) and non-linear (Lyapunov Exponent; LyE) measure of postural sway variability. To accomplish this, eighteen participants completed a six-week balance training program (three sessions per week; eighteen total sessions). Pretest and posttest measurements of postural sway were obtained in the anterior-posterior (A/P) and medial-lateral (M/L) planes via Center of Pressure (COP) from a forceplate during upright bipedal stance performed on a hard and foam surface. Results showed that participants exhibited increased chaotic variability in the temporal structure of their postural sway in the M/L plane following balance training (as assessed via LyE) in stance performed on the noncompliant surface ($p = .053$), but decreased chaotic variability in the M/L planes in stance performed on the compliant surface ($p = .021$). In addition, results from traditional measures showed that participants exhibited an increase in A/P variability (as assessed via SD of COP position) following balance training, but only for the hard surface ($p = .019$). Together, these results imply that balance training results in changes to postural behavior which are specifically tailored to task demands and environmental constraints. While these findings seem to resonate with previous literature on dynamics systems theory, which respects the interdependence of human-environment interactions, and which has implied that increased chaotic variability may actually be an indicator of health/expertise in some circumstances, this interpretation is qualitative different from traditional theories of postural control and needs further development.

EFFECTS OF PLYOMETRIC TRAINING ON THE MECHANICAL AND GEOMETRICAL PROPERTIES OF THE PLANTAR FLEXOR MUSCLE-TENDON COMPLEX

FOURÉ, A., NORDEZ, A., CORNU, C.

UNIVERSITY OF NANTES

Introduction: Plyometric training (PT) has already been shown to increase vertical jump performances which could be attributed to changes in the mechanical properties of muscle-tendon complex (MTC) rather than muscle activation strategies (Kubo et al., 2007). Cornu et al. (1997) hypothesized a specific adaptation of the MTC structures as it was shown concerning the passive stiffness of plantar flexors

(Foure et al., 2008). The aim of this study was to determine the effects of PT on the stiffness of the structures involved in the ankle joint plantar flexion using an original method previously used in animal models (Ettema and Huijing, 1994) in order to assess possible specific local adaptations of their elastic properties.

Methods

Nineteen subjects divided in a trained (TG) and a control group (CG) were tested before and after the 14 weeks of a PT period. The jump performances were assessed. The ankle joint stiffness was determined during a stretch imposed on isometric PF randomly performed twice at 7 levels of torque (from 30% to 90% of maximal voluntary contraction (MVC)). Active joint stiffness was computed from the increase in torque relative to the change in ankle flexion angle for the first 60 ms of the stretch (approximately 7 degrees). The joint stiffness was determined for 40% (S40%), 60% (S60%) and 80% (S80%) of the minimal MVC between the two tests. Both the active and passive parts of series elastic component (SEC) stiffness were assessed using the alpha method. Cross-sectional area (CSA) of Achilles tendon was determined using ultrasonography.

Results: For the TG, a significant increase in jump performances was found (changes between +7.3% and +26.5% according to the jump form). An increase in the Achilles tendon CSA was found (+2.9%). The joint stiffness increased (S60%: +1.8% and S80%: + 2.7%) with an increase in the passive part of SEC stiffness (+ 7.8%) and a decrease in the active part of the SEC stiffness index (- 5.0%). Analyses on the CG data are still in process.

Discussion: The present study was based on the use of an original method to assess both the active and passive parts of the SEC stiffness. The major results showed an increase in the ankle joint stiffness with a different change between passive and active part of the SEC stiffness. Then, these opposite adaptations could be responsible for a better efficiency of the energy storage-recoil process by the MTC leading to an increase in jump performances. The adaptation seems to be attributed to changes in the geometrical properties of the involved structures rather than intrinsic mechanical properties of the structures.

EXTENSIBILITY OF THE HUMAN ACHILLES TENDON DURING ISOMETRIC CONTRACTION: AN IN VIVO MRI STUDY

IWANUMA, S., AKAGI, R., KURIHARA, T., IKEGAWA, S., KANEHISA, H., FUKUNAGA, T., KAWAKAMI, Y.

WASEDA UNIVERSITY

[Introduction] Extensibility of the human Achilles tendon has been studied in vivo, based on the partial deformation of a selected area [1, 2]. However, it has been shown that the Achilles tendon deforms inhomogeneously, with different strains between the external tendon and aponeurosis, both longitudinally and transversely [3]. The present study further examined the extension of the entire Achilles tendon during isometric contractions by using MRI. [Methods] Subjects were 12 healthy men (n = 6) and women (n = 6). The subject lay supine with the knee fully extended and the foot secured to a torque meter at neutral position. While a series of longitudinal and transverse MR images (thickness: 3 mm, spacing: 0 mm) of the Achilles tendon were taken, the subjects sustained 0 (rest), 30, 60 and 80% of the maximum voluntary contraction (MVC) of isometric ankle joint plantar-flexion. The length and width of the Achilles tendon were determined from each MR image, from which longitudinal and transverse strains were calculated. Additionally, the Achilles tendon was divided into proximal and distal portions at the distal end of the soleus muscle, and the length and width of each portion were measured. [Results] There was no longitudinal strain in the proximal portion of Achilles tendon from rest to 30%MVC, and there were significant positive strains at 60 and 80%MVC (1.4 and 1.8% respectively). Transverse positive strains of the proximal portion of the tendon were observed both at 30%MVC (12.3%) and 60%MVC (18.8%). As for the distal portion, the longitudinal and transverse strains of the tendon were significant at all intensities (30%MVC: longitudinal: 2.2%, transverse: -4.3%, 60%MVC: longitudinal: 3.0%, transverse: -4.9%, 80%MVC: longitudinal: 4.3%). [Discussion] The Achilles tendon extended inhomogeneously. The proximal portion of the tendon, which extended both directions, is mainly composed of the aponeurosis of the soleus muscle. It has been reported for animals and also for humans that the aponeurosis extends transversely upon isometric contractions [4, 5]. Because the directions of fascicles of the soleus muscle are not parallel to each other, or not to the longitudinal direction of Achilles tendon [6], soleus muscle fascicles might possibly pull the aponeurosis in multiple directions. In contrast, since the distal portion of Achilles tendon has no connection to muscle fibers, there would be no source of force in the transverse direction. We conclude that the extensibility of the Achilles tendon to force applied to it varies depending on locations, both longitudinally and transversely. A 6-WEEK STRETCHING PROGRAM ALTERS MECHANICAL AND ARCHITECTURAL PROPERTIES OF THE GASTROCNEMIUS MUSCLE-TENDON UNIT

KATO, E.

WASEDA UNIVERSITY, JAPAN SOCIETY FOR THE PROMOTION OF SCIENCE

Introduction: Stretching is known to increase the joint range of motion (ROM) both acutely and chronically, the reason for which is thought to be related to some changes in musculotendinous structures. While the acute effect of stretching on mechanical properties of a muscle-tendon unit (MTU) in humans has been documented, few studies have examined the long-term effect of periodical stretching sessions on MTU. The purpose of this study was to investigate changes in the mechanical and architectural properties of the human gastrocnemius MTU by a 6-week stretching program.

Methods

Sixteen healthy men participated in this study (stretching group, n=8, control group, n=8). The stretching program consisted of static stretching (1 min passive dorsiflexion performed 5 times) everyday for 6 weeks. Before and 1, 2, 4, and 6 weeks after the onset of the stretching program, the passive dorsiflexion ROM was measured by goniometry as well as muscle and tendon elongation by ultrasonography. To measure muscle and tendon elongation, an ultrasound probe mounted with a water bag was attached over the distal end of the medial gastrocnemius at the muscle-tendon junction (MTJ), so that longitudinal scanning was made along the length of the muscle. Muscle belly elongation was determined as the displacement to the distal of the MTJ. The change in total MTU length was estimated from

the change in ankle angle. The Achilles tendon elongation was calculated as the difference between elongations of the MTU and muscle belly. Negligible muscle activity during the stretching was confirmed through surface electromyograms taken from the medial and lateral gastrocnemii, soleus, and tibialis anterior muscles during stretching. The fascicle length (FL) was also measured in the mid-belly of the medial gastrocnemius using ultrasonography.
Results and Discussion: The passive dorsiflexion ROM increased significantly at the 4th week and later from the onset of the stretching program, which was accompanied by a significant increase in Achilles tendon elongation, especially in the dorsiflexed position. There was no further increase in muscle belly elongation in the dorsiflexed position. The plantar flexion torque passively attained at rest (0 deg of ankle joint) decreased significantly, while the FL increased significantly at the 4th week and later. This result indicates that the Achilles tendon elongation became smaller after the stretching program due to elongated fascicles and the muscle belly at rest at 0 deg of ankle joint. However, an increase in tendon elongation in the dorsiflexed position after the stretching program suggests a decrease in tendon stiffness, especially under higher passive tension. In conclusion, these results imply that the 6-week stretching program affects both mechanical and architectural properties of the gastrocnemius MTU, with different changes of muscular and tendinous components that are joint angle dependent.

DOES CYCLING INFLUENCE NEUROMUSCULAR CONTROL DURING SUBSEQUENT RUNNING IN LESSER-TRAINED TRIATHLTES?

BONACCI, J., CHAPMAN, A.R., BLANCH, P., VICENZINO, B.

UNIVERSITY OF QUEENSLAND, BRISBANE, AUSTRALIA., MCGILL UNIVERSITY, MONTREAL, CANADA., AUSTRALIAN INSTITUTE OF SPORT, CANBERRA, AUSTRALIA

Triathlon success depends primarily on a triathlete's ability to run after cycling. As the neuromuscular system effectively translates cardiorespiratory capacity into efficient movement and therefore into optimal performance, triathletes' performance relates closely to their ability to maintain neuromuscular control (muscle recruitment and movement patterns) that is specific to running and not adversely influenced by the preceding bike-leg1. However, a previous study has shown that running muscle recruitment is influenced by cycling in 36% of highly-trained triathletes2, despite their years of training. This altered muscle recruitment is due to a direct influence of cycling on neuromuscular control during running, is independent of fatigue, and is associated with a decrease in running economy and a 2.5 times greater likelihood of exercise related leg pain3. However, it is not known if cycling has the same direct influence on neuromuscular control during running in lesser-trained triathletes. PURPOSE To investigate the direct influence of cycling on running muscle activity and movement patterns in lesser-trained triathletes. METHODS 15 lesser-trained triathletes participated. 3-D kinematics of the pelvis and lower limbs and recruitment of 11 leg and thigh muscles were compared between a control run (no prior exercise) and a 30 min run that was preceded by a 15 min cycle (transition run). RESULTS Neuromuscular control was not different between control and transition runs, or differences were only transient, in most triathletes. Changes in joint position (mean difference of 3°) were evident in 5 triathletes, but these changes persisted beyond 5 min of running in only 1 triathlete. One triathlete displayed altered recruitment of the biceps femoris muscle (7.4% decrease in average amplitude over the running stride), which was not associated with a change in kinematics, and persisted for 20 min of the transition run. DISCUSSION Short periods of cycling have no direct influence on running muscle activity in most lesser-trained triathletes. Muscle recruitment during running was influenced by cycling in only 1 of 15 lesser-trained triathletes (< 7%), compared to 36% of highly-trained triathletes2, and the magnitude of this change was less than previously reported in highly-trained triathletes (7.4% vs. 10-20%). Cycling did cause some transient changes to running kinematics in 30% of lesser-trained triathletes. Our findings suggest that optimal neuromuscular control for running is preserved after cycling in lesser-trained triathletes. The differing influence of cycling on neuromuscular control during subsequent running in lesser-trained and highly-trained triathletes is likely related to training history.

RIGHT OR LEFT – IS THERE AN OPTIMAL INITIAL PRACTICE SIDE IN MOTOR LEARNING?

STÖCKEL, T.

UNIVERSITY OF LEIPZIG

Introduction: Findings from neurosciences indicate, that the two hemispheres in the human brain are specialized for the processing of distinct movement features (i.e. Serrien, Swinnen & Ivry, 2006). How this knowledge can be useful in motor learning remains unclear. In the present study two experiments on the acquisition of complex sports motor skills are carried out to prove the relation between the initial practice side and inherent task de-mands.
Methods
Within a transfer design two groups practiced a novel motor task with same amount of practice on each hand, but in opposite hand-order. Performance changes are measured on both sides separately after a practice period and after a period without practice. In experiment I subjects were asked to learn a throwing task with high demand on maxi-mum force production. Subjects initially practiced with their preferred hand and changed to the non-preferred (P-NP) benefited more from practice. In experiment II subjects were asked to learn a dribbling task with high demand on movement coordina-tion and speed. Subjects initially practiced this task with their non-preferred hand before changing to preferred hand (NP-P) benefited more from practice than subjects practiced in opposite order.
Results & Discussion: The results indicate, that tasks with high demand on spatial accuracy and movement coordination are learned better through initial practice with the non-preferred hand, whereas initial practice with the preferred hand seems to be more efficent for tasks with high demand on maximum force production. These findings suggest a strong relation between the initial practice side and the hemispherical specialization for different task demands. The present findings can be used to optimize early motor learning processes.

NO DIFFERENCE ON THE LEVEL OF PGC1A MRNA EXPRESSION AFTER TWO RADICALLY DIFFERENT HIGH INTENSITY TRAINING SESSIONS IN HIGHLY TRAINED CYCLISTS

WESTERGREN, J., PSILANDER, N., WANG, L., KNUTSSON, M., SAHLIN, K., TONKONOGI, M.

1. LIVI, HÖGSKOLAN DALARNAS IDROTTSVETENSKAPLIGA INSTITUT, 2. ÅSTRANDLABORATORIET, GIH.

In recent years a number of studies on high intensity interval training have shown that a very limited number of wingate type intervals performed over only a few weeks can improve endurance performance dramatically. Since PGC1a is a major regulator of mitochondrial biogenesis, we hypothesized that there would be no difference in PGC1a mRNA expression between wingate type intervals and longer lower intensity intervals.

The aim of this study was to compare the impact on the level of PGC1a mRNA expression of two radically different high intensity interval training sessions in highly trained cyclists. Ten male cyclists, (mean±SD) age 24.7± 4.4 years, height 179.1±4.8 cm, weight 70.1±6.2 kg, VO2peak 4753±470 ml min-1, Wmax 403±40 W volunteered for the study. After a standardized 15 min warm up, the subjects performed the following radically different high intensity interval training sessions, on a Cyclus 2 ergometer, 7-9 days apart in a counterbalanced fashion. The short interval high intensity training session consisted of 7 maximal 30 seconds isocadence sprints at 110 rpm separated by 4 minutes of active recovery at 50W. The long interval high intensity training session consisted of 3 time trials of 20 minute duration separated by 4 minutes of active recovery at 50W. Subjects were instructed to try and achieve to highest possible average power during all three intervals. The effective work duration for the short and long intervals was 3.5 minutes and 60 minutes respectively. Needle biopsies were obtained from M.Vastus Lateralis muscle at 15 minutes prior to the training session and 3 hours after completion of the training session.

Average power output, capillary blood lactate levels and PGC1a mRNA expression of the short and long high intensity training session was 643±71 W, 14.9±2.4 mmol L-1, 6.03±1.8 fold change and 304±38W, 4.4±1.3 mmol L-1, 6.59±2.45 fold change respectively, with significant differences between the two sessions for power output and blood lactate levels but not for PGC1a mRNA expression.

Despite the radical difference of the high intensity training sessions in terms of power output and blood lactate levels there is no difference in PGC1a mRNa expression. Meaning that both types of high intensity training sessions may provide similar stimuli for mitochondrial biogenesis.

THE SATELLITE CELL RESPONSE TO AN ACUTE BOUT OF OCCLUSION EXERCISE.

NILSEN, T., WERNBOM, M., PAULSEN, G., KOSKINEN, S., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Low load exercise with vascular occlusion has attained increased interest the last years due to the observed effects on muscle hypertrophy (Wernbom et al 2008). Although the potential to induce muscle growth over a training period has been well documented, the effects of occlusion exercise on the cellular level remains to be investigated. Because satellite cells (SC) are important for skeletal muscle hypertrophy and the satellite cell expresses myogenic regulation factors (MRFs) upon activation, the aim of this study was to investigate the effect of one bout of occlusion exercise on the number of SC and the number of SC expressing either MyoD or myogenin.

Methods: Nine subjects completed one bout of unilateral knee extension with five sets till failure with a load representing 30 % of 1 RM. One leg completed the bout with partial vascular occlusion provided by an inflatable pressure cuff. The other leg preformed a repetition-matched bout, and thus served as a non occluded control. Maximal isometric voluntary contraction force (MVC) was measured before exercise and repeatedly for one week after the bout. Biopsies were obtained pre-exercise, control leg only, 1 h-, 24 h- and 48 h post exercise from both legs. Cross sections from the biopsies were stained with antibody against NCAM, which recognises SC, and counter-stained with antibodies against MyoD or myogenin, on neighbour sections. SC was counted as NCAM positive ring like staining in close relation to the muscle fibre. MyoD- og myogenin positive SC were identified as MRF positive staining inside the SC.

Results: Immediately after exercise there was a lager reduction in MVC force in the occluded leg than in the non occluded leg. Four hrs after exercise this difference was reduced, but the occluded leg generated less force throughout the recorded period compared to the control leg. Our data indicates a tendency towards an increased number of SC expressing one of the two MRF's. There were no differences in the increase of SC between the two legs. However, when combining the two legs an increased number of SC per fibre was observed one hour after exercise, and the number remained increased throughout the 48 h period.

Discussion: An increased number of SC expressing MRF indicates a SC response to the exercise. The immediate increase in number of SC per fibre is an interesting observation, and to our knowledge this has not been described earlier. However, it's rather unlikely that this is due to a real increase in the number of SC per whole muscle fibre; it's more likely that it's a methodical issue. One explanation could be an increased SC volume in activated SC, leading to in an increased number of counted SC per cross section. In further analysis we will elucidate the possible mechanisms for the early increase in the number of SC and further describe the time course of activated satellite cells after low load occlusion exercise.

AGE ASSOCIATED INCREASE IN SIRT1 AND SIRT6 CONTENT ATTENUATED BY EXERCISE IN RAT SKELETAL MUSCLE

KOLTAI, E., SZABO, Z., KANEKO, T., NAITO, H., GOTO, S., NYAKAS, C., RADAK, Z.

SEMMELWEIS UNIVERSITY

Sirtuins suggested to be one of the key regulators of aging process, and the dependence of these proteins on NAD+, makes them a potential marker of cellular metabolism. Regular physical exercise results in a metabolic and redox challenge to skeletal muscle which at

certain degree can attenuate the age-associated loss in muscle function. Young control (YC), exercised (YE) and old, control (OC) and exercise (OE) rats were used, with six weeks of treadmill running program at the 60% of VO2max. Aging resulted in increased level of SIRT1 in cytoplasm and nuclear extracts, while exercise training significantly increased the relative activity of SIRT1 in both age groups. The levels of nicotinamide phosphoribosyltransferase (NAMPT) and NAD+ significantly degreased with aging, which were prevented by exercise training. Both, aging and exercise training modified the level of acetylation in number of proteins. The oxidative challenge was evaluated by accumulation of carbonyl groups, which increased at OC, and 8-oxydeoxyguanosine level of nuclear extracts, which did not change. On the other hand, the content of SIRT6, which suggest to influence base excision repair increased with aging in parallel with the content of 8-oxoguanine DNA glycosylase (OGG1). Aging resulted in massive increase in the content of hypoxia inducible factor alpha (HIF-1alpha) and vascular endothelial factor (VEGF), which was prevented by exercise training.

Aging of the skeletal muscle is associated with inadequate production of NAD+ because of impaired synthesis via NAMPT, although the activity of SIRT1 does not change with aging.

Hence, NAMPT emerged as possible therapeutic target to attenuate aging process in skeletal muscle, suggesting metabolic and partly reversible consequences of aging, as regular exercise, decreased the gap in all between young and old groups.

ESTROGEN REGULATES SATELLITE CELL ACTIVATION FOLLOWING A NOTEXIN-INDUCED SKELETAL MUSCLE INJURY

VELDERS, M., FRITZEMEIER, K.H., DIEL, P.

GERMAN SPORTS UNIVERSITY COLOGNE, INSTITUTE OF CARDIOVASCULA

Skeletal muscle repair processes are mediated by the coordinated response of inflammatory immune cells and satellite cells. It has been reported that estrogen activates satellite cells in skeletal muscle damaged by high intensity downhill running exercise and that this process is ER-mediated (Tiidus, Holden et al. 2001; Tiidus, Deller et al. 2005; Enns, Iqbal et al. 2008; Enns and Tiidus 2008). To prove that estrogen may also activate satellite cell activity in a skeletal muscle injury model relevant to pathological processes involved in inflammatory dystrophic skeletal muscle diseases or sarcopenia, we analyzed the effects of estrogen in a myotoxin (Notexin) based skeletal muscle injury model. This model is known to cause an early inflammatory reaction followed by a satellite cell driven repair period. Female Wistar rats were divided into three experimental groups: intact (SHAM), ovariectomized (OVX) and ovariectomized E2 substituted animals (E2). We investigated the effects of subcutaneous (E2) replacement for 7 days on immune and satellite cell activation. Results show that protein expression levels detected by western blot analysis of the proliferating cell nuclear antigen (PCNA) are highest in the toxin-damaged m.Gastrocnemius (m.GAS) of OVX rats compared to control (Sham) and E2-substitued groups, 24-h following the injury. A different PCNA expression pattern was detected 3-d after Notexin injections into the right m.GAS. Here, PCNA expression was highest in the right m.GAS of Sham and E2 animals compared to OVX animals. This differential expression pattern of PCNA could be due to the proliferation and infiltration of inflammatory immune cells into the injured m.GAS after 24-h. The increased expression of PCNA in the right m.GAS of Sham and E2 animals after 3-days may be the result of increased satellite cell proliferation. Gene expression data confirms that the expression of the satellite cell marker Pax-7 is highest in the right m.GAS of Sham and E2 treated groups compared to OVX. Protein expression levels of the inflammatory cytokine tumor necrosis factor alpha (TNFα) are elevated 24-h post-injury in the right m.GAS of all treatment groups and are below detection levels after 3 days. In summary, our results show that estrogen replacement increases satellite cell numbers following a toxin-induced skeletal muscle injury. Based on this information we speculate that normal E2 serum levels may provide protection against inflammatory dystrophic diseases and sarcopenia, whereas reduced E2 serum levels may promote the development of these diseases. Further studies are in progress to investigate whether these mechanisms are estrogen receptor alpha or beta mediated.

COMBINED TREATMENT WITH INSULIN AND EXERCISE TRAINING AMELIORATES EXPRESSION OF CALCIUM SIGNALLING PROTEINS IN STREPTOZOTOCIN-INDUCED DIABETIC RAT HEARTS.

LE DOUAIRON LAHAYE, S., MALARDÉ, L., ZGUIRA, M.S., VINCENT, S., LEMOINE MOREL, S., ZOUHAL, H., DELAMARCHE, P., CARRÉ, F., RANNOU BEKONO, F.

LABORATORY MOUVEMENT SPORT SANTÉ

Background – Insulin therapy and regular exercise activity have positive impact on the diabetic cardiomyopathy, where impaired contractile responsiveness to β-adrenergic stimulation results in part from alterations in the Ca2+ regulatory systems. If the cellular and molecular mechanisms involved in insulin or exercise training myocardial adaptations have been partially explained, the concomitant effects of these 2 approaches remains incompletely characterized. So, the present study was undertaken to assess the combined effects of insulin treatment and exercise training on Ca2+ signalling proteins expression on heart of diabetic rats.

Methods – Type 1 diabetes was induced by a single intraperitoneal injection of streptozotocin (STZ, 45 mg/kg, in citrate buffer) in adult male Wistar rats. One week after STZ injection, diabetic rats were randomly divided into 3 groups: non-treated diabetic, insulin-treated diabetic, and trained insulin-treated diabetic animals. Exercise training consisted of progressive running at speeds to 25 m/min, 60 minutes/day, 5 days/week for 8 weeks on a rodent treadmill set at 10°. A group of normal sedentary rats served as control. Abundance of Ca2+ signalling proteins was assessed using Western blots. Langendorff left ventricular performance was also determined.

Results – After nine weeks of diabetes, SERCA2, RyR2 and NCX1 protein expression were significantly reduced by 32, 44, 23%, respectively, whereas PLB expression was significantly elevated (46%) and FKBP 12 unchanged. Intrinsic contractile parameters were also significantly reduced. Insulin treatment initiated after 1 week of diabetes normalized the expression of SERCA2, RyR2, and NCX1, and attenuated the loss in cardiac relaxation and contraction as assessed by ±dP/dt. Moreover, training accentuated positive insulin-treatment effects because trained insulin-treated diabetic animals exhibited significantly higher SERCA2, RyR2, and NCX1 protein expression and RyR2/FKBP12 ratio than insulin-treated diabetic animals. Although the difference were not significant, positive and negative dP/dt were increased (19 and 8%, respectively), by the association exercise training-insulin compared with insulin alone.

Conclusion – Taken collectively, these data suggest that the beneficial effect of insulin treatment in the expression of the main Ca2+ signalling proteins could be potentiated by exercise training. Moreover, these adaptations might lead to normalise cardiac contractile efficiency. So this study provides additional funding as to the beneficial role of exercise in the management of diabetes.

THE ENZYMES OF INTRAMUSCULAR TRIGLYCERIDE SYNTHESIS EXHIBIT FIBRE TYPE SPECIFICITY.

CLARK, J., SHAW, C.S., WAGENMAKERS, A.J.M.

UNIVERSITY OF BIRMINGHAM

Introduction: Excessive fatty acid (FA) uptake in skeletal muscle is known to lead to insulin resistance in sedentary obese individuals. The underlying mechanism involves the accumulation in muscle of long-chain FAcylCoA and diacylglycerol. These FA metabolites activate protein kinase Cβ and this leads to serine phosphorylation and inactivation of insulin receptor substrate-1. Intramuscular triglycerides (IMTG) accumulate in skeletal muscle as discrete lipid droplets that fill the space between mitochondria. The key enzymes in IMTG synthesis are glycerol-3-phosphate acyltransferase (GPAT) (which exists in a mitochondrial (mt) and a microsomal (mic) isoform) and diacylglycerol acyltransferase (DGAT). These enzymes catalyse acylations that consume the FA metabolites that lead to insulin resistance. An increase in the content of mtGPAT and DGAT has recently been observed in the muscle of non-obese women the day after a single bout of endurance exercise and was shown to prevent lipid induced insulin resistance. The aim of the present study was to develop methods that for the first time allow us to investigate the spatial and fibre type distribution of mtGPAT, micGPAT and DGAT in human skeletal muscle.

Methods: Percutaneous biopsies were obtained from the vastus lateralis muscle of 6 lean, insulin sensitive males. 5 µm cryosections were stained using either rabbit anti-DGAT IgG, rabbit anti-mtGPAT IgG or rabbit anti-micGPAT IgG antibodies, each in combination with mouse anti-myosin heavy chain (MHC) type 1 IgM. IMTG were stained using the neutral lipid dye oil red O (ORO) and images were viewed using widefield fluorescence microscopy.

Results: Cryosections stained for mtGPAT in combination with MHC and ORO revealed a two-fold higher lipid content in type 1 fibres ($P < 0.020$). This corresponded to those fibres with the strongest mtGPAT signal ($P < 0.001$). Anti-DGAT staining showed a diffuse pattern of staining in all fibres with a significantly stronger signal in type 1 fibres ($P < 0.001$). The greater DGAT signal corresponded to those fibres with a two-fold higher lipid content ($P < 0.014$). Anti-micGPAT staining showed a diffuse signal throughout both type 1 and type 2 fibres.

Discussion: These results demonstrate that type 1 fibres have a higher content of the enzymes of IMTG synthesis than type 2 fibres which is in line with the observation that type 1 fibres contain more IMTG whilst being more insulin sensitive. The low content of mtGPAT in type 2 fibres despite the presence of IMTG suggests that micGPAT is responsible for IMTG synthesis in these fibres. In future studies we will investigate the distribution of these enzymes in biopsies of obese individuals and patients with type 2 diabetes and the effect of various modes of exercise with the aim to better understand the relationship between muscle IMTG synthesis and fibre type specific differences in insulin sensitivity between these populations.

EFFECT OF CONTRACTION AND INSULIN ON GLUCOSE UPTAKE AND GLYCOGEN SYNTHASE IN MUSCLES WITH DIFFERENT GLYCOGEN CONTENTS.

LAI, Y., ZARRINPASHNEH, E., LIN, F., JENSEN, J.

NATIONAL INSTITUTE OF OCCUPATIONAL HEALTH

Background: Insulin and contraction stimulate glucose uptake and glycogen synthase through different mechanisms in skeletal muscle. Furthermore, glycogen content is a potent modulator of glucose uptake and glycogen synthase activity when muscle was exposed to insulin or contraction stimulation. An additive effect of insulin and contraction is often reported in muscle with normal glycogen content; however, it has not been well studied in muscles with low and high glycogen contents.

Aim: Our aim was to systemically investigate the effect of glycogen content on glucose uptake and glycogen synthase activity in muscles stimulated by insulin and contraction alone or in combination.

Method: Glycogen content in rat muscles was manipulated by fasting and fasting followed by refeeding. After manipulation, epitrochlearis muscles with low (LG), normal (NG), and high (HG) glycogen contents were dissected and mounted on contraction apparatus for in vitro studies. Muscles were either kept rested in the absence or presence of insulin for 30 min or contracted in the absence or presence of insulin for 30 min. Glucose uptake was measured during the incubation and glycogen synthase fractional activity and phosphorylation were measured after 30 min of contraction.

Results: Insulin and contraction additively stimulated glucose uptake in NG and HG but not in LG. Nevertheless, glucose uptake was higher in LG than in NG and HG during insulin and contraction stimulation alone or in combination. Contraction-stimulated AMPK activity and insulin-stimulated PKB phosphorylation was higher in LG than in NG and HG. However, AS160 (probably included TBC1D1) phosphorylation was not correspondingly elevated in LG. Contraction and insulin also additively increased glycogen synthase fractional activity in NG and HG but not in LG. Glycogen synthase phosphorylation at Ser641 was decreased by insulin and contraction. Furthermore, glycogen synthase Ser641 phosphorylation was inversely correlated with glycogen synthase fractional activity ($R = -0.92$, $p < 0.001$) when modulated by contraction, insulin and glycogen content alone or in combination. Glycogen synthase Ser7 phosphorylation was increased by contraction and was not regulated by insulin.

Conclusion: Contraction and insulin additively increase glucose uptake and glycogen synthase activity in muscles with normal and high glycogen content, but not in muscles with low glycogen content. Moreover, glycogen synthase Ser641 phosphorylation describes the physiological activity of glycogen synthase in muscle. Contraction-mediated glycogen synthase Ser7 phosphorylation does not prevent glycogen synthase activation.

BODY WEIGHT-BEARING RESISTANCE TRAINING PREVENTS SARCOPENIA IN OLDER WOMEN OF THE XX GENOTYPE OF ACTN3 POLYMORPHISM: THE FOUR-YEAR INTERVENTION STUDY

ZEMPO, H., TANABE, K., MURAKAMI, H., MAEDA, S., KUNO, S.

GURADUAT SCHOOL OF COMPREHENSIVE HUMAN SCIENCES

Introduction: It is important that maintenance of muscle mass for older adults. However, muscle mass decreases with aging, i.e., sarcopenia. The previous studies showed resistance training is beneficial program in the prevention of sarcopenia, and even low-intensity resistance training (e.g., body weight-bearing resistance training) could increase muscle mass in older adults.

Alpha-actinin-3 (ACTN3) is structural proteins of the Z-line and is expressed in only type II fibers of muscle. We have demonstrated that XX genotype of ACTN3 gene R577X polymorphism has less thigh muscle cross-sectional area (CSA) compared with other genotypes of ACTN3 in Japanese older women (13th Annual ECSS congress, Portugal, 2008). Furthermore, other study group reported XX genotype has less muscle mass in Caucasian women (Walsh et al., J Appl Physiol 2008). Thus, ACTN3 R577X polymorphism influence muscle mass.

However, it is unclear whether low-intensity resistance training prevents the loss of muscle mass in older adults with XX genotype of ACTN3.

Purpose: The present study was designed to investigate whether body weight-bearing resistance training prevents the loss of muscle mass in postmenopausal women with XX genotype of ACTN3.

Methods: The subjects consisted of twenty healthy Japanese postmenopausal women (means ± SD, 63.7 ± 4.3 years). The study conformed to the principles outlined in the Declaration of Helsinki. Subjects underwent the eight body weight-bearing resistance training (knee extension, sit-up, push-up, back extension, leg curl, high knee, squat and hip extension), and walking or bicycle Ergo meter exercise for 4 year, 5 times per week at a fitness center of University of Tukuba and their home. Thigh muscle CSA was measured using magnetic resonance image (MRI) before and four-year after exercise training. ACTN3 R577X genotype was determined using real-time PCR with DNA extracted from blood.

Results: The distribution of RR, RX and XX genotypes in the study was 4, 9 and 7, respectively. XX genotype has less thigh muscle CSA compared with RR & RX genotype at pre training (XX: 69.9 ± 14.1 cm^2, RR&RX: 84.1 ± 10.3 cm^2, P = 0.018). XX genotype maintained their thigh muscle CSA, but not decrease at four year after training (Pre ＝ 69.9 ± 14.1 cm^2，Post = 75.3 ± 9.3 cm^2； P = 0.133).

Conclusions: This study suggests that body weight-bearing resistance training benefit for XX genotype who genetically less muscle mass. We consider that the results become important data for tailor-made training program regard with gene information in a future.

PP-TT17 Training and Testing 17

INFLUENCE OF VIBRATION TYPE, FREQUENCY, BODY POSITION, AND ADDITIONAL LOAD ON THE NEUROMUSCULAR ACTIVITY DURING WHOLE BODY VIBRATION

RITZMANN, R., KRAMER, A., GOLLHOFER, A., GRUBER, M.

ALBERT-LUDWIGS-UNIVERSITÄT FREIBURG, UNIVERSITÄT POTSDAM

Introduction: Despite the substantial amount of articles concerning whole body vibration (WBV), there are few that address fundamental questions such as optimal frequency, amplitude or body position on the training device (Abercromby et al., 2007).

Since vibration training is a form of training where the muscle is externally driven, the "motor" (i.e. the vibration device) and its adjustment (i.e. the choice of frequency and amplitude) has a big influence on the muscles' response to the training.

Methods: The electromyographic activity of the soleus (Sol), gastrocnemius medialis (GM), tibialis anterior (TA), rectus femoris (RF), vastus medialis (VM) and biceps femoris (BF) muscles were measured in ten healthy subjects during WBV. The independent variables were vibration type (rotational (RV) and vertical vibration (VV)), vibration frequency (5, 10, 12.5, 15, 20, 25 and 30Hz), body position (knee angles of 5, 30 and 60°; two different foot positions: forefoot vs. normal stance, i.e. heel and forefoot in contact with the vibration platform) and load (no load vs. an additional load equal to 1/3 of the body weight). The statistical analysis consisted of an ANOVA and paired t-tests.

Results: Vibration type: significantly ($p<0.01$) enhanced EMG activity during RV compared to VV in all recorded muscles.

Vibration frequency: the higher the frequency, the higher the EMG activity of all recorded muscles ($p<0.01$).

Body position: changing the knee angle from 5° to 30° to 60° resulted in successively increasing EMG activity in RF (+47% p=0.04; +28% p=0.001) and VL (+55% p=0.02; +52% p=0.04), whereas the muscular activity of Sol, GM and BF were reduced. Forefoot stance resulted in significantly increased neuromuscular activity only for the dorsal extensors compared to normal stance (Sol +51% and GM +72% $p<0.001$), whereas TA (+60% $p<0.001$), RF (+68% p=0.01), VM (+54% p=0.04) and BF (+25% p=0.03) showed enhanced activation during normal stance.

Additional load during WBV resulted in significantly enhanced neuromuscular activation in Sol (+21% $p<0.001$), GM (+31%p=0.01), RF (+18% $p<0.001$), VM (+29% p=0.02) and BF (+52% p=0.02).

Discussion: RV resulted in higher EMG activation than VV despite allegedly identical parameters, which is most likely due to the specific WBV device, described by the subjects as "massage-like". The clear influence of the frequency was to be expected, considering the function of WBV as an external drive to the muscles. The increased activity of VM and RF with increasing knee angle is understandable given their anatomical properties. Likewise, the damping effect of the ankle joint explains the activity pattern when the foot position varies.

THE RELATIONSHIP BETWEEN ANTHROPOMETRY, PHYSICAL FITNESS AND UPHILL LOAD CARRIAGE

GORMASZ, CH., ZEILINGER, M., BARON, R.

UNIVERSITY OF VIENNA

Introduction: Uphill load carriage is a key element in dismounted military operations in alpine terrain and demands a high level of physical fitness. However, testing staff directly on the criterion task is not usually practicable (e.g. safety, logistic etc.). Therefore the objective of this study was to determine the relationship between anthropometric parameters, physical fitness tests and uphill loaded marching performance in the field with loads of different weight.

Methods: Fourty-six male soldiers (age: 22.2 ± 2.5 yrs, body height: 179.7 ± 6.0 cm, body weight: 77.8 ± 7.4 kg, body fat: 15.9 ± 4.4%, VO2max: 51.3 ± 2.0 ml/kg/min) completed a test battery consisting of anthropometric, strength/power and aerobic fitness tests. Furthermore two 5.68 km loaded marches (1.43 km flat and 4.25 km with a vertical gain of 390 m) with a 20 kg (LM20) respectively 30 kg (LM30) backpack were conducted on two non-consecutive days. Participants started individually and were encouraged to complete as fast as possible by walking only.

Results: Time to complete LM20 was 65.76 ± 6.32 min (average speed: 5.18 ± 0.50 km/h) respectively 77.46 ± 11.36 min (average speed: 4.40 ± 0.65 km/h) for LM30. Significant correlations ($p < .05$) were found between LM20 time and strength/power (bench press power: $r = -.39$, bench row power: $r = -.32$) and aerobic fitness measurements (Queen's College Step Test: $r = .36$, 1.5 mile run: $r = .30$). Besides significant correlations existed between LM30 and anthropometric (fat-free mass: $r = -.60$, body height: $r = -.42$, leg length: $r = -.38$, body fat: $r = .38$, body weight: $r = -.36$), strength/power (bench press power: $r = -.51$, bench row power: $r = -.47$, sit-ups: $r = -.34$, back extensions: $r = -.32$) and aerobic fitness variables (1.5 mile run: $r = .57$). Stepwise multiple regression analysis was performed to generate prediction equations for both loads. The best model for LM20 (adjusted R-square = .22, $F = 7.222$, $p = .002$, SEE = 5.64, Beta(bench press power) = -.351, Beta(Queen's College Step Test) = .317) was LM20 (min) = 49.913 - [0.043 * bench press power (Watt)] + [0.185 * Queen's College Step Test (bpm)]. For LM30 the most accurate estimation (adjusted R-square = .53, $F = 25.472$, $p < .001$, SEE = 7.89, Beta(fat-free mass) = -.491, Beta(1.5 mile run) = .447) revealed the following equation: LM30 (min) = 45.731 - [0.962 * fat-free mass (kg)] + [9.498 * 1.5 mile run (min)].

Conclusion: Results of this study indicate that variables of physical fitness relate to uphill load carriage performance. The influence of these parameters increased when the carried load was augmented. Moreover, anthropometric parameters became relevant. Models for each load included an index of aerobic fitness and certain parameters linked to muscle mass. Anyhow the regression equation for the heavier load caused a higher explained variance. Loaded marching performance seems too complex and inconsistent to be assessed by unspecific surrogate tests.

INFLUENCE OF GENDER ON PACING ADOPTED BY ELITE TRIATHLETES DURING A COMPETITION

LE MEUR, Y., HAUSSWIRTH, C., BRISSWALTER, J., BERNARD, T.

UNIVERSITY OF TOULON-VAR

Purpose

The aim of the present research was to improve the description of the pacing strategies adopted by female and male elite triathletes during a World Cup triathlon and to discuss possible factors influencing the self-selection of such strategies.

Methods : Twelve elite triathletes (6 females, 6 males) performed three maximal tests: an all-out 400-m front-crawl to determine their swimming maximal heart rate (swimming HRmax), an incremental cycling test during which power output (PO), heart rate (HR), at ventilatory thresholds (VT1, VT2), maximal aerobic power (MAP) were assessed, and an incremental running test to evaluate their maximal running HRmax. Throughout a World Cup short distance competition, speed and HR were measured. The amount of time spent below 10% of PO (zone 1), between 10% MAP and PO at V1 (zone 2), between PO at VT1 and VT2 (zone 3), between PO at VT2 and MAP (zone 4) and above MAP (zone 5) was analyzed during the cycling leg.

Results : Swimming and running speeds decreased similarly for both genders ($P < 0.05$) and HR values were similar through the whole race (92±2% and 92±3% HRmax for women and men, respectively). The distribution of time spent in the 5 intensity zones during the cycling leg was the same for both genders (17 ± 5% and 17 ± 3% for zone 1, 36 ± 5% and 31 ± 5% for zone 2, 13 ± 2% and 19 ± 7% for zone 3, 13 ± 6 and 14 ± 3% for zone 4, 22 ± 2% and 19 ± 2% for zone 5 for women and men, respectively). Men's speed and PO decreased after the first bike lap ($P < 0.05$) and women spent more relative time above MAP in the hilly sections (45±4% vs. 32±4%). Men's running speed decreased significantly over all the circuit, whereas women slowed only over uphill and downhill sections ($P < 0.05$).

Conclusion : The main finding of this study was that both female and male elite triathletes adopted similar positive pacing strategy during swimming and running legs. On the contrary, men pushed the pace toughly during the swim-to-cycle transition in contrary to women and female triathletes were more affected by changes in slope during both cycling and running phases. These effects of gender on pacing may have strong implications for the differentiation of training for female and male elite triathletes.

NON-FUNCTIONAL OVERREACHING IN YOUNG SWIMMERS OVER AN 8-MONTH COMPETITIVE SEASON

MATOS, N., WILLIAMS, C., WINSLEY, R.

CHILDREN'S HEALTH & EXERCISE RESEARCH CENTRE, SCHOOL OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF EXETER, EXETER, UK

Little is known about the relationship between training load and non-functional overreaching (NFOR) in child swimmers. Due to the multifactorial nature of NFOR, previous work has recommended a multidisciplinary framework to address this topic (Matos and Winsley, 2007). The purpose of our study was to follow a group of young swimmers over an 8-month competitive season and assess the relationship between training load and the occurrence of NFOR, and its association with physiological and psychological measures. Seven national-level swimmers (3 males and 4 females) with a mean age of 15.4±1.0 yr volunteered to participate. Training load was monitored over the 8 month period using the stress index scale (Mujika et al., 1995). Data collection was performed monthly and involved determination of Immunoglobulin A (IgA) and cortisol (C) levels from a salivary sample, and the completion of the Training Distress Scale (TDS; Raglin and Morgan, 1994). Incidence of upper respiratory tract infections (URTI) was also recorded. A submaximal 7x200m step test was performed 2 times during the 8-month period with blood lactates, heart rates and rates of perceived exertion collected. Athletes were classified as NFOR if their competitive performance (main swimming event calculated by the 2004 FINA International Points Score) had stagnated or decreased over a period of weeks to months (Meuusen et al., 2006). Of the 7 athletes, 2 females (F3 and F4) were classified as NFOR. Competitive performance had stagnated/ decreased for more than 6 months (F3's performance stayed the same and F4 had a 6% decrement, even though they continued to train); all other athletes improved performance (8±9.8 % improvement) during the season. The NFOR swimmers monthly swim mean volumes (6-month NFOR period) were 31% (F3; 11.4km) and 22% (F4; 31.7km) greater compared to the non NFOR swimmers (8-month period). There was no evidence of higher mean cortisol in the NFOR swimmers (NFOR period) compared with the non-NFOR swimmers (8-month period). Absolute IgA and the incidence of URTIs did not show conclusive results on the F3 and F4 swimmers. TDS scores relative to the 6-month NFOR period were 54% (F3; 2.8) and 32% (F4; 1.9) greater than those of the non-NFOR swimmer (8-month period). The submaximal performance test data displayed no clear association with NFOR. These data indicate that young swimmers may become NFOR and that high training volumes may be implicated. Furthermore, high TDS scores may be useful

in identifying young swimmers at risk of NFOR, but measures of cortisol, IgA or URTI incidence rates have limited confirmatory use. Non-functional overreaching in children is a complex phenomenon and requires more research into the underlying causes for the development of applied diagnostic tools.

EFFECTS OF TAE-BO EXERCISE PROGRAM ON BLOOD MARKERS OF OXIDATIVE STRESS IN YOUNG WOMEN

STOJILJKOVIC, N., RADOVANOVIC, D., VESELINOVIC, N., IGNJATOVIC, A.

1. FACULTY OF SPORT AND PHYSICAL EDUCATION, UNIVERSITY OF NIS, SERBIA, 2. FACULTY OF PEDAGOGY JAGODINA, UNIVERSITY OF KRAGUJEVAC, SERBIA

Introduction: Strenuous physical exercise characterized by a remarkable increase in oxygen consumption with concomitant production of ROS presents a challenge to the antioxidant systems (Radovanovic et al., 2004). The risk of oxidative stress with exercise depends on exercise intensity and the participant's state of training (Alessio et al., 2000). This study examined the effects of 10 weeks tae-bo training on selected markers of oxidative stress in young women.

Methods: Blood samples were collected from seven women (mean+/-SD: age 26.8+/-4.3 years, body height 1.65+/-6.7 m, body weight 58.4+/-9.8 kg, body fat 15.1+/-6.4%) who performed tae-bo training as high-intensity aerobic exercise. The experimental program was consisted from three training sessions every week. This made total of 30 training sessions. Each training session lasted one hour. After the warm-up the main part of the training was consisted from the combination of tae-bo exercises. The choreographies were made from next tae-bo basic moves: jab, hook, cross, upper-cut, kick (front, side and back). Cross train with other forms of exercise such as walking, jogging, knee up, leg curls, step touch, etc. Intensity in the main part of training is adjusting to held heart rate frequency (HRF) in range between 60-85% of maximal HRF. Samples were analyzed for lipid peroxidation byproduct malondialdehyde-MDA, enzyme catalase-CAT, reactive carbonyl derivates, total sulfhydryl groups-TSHG and total antioxidant status–TAS (Sachdev and Davies, 2008). Blood markers of oxidative stress were determined by standardized spectrophotometry techniques.

Results: An important finding in present investigation is that TAS increased significantly after 10 weeks tae-bo training (median 78.2% pre vs. 82.4% post, $p<0.05$). There were no significant changes in CAT (median 25.14 IU.L-1 pre vs. 23.82 IU.L-1 post, $p>0.05$), erythrocyte MDA (median 13.6 µmol.L-1 pre vs. 13.63 µmol.L-1 post, $p>0.05$), TSHG (median 229.7 mM.L-1 pre vs. 219.18 mM.L-1 post, $p>0.05$), reactive carbonyl derivates (median 1.31 µM.g-1 of proteins pre vs. 0.91 µM.g-1 of proteins post, $p>0.05$).

Discussion: This data suggest that 10 weeks tae-bo exercise training increase serum total antioxidant status. Also, it can be concluded that tae-bo training program did not have other effects on oxidative stress levels in young women.

SEASONAL VARIATION IN PHYSICAL FITNESS AND FUNCTIONAL PARAMETERS OF PROFESSIONAL ELITE SOCCER PLAYERS

SILVA, J., MAGALHÃES, J., ASCENSÃO, A., SEABRA, A., REBELO, A.

FACULTY OF SPORT, UNIVERSITY OF PORTO

Introduction: Soccer player must be able to perform more than 50 matches over competitive seasons of around 11 months. This high number of competitions in addition to systematic training may impose considerable physiological strain and fatigue to soccer players possibly affecting physical performance over the season. However, the variation of a large group of physical fitness and functional parameters of professional soccer players throughout the entire season has never been assessed, being the purpose of this study.

Methods: Twenty-two Portuguese elite professional soccer players were evaluated in four occasions throughout the season [prior pre-season (PPS), end pre-season (EPS), mid-season (MID) and end-of-season (EOS)] for counter-movement jump (CMJ), sprint (5 and 30m) agility (T-test), maximal concentric isokinetic knee extensor (KE) and flexor (KF) strength (90°s-1), and intermittent endurance performance (YYIET2; no YYIET2 data were collected in MID due to the Club match commitments).

Results: Improvements in 30m sprint test were observed in MID vs. EPS ($p<0.01$), whereas no change occurred in 5m. CMJ results were higher in EPS vs. PPS, MID and EOS ($p<0.05$). The performance in T-test improved ($p<0.01$) in MID and EOS vs. PPS and EPS. No significant changes were found in KE, KF and bilateral leg strength differences (BD) along the season. However, the dominant leg hamstring/quadriceps ratio (H/Q-DL) increased ($p<0.05$) from MID to PPS. The YYIETL2 performance was higher in EPS ($p<0.01$) and EOS ($p<0.05$) than in PPS and decreased from EPS to EOS ($p<0.05$).

Discussion: Our results suggest that sprint performance is considerable stable throughout the season. Variations in CMJ performance are in accordance with Clark et al. (2008) but not with Malliou et al. (2003). With the exception of H/Q-DL ratio, players maintain the same levels of KE, KF and BD throughout the season. The increased agility in MID and EOS might be due to possible improvements in soccer-specific coordination levels, allowing an improved ability to stop, start and turn rapidly. The increments in YYIET2 observed in competitive period may be related to improvements in players' endurance-related physiological features as aerobic power (Mohr et al., 2002) and anaerobic threshold (Clark et al., 2008), as well as to the increased ability to repeatedly perform eccentric muscular actions. The decrements in YYIET2 performance from EOS to EPS may be linked with the specificity of competition schedule (eg. high number of games in the second half of season), that is, with the reduction in the time devoted to fitness training and also to the development of chronic fatigue.

INDUCED INCREASE OF SYSTEM IMMANENT VARIABILITY THROUGH AN ELASTIC CORD TECHNIQUE TRAINING DEVICE AND A PRACTICAL APPLICATION

HAUDUM, A., BIRKLBAUER, J., KRÖLL, J., SCHWAB, R., MÜLLER, E.

CHRISTIAN DOPPLER LABORATORY 'BIOMECHANICS IN SKIING', UNIVERSITY OF SALZBURG

In motor learning a leading aspect has been on the contentious issue whether movement variability is dominantly attributable to measurement error (Van Emmerik & Van Wegen 2002) or whether it is a system inherent necessity to flexibly adapt to changing environment. Ever since Kelso's coordination dynamics theory (1995) and Schöllhorn's practical application of various forms of variable practice (2000) movement variability is seen as an inevitable and intrinsic feature for motor learning. According to Bernstein (1967) movement outcome is the result of an equivocal relationship between forces generated by muscle contraction and so called reactive phenomena (gravitation, inertia, forces stored in muscle-tendon unit). Hence, if variability of non-muscular genesis is a determinant in movement outcome changes in reactive phenomena should be increased to develop an interpolation ability to adequately adapt to new situations, i.e. stability at one point that relies on the freedom of others to vary. This demand could be put into practice with elastic cords fastened between joints acting as constraints to increase the degrees of freedom and consequently skill related movement variability within the optimal range.

In two experiments we investigated the effect of elastic cords in a complex closed skill under laboratory conditions and in an open sport skill under training conditions. In the latter one variability was further increased by purely altering cord applications.

In the first experiment variability in muscle activity during treadmill running increased with the elastic cords between 39 and 119 % (2 (running condition) X 7 (block) ANOVA: eta2=.55-.70; p<.09), whereas stride duration, a more macroscopic parameter, increased with 21 % (eta2=.65; p<.03). In the second experiment, two groups practiced the smash in volleyball for 18 sessions, one group with, the other without various elastic cord applications. Results unveiled a significant advantage for the cord group in variable situations (2 (group) X 2 (time) ANOVA: eta2=.36; p=.03) whereas constant situations did not reveal similar results (eta2=.03; p=.58).

Data demonstrated an increase of muscle and movement variability through constraints in form of elastic cords. Furthermore, different cord applications led to a superior learning effect, especially in variable situations, what in fact coincide with the real sport situation. In constant task conditions the combination of the subject's inherent variability and task variability probably exceeded the optimal amount of movement variability. Therefore it remains an open research issue to find the optimal level of variability in relation to the subject's individual properties to enhance motor learning.

RESPONSE ACCURACY AND VISUAL SCAN PATTERNS IN OFFSIDE DECISION MAKING

CATTEEUW, P., HELSEN, W., GILIS, B., WAGEMANS, J.

KATHOLIEKE UNIVERSITEIT LEUVEN

Introduction: The aim of this study was to examine the visual scan patterns of association football assistant referees in offside decision making. Oudejans et al. (2000) first explained errors in offside decision making by the optical error hypothesis, i.e. bad positioning of the assistant referees in relation to the offside line results in an incorrect viewing angle and, hence, incorrect decisions. Baldo et al. (2002) and Helsen et al. (2006), however, discussed the flash-lag hypothesis as a relevant explanation of errors in offside judgements. A third explanation came from Belda Maruenda (2004) and Sanabria et al. (1998). They hypothesized that errors in judging offside were due to the time taken to shift gaze from the player passing the ball to the player receiving the ball, implying a time delay. In this study, international and national assistant referees were compared for response accuracy and visual scan patterns when judging offside situations in computer animations and video simulations.

Methods: Five international and five national assistant referees judged computer animations and video simulations of potential offside situations. The visual scan pattern was recorded with a Tobii T120 Eye Tracker. Mann-Whitney U-Tests were used to study the differences in response accuracy and eye movement data with respect to the expertise levels.

Results: The international assistant referees (78.3% computer animations; 83.5% video simulations) judged the potential offside situations significantly better than their national counterparts (61.3% computer animations; 74.6% video simulations) ($p < 0.05$). The national assistant referees showed also a bias towards flag errors. No significant differences were found in the scan patterns (number of fixations and mean fixation duration) of both groups. All assistant referees fixated the offside line before, during and after the precise moment the pass was given.

Discussion: The results of this study provide a better understanding on the potential causes of incorrect offside decisions. International assistant referees were more accurate when judging offside situations. In line with the flash-lag hypothesis as proposed by Baldo et al. (2002) and Helsen et al. (2006), the national assistant referees showed a bias towards flag errors. However, international and national assistant referees employed the same visual scan patterns and showed no shift of gaze. Probably the international assistant referees found a better way to deal with the flash-lag effect.

A NEW METHOD FOR TMS MAPPING

WILLERSLEV-OLSEN, M., GREY, M.J.

UNIVERSITY OF COPENHAGEN

Introduction: The ability to assess cortical plasticity is important in sport science and neurorehabilitation studies. Transcranial Magnetic Stimulation (TMS) may be used to map the representation of muscles in the motor cortex and, therefore, to assess training-induced

changes in cortical representation. The traditional TMS mapping technique is far too time-consuming to be used in most training studies. However, the advent of real-time frameless stereotaxy, which improves the accuracy and repeatability of coil placement/orientation, can be used to make this possible. Here, we describe a modification of the traditional TMS mapping technique that takes advantage of real-time frameless stereotaxy to reduce the number of stimuli required to produce a reliable cortical excitability map.

Methods: Subjects were seated with the right arm supported and the wrist pronated. Surface electromyography was used to record motor evoked potentials (MEPs) in first dorsal interosseous (FDI) while the subjects held a small (~5% maximum) voluntary contraction. TMS was delivered at 0.8 Hz with a MagStim Rapid stimulator and a batwing design coil. The coil was positioned within an 8×8cm grid approximately centered over the hand area of the motor cortex. Stimulation intensity was set to 120% of the active FDI motor threshold when positioned at the location with the greatest MEP (hotspot). Coil position and orientation were monitored in real-time with frameless stereotaxy. For each stimulus, spatial coordinates and the MEP were recorded for offline analysis. In a conventional protocol, 3 MEPs were elicited at each of 64 points within the grid (192 stimuli). In the second protocol, 192 stimuli were elicited at random locations within the grid. The maps were compared with a correlation analysis using $p<0.05$.

Results: The two protocols produced similar maps (mean correlation coefficient $r = 0.8\pm0.1$). To determine the minimum number of stimuli needed to produce a reliable map with the random protocol, correlation coefficients were calculated between the conventional and random maps using successively fewer stimuli from the random protocol. Correlation coefficients began to exceed the 95% confidence interval of the traditional map when the random data set was reduced to the first 35±25 stimuli.

Conclusion

We have demonstrated that reliable maps can be produced with as few as 35 stimuli. At twice the standard deviation observed here (i.e. 85 stimuli), a reliable map can be recorded in as short as 106 seconds with 0.8 Hz stimulation. This method significantly minimises assessment time and will provide better temporal resolution of excitability changes. Our new method may be used to reliably assess motor learning tasks in sport science and neurorehabilitation studies where short acquisition time is essential.

INTER-LIMB COORDINATION, STRENGTH AND POWER IN SOCCER PLAYERS ACROSS THE LIFESPAN

CORTIS, C., TESSITORE, A., PESCE, C., CAPRANICA, L., FIGURA, F.

UNIVERSITY OF MOLISE; UNIVERSITY OF ROME

Introduction: High level of strength and power of young, adult and older soccer players have been widely reported. However, there is a lack of information on coordination, which is crucial for a successful performance. Thus, this study aimed to verify whether a chronic participation in soccer training has a beneficial effect for the improvement and the maintenance of inter-limb coordination performance across the lifespan and whether coordination is moderated by strength and power performances.

Methods: Twenty young (12 ± 1 years), 21 adult (26 ± 5 years), and 16 old (59 ± 11 years) male soccer players were paired to co-aged sedentary individuals and administered strength (handgrip), power (countermovement jump, CMJ), and in-phase (IP) and anti-phase (AP) coordination (i.e., hand and foot synchronized flexions and extensions at 80, 120, and 180 bpm) tests. A 3 (age) x 2 (activity) ANOVA was applied ($p<0.05$). A hierarchical model was used for inter-limb coordination, CMJ and handgrip parameters.

Results: Regardless of age, soccer players always showed better ($p<0.0001$) performances (handgrip: 383 ± 140 N; CMJ: 28.3 ± 8.7 cm; IP: 55.2 ± 12.9 s; AP: 31.8 ± 25.0 s) than sedentary individuals (handgrip: 313 ± 124 N; CMJ: 21.0 ± 9.4 cm; IP: 46.7 ± 20.2 s; AP: 21.1 ± 23.9 s). A hierarchical model ($p<0.0001$) emerged for CMJ, explaining 30% and 26% of the variance for IP and AP, respectively. In contrast, handgrip did not provide increments in the explained variance.

Discussion/Conclusions

Results indicate that chronic soccer training is beneficial to develop strength, CMJ and inter-limb synchronization capabilities in children, to reach higher levels of proficiency in adults, and to maintain performance in old individuals. The predicted role of CMJ on inter-limb coordination indicates that timing in neuromuscular activation is central for both jump (Bobbert and Van Soest, 2001) and inter-limb coordinative performances (Salesse et al., 2005). Thus, soccer coaches are strongly recommended to modulate complex motor behaviours with increasing velocity of execution to induce higher executive function and attentional control during technical and tactical drills under time pressure.

THE EFFECT OF HEAVY STRENGTH TRAINING ON MUSCLE ADAPTATIONS AND PERFORMANCE IN ELITE CROSS-COUNTRY SKIERS

LOSNEGARD, T., MIKKELSEN, K., RØNNESTAD, B.R., HALLÉN, J., RUD, B., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCE, OSLO AND LILLEHAMMER UNIVERSITY COLLEGE, LILLEHAMMER, NORWAY

Introduction: Cross-country skiing is a typical endurance sport with high reliance on maximal aerobic power. However, the introduction of sprint skiing and mass start has increased the importance of other physiological factors affecting top speed on skies, such as muscular strength and the ability to generate high power. A good correlation has been reported between maximal power output measured in a 4RM rollerboard test and sprint skiing tests in cross-country skiing (Stöggl et al 2007). In addition to have a potential role on maximal power generation and top speed on skies, heavy strength training may also reduce the energy cost of skiing and thereby also affect endurance performance (Hoff et al 1999, Østerås et al 2002).

Method: Eleven males (18-26 yr, VO2max; 68.3 ± 4.8 ml•kg-1•min-1) and eight females (18-27 yr, VO2max; 59.3 ± 2.9 ml•kg-1•min-1) were assigned to a strength training group (STR) (n=9) and a control group (CON) (n=10). In addition to their regular training, STR performed heavy strength training twice a week, for 12 weeks (3-4 x 4-10RM sets in three exercises for upper-body muscles and one exercise for legs).

Results: One repetition maximum (1RM) improved in STR both in sitting pull-down (19 %) and half squat 12 % ($p<0.01$), while no changes was observed in CON. Jump height was 6.2% reduced in CON ($p<0.05$), while no change was observed in STR. A small increase in cross sectional area (CSA) were found in m. triceps brachii for both STR and CON ($p<0.05$), with no change in m. quadriceps CSA. VO2max in ski-skating increased 7% in STR ($p<0.01$), but was unchanged in running. Work economy, evaluated from VO2 during submaximal rollerskiing was unchanged and rollerski skating time-trial performance (~5 min) improved similarly in both groups. A 100 meter sprint skiing test showed no significant changes in performance between groups. Correlation analyses from baseline (n=25) showed a strong correlation between 1RM sitting pull-down and time-trial performance and 1RM half squat and 100 meter rollerski skating performance ($p<0.01$). However, we were not able to observe any significant correlation between changes in 1RM and changes in any of the performance tests.

Discussion: A 12-week period of heavy strength training improved maximal strength in leg and upper body muscles, but had little effect on muscle cross sectional area in thigh muscles. In addition, heavy strength training added to regular endurance training improved VO2max during skating. However, we were not able to observe any statistically significant beneficial effects in time-trial performance on rollerskies.

THE EFFECT OF HEAVY STRENGTH TRAINING ON PERFORMANCE AND MUSCLE ADAPTATIONS IN ELITE NORDIC COMBINED ATHLETES

KOJEDAL, Ø., KVAMME, B., LOSNEGARD, T., RØNNESTAD, B.R., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCE

Introduction: Performance in Nordic combined is dependent on both endurance performance in cross country skiing and the ability to generate maximum power during take-off in ski jumping. Heavy strength training on leg muscles has the ability to improve power in leg extensors, but it is uncertain how a large volume of endurance training may influence this adaptation. Furthermore, strength training of upper body muscles may also improve performance in cross country skiing (Hoff et al., 2002). However, the effect of heavy strength training has not been investigated in Nordic combined athletes. Thus, the aim of this study was to investigate the effect of adding heavy strength training to normal training in elite Nordic combined athletes.

Methods: 17 male Nordic combined athletes (16-26 yrs, VO2max: 66.2±1.2 ml∙kg-1∙min-1) were assigned to a strength training group (STR, n=8) and a control group (CON, n=9). STR performed strength training twice a week, for 12 weeks with 3-5 x 10-3 repetition maximum (RM) training loads in two exercises for upper-body (seated pull-down and standing double poling) and one exercise for the lower-body (deep squat) as a supplement to their regular training. CON maintained regular training without heavy strength training. Measurements of muscle thickness, 1RM, roller ski performance (7.5 km time trial), work economy and VO2max during treadmill roller skiing and vertical jump-height were performed before and after the training intervention.

Results: STR increased muscle thickness of m. vastus lateralis (7.1±3.0%) while no change was observed in CON (-2.2±2.5%). STR improved 1RM in both seated pull-down and deep squat (23±6% and 12±4% respectively), while no change was observed in CON. Vertical jump-height improved in STR (8.8±4.9%), while no change was observed in CON. The change in relative strength in deep squat was correlated with changes in vertical jump–height (r=0.59). Maximal aerobic power in ski skating, time-trial roller ski performance, skiing economy, and body weight remained unchanged from before to after intervention in both groups.

Discussion: As expected, the 12-week period of heavy strength training improved 1RM deep squat and increased vertical jumping height (McBride et al., 2002). On the other hand, we did not observe any improvements in maximal aerobic power or working economy during ski skating. The increase in muscle thickness did not lead to a subsequent increase in body weight. Altogether; strength training may improve total performance in Nordic combined by improving the athletes' ability to mobilize maximal power during ski jumping without negatively affecting cross country skiing performance.

TECHNICAL AND TACTICAL ANALYSIS OF YOUTH TAEKWONDO PERFORMANCE

CASOLINO, E., CHIODO, S., TESSITORE, A., LUPO, C., CORTIS, C., CAPRANICA, L.

UNIVERSITY OF ROME

Technical and tactical analysis of youth Taekwondo performance

Casolino E.1, Chiodo S.2, 3, Tessitore A.1, Lupo C.1, Cortis C.1, 4, and Capranica L.1

1 Department of Human Movement and Sport Sciences, University of Rome Foro Italico, Italy

2 School of Medicine, University Magna Grecia of Catanzaro, Italy

3 Italian Taekwondo Federation, Rome, Italy

4 Department of Health Sciences, University of Molise, Campobasso, Italy

Introduction: Several studies focused on the psychological and physiological aspects of elite Taekwondo athletes, while little information is present regarding the technical and tactical aspects of the match (Kazemi et al., 2005, 2006). Considering that athletes start training and competing around 10 years of age, an area that needs attention is the study of youth performance. Therefore, this study aimed to

analyze the technical aspects of young athletes competing in the Italian Youth (i.e., Cadetti A) Taekwondo Championships in relation to gender, age, and match outcome.

Methods: Sixty youth taekwondo athletes (age range: 10-12 yr) participated in the study according to their weight category (ranging from -24 kg to +59 kg). Thirty-seven matches (three 1-min rounds, with 1 minute rest in between) were recorded for further match analysis. Sixteen kicking techniques, equally divided in offensive and defensive actions, were considered. A 3 (round: first vs second vs third) x 2 (match outcome: victory vs defeat) x 2 (gender: female vs male) ANOVA for repeated measures was applied to verify differences ($p<0.05$) in the frequency of occurrence of the kicks with relative PLSD post-hoc.

Results: Regardless of gender, the offensive techniques occurred more frequently (91.5%, 14±8) than defensive ones (8.5%, 1±2) ($F(1, 70) = 210.1$; $p<0.0001$). Regarding gender, the number of techniques approached the significance ($F(1, 70) = 3.93$; $p = 0.0531$), with a higher occurrence for female (3±4) than male (2±3) athletes. Moreover, females attack more and defend less than males ($p=0.0054$).

In relation to match outcome ($F(1, 70) = 18.43$; $p<0.0001$), the number of technique was higher for winners (3±4) than losers (2±2). Regarding the rounds ($F(2, 140) = 10.07$; $p=0.0004$), differences between offensive techniques emerged only between the first (6±4) and third (4±3) while differences between the second (5±3) and third round approached significance ($p=0.064$). No difference was found for the defensive techniques among the three rounds.

Discussion/Conclusion

The lower frequency of defensive techniques with respect to the offensive ones indicates that young taekwondo athletes did not completely develop this capability. Thus, coaches are urged to stress defensive drills during their trainings.

REGIONAL AND NATIONAL COMPETITION OF YOUNG PROMOTIONAL GYMNASTIC: A LONGITUDINAL STUDY

COMOTTO, S., DE PERO, R., CAPRANICA, L., PIACENTINI, M.F.

UNIVERSITY OF ROME

Introduction: Amateur gymnastics includes competitions with easy technical programmes and provide a massive participation of both young and master athletes. Anxiety and self-efficacy are the psychological factors most commonly linked to motor performance during elite gymnastics. Best performance is correlated with a low level of anxiety and a high level of self-efficacy (Cartoni et al, 2005). Amateur gymnastic however has never been investigated therefore the aim of the present study was to investigate the correlation between anxiety, self-efficacy and performance during Regional (RC) and National (NC) competitions in young gymnasts.

Methods: Fourteen young female gymnasts, (mean starting age 13 ± 2) were administered State-Trait Anxiety Inventory form Y (STAY-Y) (Spielberger, 1983) with a scale ranging from 20 to 80 points and the Self-efficacy for Physical Abilities (SEM-S) (Bortoli, Robazza, 1996) with a scale ranging from 10 to 50 points. The Trait anxiety questionnaire was administered in a non competitive period. The State anxiety and the self-efficacy questionnaires were administered after the warm-up session of the RC and NC throughout a 2 year data collection period. The Friedmans Test ANOVA for repeated measures was used to examine statistical differences between State-Trait Anxiety responses, self-efficacy and performance ($p<0.05$). A Polynomial correlation was used between performance, State anxiety and self-efficacy.

Results: No significant difference was found for state anxiety and penalties obtained in competition. Throughout the two year period anxiety (RC: 2007 M=46 ± 13 vs 2008 M=45 ± 10; NC: 2007 M=50 ± 14 vs 2008 M=46 ± 12) and penalty during competition decreased (RC: 2007 M=0.69 ± 0.27 vs 2008 M=0.66 ± 0.27; NC: 2007 M=1.08 ± 0.42 vs 2008 M=0.84 ± 0.28). During RC anxiety decreased by 2% and during NC by 7%. In the RC penalties decreased by 4% and in NC by 23%. No correlation was found between state anxiety and performance. A negative correlation was found between anxiety and self-efficacy (Pearson's Correlation: Regional 2007=-0.913, 2008=-0.786; National 2007=-0.853, 2008=-0.869).

Discussion/Conclusion

The improvement in performance (decreased penalties) and the decrease in anxiety observed throughout the 2 year period can be attributed to the increased experience of the young gymnasts and by the fact that the exercise routine remained the same throughout the 2 year period. As already confirmed in previous studies, the athletes showed higher anxiety levels and penalties during the NC compared to the RC (Cottyn, et al., 2006).

VAULT RUN-UP CHARACTERISTICS AND THEIR INFLUENCE ON HIGH LEVEL FEMALE GYMNASTICS PERFORMANCE.

MASSARO, A., EMERENZIANI, G.P., BROCCATELLI, M., BALDARI, C., GUIDETTI, L.

UNIVERSITY OF ROME

Introduction: Vault is one of the four apparatus of the female gymnastics. Despite a large studies about the biomechanical aspect of the Vault skills, there are currently a paucity of data regarding the effectiveness of Vault run-up on exercise successful evaluated by judge score (Sands and McNeal, 1995, Krug et al., 1998). The aim of this study was to analyze the effects of vault run up parameters on quality vaulting performance.

Methods: Sixteen female gymnasts (age: 18±3 yrs; height: 154.1±7.3 cm; weight: 44.5±6.1 kg) of four different national teams (Italy, Brazil, Romania and Belarus) performed vault exercise during international competition (Mediterraneo Gym Cup). All the gymnasts performed vaults of Yourchenko type, which is characterized by a round off before the springboard impact. During vault performance contact time (CT), flight time (FT), step length (SL), step height (SH), run-up velocity (RV) and acceleration (RA) were assessed step by step using Optojump system (Microgate, Bolzano, Italy) along runway mat. Moreover judges' score were recorded. Judges' score is made up of A and B score. A score corresponds to the skill difficult, and B score corresponds to the judges' deductions. The final score results from the difference between A and B score.

Results: Correlation analysis was used to assess the relationship between all the run-up variables and judges' score. Last run-up step CT (0.12±0.01 s) and hurdle CT (0.11±0.01 s) were significantly ($p<0.05$) related to B (9.0±2.7 points; r= -0.515 and r= -0.512, respectively) and final scores (14.4±7.0 points; r= -0.5 and r= -0.512, respectively).

No significant correlations were found between all the other variables and judges' score.

Discussion: Our results, according with literature, showed that run-up velocity did not appear correlated with vaulting performance (Sands and Cheetham, 1986). This could be due to the gymnastics' focus on the springboard approach during the run-up, since before the springboard impact they have to be focused also on the round off. Our main finding was that higher judges' final scores were related to shorter contact time of the final run-up step and of the hurdle. These results showed how the vault run-up is characterized also by technical variables and not only by kinematics variables. Therefore future research must focus on last run-up step and on hurdle characteristics rather than on run-up speed.

COMPARISON OF VERTICAL JUMPING PERFORMANCE AMONG YOUNG SEDENTARY SUBJECTS, BASKETBALL AND VOLLEYBALL PLAYERS

BATTAGLIA, G., BELLAFIORE, M., BIANCO, A., CARAMAZZA, G., PAOLI, A., FARINA, F., PALMA, A.

UNIVERSITY OF PALERMO

Introduction: The ability to jump high is considered important in a number of sports. It is commonly accepted that the use of the arms increases jump height (I). In particular, in some sport situations such as basketball and volleyball the ability to utilize arm swing is fundamental in order that players may reach the maximum performance. Instead, sedentary subjects are not usually able to utilize efficiently upper-limb motion compare to active people during vertical jumping performance.

The purpose of this study was to examine flight time (sec.) [Ft], jump height (cm) [Jh] during vertical jumping by countermovement [CMJ] with and without arm swing in young, sedentary subjects and basketball and volleyball players from similar category.

Methods: Thirty one young girls, 11 sedentary subjects [SS] (age: 15+/-1 years, height: 159.81+/-3.48 cm, weight: 53.90+/-5.62 kg, BMI: 21.10+/-2.09); 10 basketball players (age: 15+/-1 years, height: 160+/-4.44 cm, weight: 57.9+/-6.98 kg, BMI: 22.67+/-3.13) and 10 volleyball players (age: 16+/-1 years, height: 160.6+/-4.59 cm, weight: 57.2+/- 5.47 kg, BMI: 22.17+/-1.87) performed 2 jumping movements: CMJ with hands on hips (CMJ-HH) and CMJ with arm swing (CMJ-AS) that were analyzed by Optojump system (Microgate, Bolzano, Italy). The optical acquisition system allowed the measurement of contact and flight times during a jump to a precision of 1/1000s (II).

Results: Flight time (sec.) [Ft] and jump height (cm) [Jh] data obtained by both tests were higher in players than sedentary subjects. In CMJ-HH volleyball players had higher Ft and Jh than basketball players. In CMJ-AS the use of the arms was found to increase vertical jumping in all three groups. In particular, players showed a better vertical jumping performance than sedentary subjects because present an increased ability to utilize of arm swing. Moreover, Ft and Jh were higher in volleyball players than basketball players during CMJ-AS.

Discussion: A higher muscle power of lower limbs, motor coordination and upper body strength could be the cause of the better performance of players than sedentary subjects. Moreover, higher Ft and Jh in volleyballers than basketballers during CMJ-AS could be due to the different performance model of these sport situations. The volleyballers might develop a higher ability of muscle power than basketballers because during volleyball game they perform numerous vertical jumps in a smaller place than game ground of basketballers.

DEVELOPMENT OF LONG JUMP TECHNIQUE IN YOUNG ATHLETES

MAMPIERI, L., CAMOMILLA, V., BERGAMINI, E., CAPRANICA, L., PIACENTINI, M.F.

UNIVERSITY OF ROME

Development of long jump technique in young athletes

Luca Mampieri, Valentina Camomilla, Elena Bergamini, Laura Capranica, Maria Francesca Piacentini

University of Rome-Foro Italico

Long jump is one of the most natural track and field disciplines but not the most simple. Long jump is divided in four fundamental phases: run-up, take-off, flight and landing. Run-up and take-off are the two phases that will determine the success in this event. Results from previous studies showed that take-off execution can discriminate between elite and non elite athletes (Chen-Fu and Chen-Shou 2007). Therefore, the purpose of the present study was to discriminate between different performance levels by measuring technical and cinematic parameters.

METHODS: Ten long jump and triple jump athletes were divided in two subgroups: specialized, S (age 17,6 ± 2,41, personal best 5,92 ± 1,07 m), and non specialized, NS (age 13,4 ± 1,1, personal best 4,59 ± 0,58 m) and tested during a training session. The following long-jump parameters were obtained through videoanalysis (Dartfish TeamPro): horizontal and vertical velocity and ankle angle at take-off and touch-down, knee flexion of the take-off leg at take-off, time on board, and differences between the last two steps (Hay 1992). Force related tests were performed on a force platform: counter movement jump (CMJ), drop jump (DJ), and standing long jump (SLJ). Differences between the long jump parameters of the two groups were analysed with unpaired student t test and a Pearson correlation was performed between tests and long jump parameters.

RESULTS: No significant differences were observed in performance between S and NS, however S jumped 12,76 % more. The length of the last two steps were significantly different between S and NS (S penultimate and last step 2,29 ± 0,21 and 2,03 ± 0,1 respectively; NS penultimate and last step 1,85 ± 0,08 and 1,77 ± 0,13 respectively). SLJ was significantly correlated with CMJ (r = 0,95) and performance measured in competition (r = 0,98) in S but not in NS.

DISCUSSION: The results of the present study demonstrate that technical abilities were significantly different between the two groups while the results of specific tests (CMJ, DJ, SLJ) did not differ. The NS still train and compete in different disciplines and therefore have

good strength and speed capacities but lack in technical precision. In order to improve as well, and try to reach the elite, they should concentrate on one preferred discipline only.

AGE AND GENDER SPECIFIC PHYSIOLOGICAL CHARACTERISTICS OF TYROLEAN JUDOKAS

POCECCO, E., BURTSCHER, M.

UNIVERSITY OF INNSBRUCK

Introduction: In judo, besides technical skills and tactical strategies, fitness is also indispensable for a successful performance. Few studies have examined physiological profiles of judo athletes and there are no laboratory tests lasting the duration of a judo competition which assess maximum arm and leg performance.

The aim of this study was to describe age and gender dependent maximum arm and leg performance of judo athletes, derived from laboratory tests, which are similar in duration to a judo competition (5 min).

Methods: The test group consisted of 7 juvenile female, F (1990-93) and 30 male (M) judokas: 7 children, C (1992-94), 10 juveniles, J1 (1990-91), 4 juveniles, J2 (1986-88) and 7 adults, A (1959-85), of different competitive level.

The test session took place in June 2006. Anthropometric measurements included stature, body mass and body composition (bio-impedentiometry). Physiological parameters at rest were measured. During and immediately after a ramp test (5W-increments) on an arm-crank ergometer (increments in W = ½ body mass/min) and on a cycle ergometer (increments in W = body mass/min) maximum power (Pmax), heart rate, ventilatoric parameters (i.e. VO2peak), perceived exertion and blood lactate 3 min post exercise (LA) were assessed.

Statistics: MANOVA and Pearson-correlations using SPSS.

Results: Upper body (UB): Pmax (W/kg): C 2.37, J1 2.60, J2 2.70, A 2.57, F 2.46; VO2peak (ml/min/kg): C 37.3, J1 39.2, J2 35.3, A 30.9, F 29.8; LA (mmol/l): C 7.8, J1 10.4, J2 11.8, A 11.4, F 6.5. Lower body (LB): Pmax (W/kg): C 5.28, J1 5.36, J2 5.76, A 5.38, F 4.81; VO2peak (ml/min/kg): C 52.6, J1 51.2, J2 50.0, A 45.0, F 45.3; LA (mmol/l): C 7.9, J1 11.1, J2 12.0, A 12.0, F 9.1.

Concerning UB, women's Pmax/kg was lower than values of J1, J2 and A. J1 had a higher arms' VO2peak/kg than A and F. C and F had lower values of LA after cranking compared to the other groups. Concerning LB, no significant differences were noticed. VO2peak/kg during both tests decreased and LA after cranking rose with increasing age among M.

Discussion: All these results confirm data from our laboratory (3) and literature. Gender differences are in accordance with scientific knowledge on muscle strength and power and with research on judokas (2, 3). Also the shown gender and age differences in VO2peak and LA are reported in the literature, which identifies the age (14-17 years) in which the highest relative VO2max values are reached (1). These trends probably reflect the lower volume and efficacy of strength training among young athletes and women.

LOAD ANALYSIS OF KARATE KATA SITUATIONAL TRAINING

BOK, D., JUKIC, I., VUCETIC, V.

FACULTY OF KINESIOLOGY, UNIVERSITY OF ZAGREB

INTRODUCTION: Kata is a karate discipline comprised of basic karate techniques presenting the offensive and the defensive actions. As kata is performed identically on training and competition, it is relatively easy to assess actual competition load measuring performances during situational training. The goal of the research was to establish the level of intensity of 5 consecutive kata (Jion, KD, KS, GSS, Unsu) performances with 5 min rest periods.

METHODS: A member of Croatian national kata team (29 yrs;179 cm;91 kg) performed incremental treadmill test (0,5 km/h speed increase per minute, 1,5% grade) for determination of VO2max and HRmax (50.8 mlO2/kg/min;191 bpm) and anaerobic threshold (AnT -46.4 mlO2/kg/min;186 bpm). The level of intensity of 5 consecutive kata was measured through: heart rate (HR), blood lactate (LA; Lactate Scout, USA) and oxygen uptake (VO2; COSMED, Quark K4, Italy).

RESULTS: The duration of each kata was 102s in average. HR before each 5 performance was 137, 150, 150, 124 and 137 bpm (73.1% HRmax,75.1% HRAnT in avr) and after the kata performance 196, 197, 188, 193 and 189 bpm (100.1% HRmax,103.6% HRAnT in avr). VO2 before each kata was 14.7, 13.4, 19.9, 12.5 and 9.3 mlO2/kg/min (27.5% VO2max,30.1% VO2AnT in avr) and after the performance 39.1, 41.6, 33.7, 29.5 and 28.2 mlO2/kg/min (67.7% VO2max,73.8 VO2AnT in avr). LA before each kata was 1.2, 12.6, 14.2, 14.3 and 16.8 mmol/l; after kata 5.7, 13.2, 14.4, 14.4 and 13.0 mmol/l and 3 min after kata 11.3, 13.4, 14.0, 13.9 and 13.9 mmol/l.

DISCUSSION: HR after the kata performance indicates extremely high intensity of activity which goes even above the HRmax estimated on the treadmill test. The HRpeak was lower in the last 3 katas, which can be attributed to the more economical performances and accumulated fatigue. Analysing the VO2 after each performance, which is always lower than after the previous one, it can be concluded that anaerobic metabolism is increasing with each performance. It also indicates that 5 min break is not enough for complete recovery. This has also been supported by values of LA. Each consecutive kata has been performed with higher LA which also indicates insufficient recovery period and glicolitic character of the activity.

CONCLUSION: In comparison to already reported results, this case study presents higher physiological demands of kata performance. It is likely due to the highly trained subject examined and higher level of kata performances. Kata performance can be considered as high intensity anaerobic activity with high lactate tolerance demands of an athlete. Situational training (5 katas with 5 min recovery) can be considered as extremely demanding system in which the anaerobic metabolism is increasing with each consecutive kata and the rest period is insufficient for full recovery.

THE PHYSIOLOGY OF WORLD CLASS SPRINT SKIERS

SANDBAKK, Ø., LEIRDAL, S., HOLMBERG, H.C., ETTEMA, G.

1.HUMAN MOVEMENT SCIENCE PROGRAMME, NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM, NORWAY, 2.OLYMPIATOPPEN MIDT-NORGE, TRONDHEIM, NORWAY, 3.SWEDISH WINTER SPORTS RESEARCH CENTRE, DEPARTMEN

Introduction: During sprint competitions in cross-country skiing, athletes perform four separate races of 1200-1800m (2 to 4 min), starting with a time-trial qualification race, and thereafter heats based on a knock-out system. In order to better understand world class sprint performance, the present study investigated the differences between world class and national class sprint skiers with regard to their physiological characteristics. Methods: Eight world class (26.1±3.5 yr, 184.8±5.6 cm, 83.3±6.4 kg, sprint FIS-points 22.2±12) and eight national class (24.5±2.3 yr, 186.4±6.6cm, 82.8±6.6 kg, sprint FIS-points 100.6±45.6) sprint skiers participated in the study. They performed three standardized tests using the freestyle V-2 technique while roller skiing on a treadmill: 1) an absolute submaximal velocity test, 2) an incremental peak aerobic capacity (VO2peak) test, and 3) an incremental treadmill velocity test, leading to a maximal obtainable speed after 60-90s (Vmax). Moreover, all the subjects performed 30m acceleration and 30m maximal speed tests in the skating V-2 technique outdoors on an asphalt road. Additionally, the amount of training was quantified for different intensity zones, from low intensity endurance training to strength and speed training, according to training logbook entries. Comparisons between groups were made using the t-test procedure. Results: World class athletes showed significantly lower blood lactate levels, respiratory exchange ratio and heart rate, as well as better gross efficiency, at the submaximal velocity (all $P<0.05$). Furthermore, they had higher VO2peak, speed at VO2peak, Vmax-speed, and faster lactate clearance after the Vmax (all $P<0.05$). No differences in acceleration, maximal speed and peak lactate levels were found. World class athletes performed more endurance training and speed training ($P<0.05$). Discussion: World class sprint skiers are similar to national class sprint skiers as regards maximal speed and acceleration. However, they are superior in aerobic capacity, efficiency and lactate clearance. Among sprint skiers, we hypothesize that a certain level of speed is needed, however, the aerobic characteristics are what differentiates different performance levels. It is suggested that national class athletes with already high speed capacities should increase their emphasis on endurance training to further improve sprint performance.

MANIPULATION OF TRAINING INTENSITY DISTRIBUTION IN DISTANCE RUNNERS AND ITS IMPACT ON ENDURANCE PERFORMANCE: A CROSS-OVER STUDY

HEYER, L., BREIL, F., LEHMANN, A., REICHLIN, L., PRISI, D., VOGT, M.

1. UNIVERSITY OF BERN, 2. UNIVERSITY OF LAUSANNE

Introduction: The training intensity distribution between elite and moderately-trained athletes is different (Seiler & Kjerland, 2006). Untrained or moderately-trained subjects commonly exercise following a "threshold-training" model allocating a high proportion of moderate intensity exercises while (international) elite athletes seem to prefer a "polarized training" distribution tending to minimise trainings between the first (VT1) and second ventilatory threshold (VT2). The purpose of the current crossover designed study was to evaluate the effect of a polarized training distribution on physiological determinants of performance in endurance runners.

Methods: In the first year and after a 12-weeks baseline period, fifteen well-trained recreational runners were randomly assigned for 10 weeks to either polarized training (POL) or a normal training (CON) period. According to a crossover design training groups were switched for the same training duration one year later. During POL the runners performed 70±7% of all endurance sessions in zone 1 (<VT1), 4±5% in zone 2 (between VT1 and VT2) and 26±6% in zone 3 (>VT2), while CON trained 50±18% in zone 1, 26±15% in zone 2 and 24±4% in zone 3. VO2max, maximal running speed, ventilatory thresholds, running economy, respiratory exchange ratio and anaerobic power were measured before the baseline period and each year immediately before and after the intervention period.

Results: VO2max increased significantly for CON (pre: 62.3±6.0; post: 64.9±6.2 ml•min-1•kg-1) but not for POL (pre: 62.1±6.6; post: 63.1±6.2 ml•min-1•kg-1). Maximal running speed, ventilatory thresholds and running economy did not change for POL and CON. Respiratory exchange ratio was significantly decreased at 10km•h-1 (pre: 0.92±0.02; post: 0.90±0.02), at 11.5 km•h-1 (pre: 0.94±0.03; post: 0.91±0.03) and at 13 km•h-1 (pre: 0.96±0.04; post: 0.94±0.03) after POL only. In the anaerobic 30-seconds Wingate tests peak power output (+4.1±4.0%, $p<0.01$) and mean power output (+1.8±2.7%, $p=0.07$) were only increased after POL. Despite unaltered training volume (~5h•week-1), body fat content was significantly higher after POL (pre: 8.6±2.9; post: 9.3±2.9%).

Conclusions: When frequency of high intensity training in zone 3 is fixed at around 25% of total endurance sessions, the relative contribution of low (zone 1) and middle (zone 2) intensity training does not affect maximal endurance performance in well-trained recreational runners. However a polarized training pattern seems to slightly modify substrate selection and improves anaerobic performance. Unlike for elite athletes, a polarized distribution of the training intensity seems not to be preferable for recreational runners performing low to moderate training volumes.

ARE YOU IN THE MOOD FOR MOTIVATION?

WEST, J., CASTLE, P., RHODEN, C.

UNIVERSITY OF WORCESTER

Although motivation has been thoroughly investigated and is still a current research topic, there has been little research concerning the interaction between affect and motivation (Matsumoto and Sanders, 1988). In the hierarchical model of motivation autonomy, competence and relatedness are key underlying factors in motivation within self determination theory; however, these have been found to relate more towards a global or personality form of motivation (Rhodes et al, 2006). At the situational level, the hierarchical model suggests that

motivation is similarly derived and mediated as at the global and contextual levels. It has been suggested that motives are related to emotion, personality and behaviour, consequently underpinning thoughts, emotions and behaviours across the lifespan (Robinson et al, 2005). Thus it seems logical to surmise that at this situational level, motivation is determined to a greater extent by the mood and emotion of the individual at that time (Barnett, 2006).

This study aims to ascertain possible links between mood, emotion and motivation using the Profile of Mood States (POMS), Sports Motivation Scale (SMS) and Sport Emotion Questionnaire (SEQ).

Second year sports students were recruited for this study (n=58). One hour prior to the activity participants were asked to complete an SMS questionnaire with the upcoming activity in mind. Ten minutes prior to participating in the activity participants were asked to complete the pre POMS and SEQ questionnaires. Participants then completed their selected activities for a period of 30 minutes. Immediately after a warm down, participants were asked to complete the post POMS and SEQ to ascertain post mood and emotion. Data was analysed using Pearson product-moment correlation to assess the relationship between motivation, mood and emotion.

Preliminary findings suggest that intrinsic motivation is strongly correlated to positive mood and extrinsic motivation shares a medium relationship strength with positive mood and emotion.

RELATIVE AGE IS ASSOCIATED WITH MALE SOCCER DROPOUT

DELORME, N., BOICHÉ, J., RASPAUD, M.

UNIVERSITY J. FOURIER - GRENOBLE I

Introduction: The purpose of this study is to examine the birthdates distribution of French male soccer players who ceased their participation, so as to test whether the Relative Age Effect (RAE) is related to the dropout behaviour. We hypothesize that young players born late in the competitive year would be over-represented in the dropout sample. Conversely, because of their relative age and its associated advantages, the young players born early in the year should be under-represented in this sample.

Methods : At the end of the 2007-2008 season, the birthdates of the French male players (n = 363,590) licensed during the 2006-2007 season and that had not reiterated their licence during the following season were collected through the database of the French Soccer Federation (FSF). We waited until the end of the 2007-2008 season to collect the data, in order to avoid considering as dropout some players that took their licence while the new season had already begun.

For each of the 7 age categories distinguished by the FSF, the players' birthdates were classified into 4 quarters. As the cut-off date has changed in France, players born before 1982 were classified from Q1 (August-October) to Q4 (May-July), whereas those born in 1982 and after were classified from Q1 (January-March) to Q4 (October-December). Then, a chi square test was carried out to determine whether the observed distribution by quarter significantly differed from the theoretical distribution. The theoretical distribution was calculated from the corresponding population of licensed players, using weighted mean scores.

Results: An over-representation of players born in the last two quarters was found among dropouts, from the less than 9 to the less than 18 age categories, whereas the players born during the first two quarters were under-represented. No significant difference between the theoretical and observed distribution appeared concerning the less than 7 and adult categories.

Discussion: These results confirm that the RAE can act as a sport dropout factor from the less than 9 to the less than 18 age categories. For the players born in Q4, the differences in physical attributes and the subsequent reduced opportunities to play, associated with lowered self-worth perceptions and perceived competence, are likely to lead to higher dropout rates. Concerning the less than 7 category, the absence of effect can be explained by two elements. First of all, in this category, the differences in terms of physical attributes remain modest. Next, it must be outlined that the FSF does not organize official competition for them. Thus these players are less likely to be confronted to situations of failure or inferiority. Finally, a distribution conform to the one observed among the whole population of licensed adult players was observed among adult dropout players. This result is coherent with past studies having shown that RAE gradually declines with age.

MOTIVATION FOR SPORT IN YOUNG ITALIAN COMPETITIVE ATHLETES.

AMICI, S., DE PERO, R., PIACENTINI, M.F., CAPRANICA, L.

UNIVERSITY OF ROME FORO ITALICO

Introduction: The study aimed to investigate the motivation to sport participation of young Italian competitive athletes in relation to gender, age and type of sport participation.

Methods: The Sport Motivation Scale questionnaire (Pelletier et al.1995) was administered to 354 subjects (197 girls and 157 boys) 232 swimmers and 122 gymnasts divided in 2 age groups 9-12 and 13-17 yrs. To test for significance ($p<.05$), a 2(gender) x 2(age) x 2(type of sport) MANOVA was applied with seven subscales of motivation as dependent variables.

Results: A main effect was found for gender (Wilks'Lamba(7,340)=2.6 $p<.05$ np2=.05) with significant effects for External Regulation ($F(7.340)=7.3$ $p<.05$ np2 =.02) with higher values of External Regulation for boys compared to girls (16.3±5.6vs14.2±5.6). A main effect was found for age (Wilks'Lamba(7,340)=5.5 $p<.05$ np2=.10) with significant effects for To Know ($F(7.340)=31.4$ $p<.05$ np2=.08) Stimulation ($F(7.340)=9.8$ $p<.05$ np2=.03) Accomplishment ($F(7,340)= 4.9$ $p<.05$ np2=.01) and Identified Regulation ($F(7.340)=4.6$ $p<.05$ np2 =.01) subscales. The 9-12 yrs showed higher values compared to the 13-17 yrs for To Know (19.6±5.2vs16.7±5.1) Stimulation (20.7±4.9vs9.6±4.7) Accomplishment (20.3±5.0vs19.4±4.8) and Identified Regulation (17.3±5.2vs15.9±4.3). A main effect for type of sport (Wilks'Lambda(7.340)=20.5 $p<.05$ np2=.30) emerged with significant effects for To Know ($F(7.340)=46.0$ $p<.05$ np2=.12) Stimulation ($F(7,340)=7.9$ $p<.05$ np2=.02) Accomplishment ($F(7,340)=32.5$ $p<.05$ np2=.09) Identified Regulation ($F(7.340)=26.2$ $p<.05$ np2=.07) and External Regulation ($F(7.340)=4.0$ $p<.05$ np2=.01) subscales, gymnasts showed higher values than swimmers for To Know (20.6±5.3vs6.9±4.9) Stimulation (21.2±4.6vs19.6±4.9) Accomplishment (22.1±4.7vs18.8±4.7) and lower values than swimmers for Identi-

fied Regulation (14.9±4.9vs17.6±4.6) and External Regulation (14.2±6.0vs15.7±5.4). Interaction gender x age (Wilks'Lamba(7,340)=2.6 p<.05 np2=.05) emerged with significant effects for External Regulation (F(7,340)=8.2 p<.05 np2=.02) subscale, with girls showing lower values of External Regulation compared to boys.

Conclusion/Discussion: Similarly to previous studies regarding motivation and gender, (Pethrick & Weigand 2002) young boys seem to engage in sport to obtain rewards, or avoid negative feedback. Regarding sport type, gymnasts seem to enjoy more their activity (Brustand 1988) and to desire to pursue challenges (Wong & Bridges 1995), while swimmers seems to train to satisfy an external demand and personal development (Fortier et al. 1995). Showing lower values of External Regulation compared to the other age groups, girls older than 13 seem to need less external approval.

ACHIEVEMENT GOALS, SELF-DETERMINATION AND BELIEFS ABOUT THE NATURE AND DETERMINANTS OF SPORT COMPETENCE – A STUDY OF PORTUGUESE FOOTBALLERS

SARMENTO, H., CATITA, L., FONSECA, A.

UNIVERSIDADE DO PORTO

Frequently coaches, players and audience associate the collective and individual performance to different motivational states. In spite of the existence of a significant quantity of studies that examine motivation in the context of physical and leisure activities, very few coincide in contexts of a natural competitiveness. With this work we wanted to contribute to a better understanding of some aspects related to the motivation in Portuguese football players, namely their achievement goals, perceived autonomy and beliefs about the nature of sport competence. It was also our goal to analyze the existence of a pattern of relations between the motivational determinants above.

We recruited 577 football players. Ages ranged from 15 to 39 years (M=21.71±5.65). Participants completed the following tools: Task and Ego Orientation in Sports Questionnaire (TEOSQ), Self-Regulation Questionnaire (SRQ), Questionnaire relative to Beliefs about the Nature and Determinants of Sports Competency (QCNHS). All data were analyzed using descriptive statistics and Pearson correlation coefficient ($p < 0.05$).

Our data suggest that the footballers were preferentially task oriented (4.10±.59), tended to display higher levels for the highly autonomous forms of motivation, identified regulation (4.29±.62) and intrinsic Motivation (4.10±.68), and strongly believed that their sport competence is specific (3.83±.68), due to learning (4.44±.55) and is subject to improvement (4.18±.66). Pearson correlation analyses revealed that the task orientation were significantly correlated with the introjected R., intrinsic R., intrinsic motivation and with the beliefs that the sport competence is specific, due to learning and subject to improvement (r=.32; r=.46; r=.43; r=.17; r=.42; r=.27, respectively). On the other hand, ego orientation was significantly (p<0.05) correlated with the external R., introjected R. and with the beliefs that sport competence is stable, a gift and generable (r=.11; r=.15; r=.14; r=.24; r=.13, respectively).

In accordance with other studies with sport Portuguese footballers (Fonseca & Maia, 2000), the players were more task oriented, strongly believed that their sport competence is specific, due to learning, and is subject to improvement. This is a positive and desirable tendency, because these players showed a higher perception of control during the development of their competence (Sarrazin et al., 1995). In relation to the perceived autonomy, we have seen that the values reported to the identified regulation were higher than those related to intrinsic motivation. As such, the athletes, rather than for intrinsic reasons (associated, for example, with pleasure and satisfaction inherent in the practice of football), engage in practice motivated, above all, by issues related to the importance and the value attached to football.

THE ITALIAN VERSION OF A SPORT ORIENTATION QUESTIONNAIRE: PRELIMINARY ANALYSES

SANNICANDRO, I., ROSA ROSA, A., PETITO, A., VIOLANTE, A.

UNIVERSITY OF FOGGIA, SSIS PUGLIA (SUPERVISOR SCHOOL OF SECONDARY SCHOOL TEACHER TRAINING)

Introduction: Until recently, there were no sport questionnaires available in Italy that assessed sport orientation . This study investigates the reliability and validity of the first Italian version of such a questionnaire that is an adaptation of the Sport Orientation Questionnaire (SOQ) of Gill and Deeter (1988). The questionnaire was translated into Italian with the kind permission of Doctor Diane L.Gill and various other changes were also made as recommended by the literature (Vallerand and Halliwell, 1983; Streiner and Norman 1996).

Methods: The sample was formed of n=265 students from the University of Foggia 3 year degree course in Motor and Sport Sciences (n=109, Year 1; n=111, Year 2; n=45, Year 3); mean age 21.3±2.4 years. Statistical analysis was performed upon the results of the SOQ, considering the three subscales (Competitiveness, Win and Goal) and year groups separately. The distributions of the data were assessed for skewness and kurtosis and exploratory factor analysis (EFA) was performed using varimax rotation. The internal consistency of the three subscales was assessed using Cronbach's alpha.

Results: Statistical analysis (mean ± S.D. of Year 1, Year 2 and Year 3, respectively) of the SOQ subscales showed that the highest mean values belong to the subscale Competitiveness (52.26±5.2; 52.24±5.2; 52.19±5.2); whereas, the lowest mean values belong to the Win (25.42±4.5; 25.26±4.5; 25.24 ±4.5) and Goal (25.29±2.5; 25.25±2.5; 25.25 ±2.5) orientations.

Skewness was negative with values ranging between -1.77 and 0.45; the value of the kurtosis varied between 0.5 and 3.74. EFA indicated that the three factors explain 42.496% of the total variance. The Competitiveness orientation presented the majority of the items connected to the word "victory", while the Win orientation presented the items associated to the words "points" and "competition". Interpretation of the Goal orientation was complex because the items with highest scores were also recognised in the Competitiveness subscale. The internal consistency of the Competitiveness and Win orientation subscales was very good (α=0.84 and 0.79 respectively); the extent of internal consistency for the Goal orientation subscale was very low (α= 0.46).

Discussion: These results partially support the hierarchical model of three factors, as suggested by Gill and Deeter. They indicate that a clear distinction does not exist between the three subscales and that only two factors are recognised rather than the expected three. The

sample does not identify the Win orientation as being distinct. Further research is required to establish the psychometric characteristics that would form the basis of a future adaptation of this Sport Orientation Questionnaire.

SEASONAL VARIATIONS IN SELF-DETERMINED MOTIVATION AND SYMPTOMS OF BURNOUT AND OVERTRAINING AMONG TOP LEVEL CROSS-COUNTRY SKIERS.

HEGGEBØ, F., LEMYRE, P.N., NILSEN, D.A., PENSGAARD, A.M.

COACHING AND PSYCHOLOGY

Theory: Fulfillment of the three basic needs for autonomy, competence and relatedness is crucial for individual development and well being [1]. The quest to fulfill these basic needs and whether one is successful at it will affect the quality of the motivation to initiate and pursue an activity. Thwarting basic needs and participating in sports for extrinsic reasons are believed to affect well being and lead to maladaptive behavioral outcomes [1]. Contemporary research in athlete burnout has suggested that seasonal variations in self-determined motivation are meaningfully linked to symptoms of burnout in elite athletes [2,3]. Athlete burnout is defined as a syndrome of "physical and emotional exhaustion, sport devaluation, and reduced sense of accomplishment" [4], and symptoms of overtraining have been found to be a precursor of athlete burnout [2]. Thus, the aim of this study was to add to the current body of knowledge and study how motivation and overtraining symptoms are linked to the development of burnout at a crucial training period of the season in elite x-c ski racers.

Method: A sample of elite Norwegian cross-country skiers (n = 32) aged from 18-23 years (Mode = 18), and training 700-800 hours a year participated in this study. Data were collected in November, in the pre-competitive phase, using the ABQ, SMS and SOSQ.

Results: Findings yielded a negative moderate relationship between self-determined motivation and burnout. Intrinsic motivation was moderately negatively related with the devaluation of the sport experience. A positive moderate relationship emerged between the emotional and physical exhaustion and externally regulated motivation. Additionally, amotivation was positively linked to burnout and the devaluation of the sport experience. Finally, results indicate that when athletes display high levels of self-determined motivation, overtraining symptoms are low; however when levels of self-determined motivation were low athletes experiences elevated symptoms of overtraining.

Conclusions: Current results support previous study findings in that levels of self-determined motivation in elite cross country skiers are meaningfully linked to overtraining and athlete burnout symptoms.

CHILDREN'S MAP-READING IN ORIENTEERING; A STUDY OF NATURAL, 'REAL-WORLD' MAP-READING FOR WAYFINDING

SIGURJONSSON, T.

HEDMARK UNIVERSITY COLLEGE

Sigurjónsson, T.

Hedmark University College, Faculty of health and sports, Elverum

Norway

Introduction: Children's development of experience of map-reading for way finding is of great interest for the instructor in orienteering (Ottosson, 1987). From my point of view this is interplay between the map-reader, the map and the terrain. The relative importance of each component to the overall performance in the terrain is a debated issue (Sigurjónsson, 2007). The aim of my study was to study this interplay and to characterise children's development of experiences of map-reading in orienteering.

Methods: The empirical material was generated from audio and video-taped fieldwork in a naturalistic setting with follow-up conversations where specific situations from the fieldwork were watched on a television. The techniques of head-mounted-camera were used. The method both focus on children's attention towards the map and the attention towards the environment around them. Two fieldworks where carried out. One of them took place in a school area where 16 children - 8 girls and 8 boys aged 5:11 to 9:7 - participated. The other took place in woodland in the neighbourhood of the school and 12 children - 6 girls and 6 boys aged 9:11 to 12:6 - participated.

Results: The empirical material indicates two extremes with regards to describing the interaction in the map-reading ecosystem. At the one extreme there is behaviour which is characterised by a clearly defined readiness for the forthcoming movement. This gives focal awareness and active interaction between the child, the map and the terrain. At the other extreme there is behaviour where the child only to a small degree forms a readiness for his or her movement. This gives poor interaction in the interplay. The attention is pointed towards direction and less towards specific terrain detail. Therefore the children in this case experience hesitancy, and a more active reflection where they try to focus on specific terrain detail on the map and in the terrain is initiated.

Conclusions: An important finding in the study is that the symbolic map is experienced as a difficult aid for the beginner child. Therefore the children have difficulties in building up a good state of readiness for the terrain they are to move around in. The children in the primary school carry out parts of the course with perspective maps. With this aid they are able to form more clearly defined readiness and become more focused on specific terrain details. On the basis of the findings some implications for teaching map-reading and map-understanding are discussed and a model for a progressive approach is suggested.

My results suggest that cognitive expertise in the real-world represents a key factor in teaching in orienteering and that this accelerates the development of visual attention towards relevant terrain details.

RELATIVE AGE EFFECT AMONG SWEDISH ICE HOCKEY-PLAYERS: GENDER DIFFERENCES AND RELATION TO PERFORMANCE

STENLING, A., HOLMSTRÖM, S., JANSSON, J.
UMEÅ UNIVERSITY

A systematic discrimination in sports due to birth date known as the relative age effect (RAE) has been established in both youth and professional sports. The phenomenon is explained by an over-representation of players born early in the year and under-representation of players born late in the year. This is a consequence of cut-off dates used in sports which may result in an 11 month difference in physical and cognitive maturity between a child born in January and a child born in December yet practicing in the same age group. Research on male youth ice hockey players have provided strong evidence of RAE but research on the RAE among female hockey players is lacking. Overall more RAE research among female sports is needed (Musch and Grondin, 2001). An overlooked area in the RAE field is the relationship between RAE and measures of performance. Thompson et el. (1991) attempted by looking at pitchers ERA stats in relationship to RAE but no correlation was found.

The aim of this study was twofold. First, an investigation of the distribution of birthdates among four groups of Swedish ice hockey players was conducted. Three male youth groups (n = 1188) and one female elite group (n = 180) was reviewed. The male youth players were divided into groups according to level, U-16, J-18 and J-20. Second, the relationship between distribution of birth date and performance, measured by points, goals, assists and plus-minus, was investigated. Results showed an over-representation of players born early in the year within all four groups, indicating that RAE is evident among both male youth and female hockey players in Sweden. Regarding the relationship between birth date and performance measures none reached statistically significant levels. Results are adding to the evidence of RAE among male youth players and also indicating that RAE exists among female elite players. The result of RAE among females supports Delorme and Raspauds (in press) findings, although interpretations of the result must be cautious due to the small sample size. They also provide a new dimension, RAE and performance measures, which according to results from this study indicate that players born early in the year do not perform better then players born late in the year. Results indicate that ice-hockey players are selected on criteria beyond their own control, which interferes with guidelines from the Swedish Sports Confederation, to provide equal opportunities and "Sports for All". Consequences of this discrimination will be discussed.

THE CONNECTION OF SPORT STACKING AND EYE-HAND COORDINATION IN YOUNG EXPERTS

SEIDEL, I., STEIN, T., STAHN, A., SCHOTT, N.
UNIVERSITÄT KARLSRUHE (TH)

Introduction: Sport stacking as a sport is developing fast. In the stacking community it is assumed that sport stacking promotes among other things eye-hand coordination and concentration. Till now only a few studies have been conducted in this regard (e.g. Udermann et al., 2004, Hart & Bixby, 2005). There exist no studies concerning the performance structure of sport stacking or the relevance of different motor abilities. It seems plausible to assume that eye-hand coordination is an important ability in the context of sport stacking. If eye-hand coordination has an effect on the stacking performance has not been investigated till now. The purpose of the following study is to analyse if there is a connection between eye-hand coordination and stacking performance.

Methods: We analysed 17 participants (6m, 11f) of the Sport Stacking World Cup 2007. Their age ranged from 11 to 15 years (mean=13.24, SD=1.48). All of them have at least a three-year expertise in stacking and practice three hours or more per week. To test the eye-hand coordination we used two rather general tests of the motor performance series by Schoppe (MLS, Neuwirth & Benesch, 2005). Furthermore we developed a rather specific "stack test" based on the "soda pop test" of Hoeger & Hoeger (2004). The reliability of this test was proved using a sample of 26 subjects (11m, 15f; 26,5 ± 6,2 yrs.). All tests were accomplished with the dominant (dh) and non-dominant (ndh) hand. Finally those test results have been compared to each other and to the performance in the three Stacking disciplines (3-3-3-Stack, 3-6-3-Stack and Cycle-Stack) using Pearson correlation statistics.

Results and Discussion: The test-retest-reliability indicates, that the Stack Test is reliable (dh: rtt=.81-.90, $p<.01$; ndh: rtt=.78-.89, $p<.01$). There are no correlations between the MLS tests and the Stacking disciplines. For the stack test performed with the dh we found significant correlations with the 3-6-3 ($r=.70$, $p<.01$), the Cycle ($r=.53$, $p<.05$) and no correlation with the simpler 3-3-3-Stack ($r=.23$, $p>.05$). We found no correlations for the ndh. There are also no correlations between the MLS and the Stack Test. Besides other things these findings indicate that for stacking-experts the non-specific eye-hand coordination does not have a performance defining influence. Furthermore the results denote that the eye-hand coordination of experts seems to be a task specific ability or that the eye-hand coordination adapts in a task specific way within the training process.

IS BICARBONATE A PERFORMING ENHANCING DRUG?

ZINNER, C., WAHL, P., HAEGELE, M., BEHRINGER, M., SPERLICH, B., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: During past years numerous studies analysed the effects of bicarbonate loading on performance. These studies postulate different effects of bicarbonate on blood lactate concentrations and performance of exercise bouts of different durations. Purpose of the present study was to determine the effects of bicarbonate on blood lactate accumulation, metabolism and performance. To visualize the effects of HCO3 our aim was to exhaust the "normal" in-vitro buffer capacity by short all-out intervals.

Methods: 8 male athletes (27.4 ±6years, 182.3 ±8cm, 75.6 ±9kg, 67.9 ±4ml/kg/min) performed two seperated sessions each consiting of four 30 sec lasting bike sprints on a cycle ergometer. Between the sprints subjects remained in a sedentary position on the cycle ergometer for 5 min. The sessions started with a warming up of 10 minutes at an intensity of 1.5 Watt/kg. Subjects ingested either 0.3 g/kg of sodium bicarbonate (NaHCO3) or 2 g of a Placebo (P) (calcium carbonate) diluted in 0.02 ml/kg of water over a 90 min resting period before the warming up started. Arterialised capillary blood samples (115µl) were taken from the hyperemized earlobe before ingestion, post ingestion, after the warm up and during the rest periods between each bout (30˝, 4´).

Results: Prior the ingestion, pH and [HCO3] did not differ between the two interventions ((NaHCO3) vs. (P), 7.39 ±0.02 vs. 7.39 ±0.01, 24.6 ±0.8 mmol/l vs. 24.6 ±1.4 mmol/l). The pre exercise pH and [HCO3] (post warming up (WU)) were significantly increased after ingestion ((NaHCO3) vs. (P) 30.7 ±1.3mmol/l vs. 25.4 ±1.3mmol/l, 7.46 ±0.01 vs. 7.40 ±0.01). At the end of the trials the pH was significantly lower for the P condition (7.09 ±0.04 vs. 7.16 ±0.02). At the end of the tests lactate values showed significant differences between P (16.3 ±5.8mmol/l) and NaHCO3 (20.3 ±6.6mmol/l).

The mean power (MP) showed significant differences between both conditions. During the first and the second bout performance was nearly identical (1st bout: (NaHCO3) 768 ±219W vs. (P) 769 ±250W, 2nd bout: 697 ±203W vs. 698 ±224W). The performance during the third and the fourth bout were significantly lower in the P intervention (third bout: 632 ±197W vs. 581 ±213W, fourth bout: 606 ±209W vs. 536 ±184W).

Discussion: The results of our study show significantly higher MP values during the 3rd and the 4th test after bicarbonate supplementation. Lactate is transported in a symport with H+ ions by monocarboxylate transporter proteins. Bicarbonate which does not enter the muscle therefore increases the concentration gradient of H+ ions between the muscle and the blood causing a greater efflux of H+ ions out of the muscle accompanied by lactate into the blood. The supplementation seems not to increase only the 'in vitro' buffer capacity but also the 'in vivo' buffer capacity, which is the ability of a cell to regulate pH. It can be speculated that hence the muscle is capable of maintaining performance for a longer period of time.

HEART RATE VARIABILITY IN OBESE ADOLESCENTS

STUCKEY, M.I., GUEUGNON, C., TORDI, N., MOUGIN-GUILLAUME, F., PETRELLA, R., REGNARD, J.

1. UNIVERSITY OF WESTERN ONTARIO, 2. UNIVERSITÉ DE FRANCHE-COMTÉ

Introduction: Obesity is an important risk factor for cardiovascular disease and obesity rates are increasing in all age categories including adolescents. Autonomic dysfunction is common in obese adults and adolescents. Heart rate variability (HRV) is a popular means of characterizing the autonomic nervous system since HRV values outside of the normal range are predictors of cardiovascular morbidity and mortality. The purpose of this investigation was to test the hypothesis that lifestyle modification therapies would positively affect frequency domain indices of HRV in obese adolescents. Methods: 34 Adolescents (aged 11-18) were recruited from an obesity rehabilitation centre (Maison d'enfants la beline, Salins les Bains, France). Treatment at the centre included dietary and psychological counseling as well as access to a variety of daily physical activities and medical intervention for co-morbidities. 17 adolescents followed this treatment plan and 17 attended supervised cycle exercise sessions in addition to the normal treatment. Before and after 8 weeks of exercise (2 weeks familiarization, 6 weeks training) heart rate was collected during 5 minutes of quiet, seated rest. Results: Power spectral analysis of RR intervals before and after the intervention period revealed that there were no significant changes in any frequency domain index of HRV ($p > 0.05$). Conclusion: Contrary to our hypothesis treatment for obesity did not improve HRV in adolescents. This work was funded by the Lawson Health Research Institute.

KINETICS OF O2 UPTAKE AND MUSCLE DEOXYGENATION DURING MODERATE AND SUPRA MAXIMAL INTENSITY CYCLING EXERCISE IN HUMANS

ADAMI, A., DEROIA, G., POGLIAGHI, S., CAPELLI, C.

UNIVERSITY OF VERONA - SCHOOL OF SPORT AND EXERCISE SCIENCE

Introduction: It is not still clear whether V'O2 kinetics at the onset of square-wave supra maximal (SM) exercise is faster (Hebestreit et al., 1998) or slower (Barstow and Molè, 1991, Hughson et al, 2000) than during moderate (M) intensity exercise. It has been also shown that muscle capillary perfusion response may be substantially slower than that of pulmonary gas exchanges and cardiovascular O2 delivery (Harper et al., 2006). As such, it may limit the V'O2 kinetics during exercise performed above peak O2 uptake. Therefore, the aim of this study was to analyse in parallel V'O2 kinetics and muscular deoxygenation responses at the onset of M and SM square wave exercise in humans.

Methods: 14 active male subjects (26 ± 5 yr; 175 ± 6 cm; 73 ± 5.7 Kg; V'O2max 4.13 ± 0.36 L min-1) were studied at the onset of square-wave cycling exercise of M (80% of maximal aerobic work rate) and SM (120% of maximal aerobic work rate) intensities.

B-by-B V'O2 at the mouth and muscle oxygenation of the right vastus lateralis were continuously measured (NIRS).

V'O2 kinetics at the onset of exercise was described by using two- or three-component exponential model, whereas that of the deoxygenated hemoglobin concentration ([HHb]) was described by using mono- or two-component models (DeLorey et al., 2003). This allowed calculating the mean response time (MRT) of the responses (McDonald et al., 1997).

Results: Steady state V'O2 during M corresponded to 67.8% of V'O2max; at the end of SM it equalled 95.4 % of V'O2max.

MRT of V'O2 kinetics during M was not significantly different (38.6 ± 10 s) from that found in SM (MRT 36.9 ± 9.5 s). MRTs of [HHb] kinetics were not significantly different between the two exercise conditions: M = 17.6 s ± 5.7; SM = 19.7 s ± 14.8.

Discussion: V'O2 kinetics did not differ in the two exercise modalities. These findings partially agree with of Hebestreit et al. (1998) who observed a faster V'O2 kinetics during SM exercise. However, the fitting procedure may have yielded a spuriously fast V'O2 response of SM exercise (Hughson et al, 2000). [HHb] response was similar to those described during M and severe intensity exercises (DeLorey et al., 2003, Grassi et al,, 2003). The low MRT values of [HHb] kinetics are compatible with a slow adaptation of muscular capillary blood flow at the onset of exercise (Harper et al., 2006). Nevertheless, this phenomenon, coupled with the large O2 request, did not seem to limit O2 uptake kinetics during SM exercise.

A COMPARATIVE STUDY OF SKIN BLOOD FLOW AND SWEATING RESPONSES IN CYCLISTS OF DIFFERENT AGES DURING UPRIGHT AND SUPINE CYCLING.

BEST, S., THOMPSON, M.W., TAMMAM, A.

THE UNIVERSITY OF SYDNEY

Introduction: Age related impairment in thermoregulation has been reported to be a result of a diminished capacity and/or sensitivity of the sweating response. There is evidence to suggest skin blood flow (SBF) is restricted in older adults through decreased vasodilation and splanchnic vasoconstriction. During exercise in the older trained cyclist, a diminished SBF response may be compensated for by an increased reliance on sweating. This is somewhat analogous to the onset of exercise when vasodilation is delayed and the increase in body temperature stimulates a compensatory increase in sweating. Comparing SBF and sweat responses during upright exercise and supine exercise, where SBF has been shown to increase 1, may potentially identify the relative contribution of SBF and sweating to thermoregulation in young and older trained cyclists.

Method: An older (50-70yrs, n=4) and younger (age 20-35yrs, n=4) group of highly trained male cyclists were recruited to the study. Testing was performed on an electromagnetically braked cycle ergometer modified to be used in the upright and supine positions. Each subject completed a VO2max test in the upright and supine positions, before 3 cycling sessions of 60mins in the same hot environmental conditions (35oC, 40%RH). The 3 heat tests varied in cycling position and intensity: 1) Cycling upright (U) at 70% Upright VO2max, 2) Cycling supine (SU) at 70% Upright VO2max, 3) Cycling Supine (SS) at 70% Supine VO2max. Rectal temperature (Trec), skin temperature (Tsk), Whole body sweat rate (Swb), Local sweat rate (Swl) and skin blood flow (SBF) were measured throughout each of the 3 exercise heat tests.

Results: All subjects completed the 60mins in the upright position but 5 could not complete the SU test (Y=4, O=1) and 2 could not complete the SS test (Y=2). Final Trec, Tsk and SBF values in the U, SU and SS heat tests were similar between the 2 age groups. Final Swl was similar in the U (1.56 ±0.24 mg.min-1.cm2, 1.65 ±0.42 mg.min-1.cm2), SU (1.39 ±0.19 mg.min-1.cm2, 1.39 ±0.26 mg.min-1.cm2) and the SS test (1.37 ±0.29 mg.min-1.cm2, 1.31 ±0.33 mg.min-1.cm2) for the young and older groups respectively. Swb was greater in the younger than the older group respectively for the U (1.91 ±0.29 L.hr-1, 1.62 ±0.19L.hr-1), SU (2.16 ±0.48L.hr-1, 1.68 ±0.13L.hr-1) and SS (2.09 ±0.39L.hr-1, 1.59 ±0.20L.hr-1) heat tests. Tsk and SBF values were higher and Swl lower for both age groups during the supine tests when compared to the upright test. No difference in Swb was observed between upright and supine tests.

Discussion:

Preliminary results suggest no observable differences in skin blood flow or sweating response in highly trained older and younger cyclists, in either upright or supine cycling positions. If age related differences do exist they may need a protocol that exposes cardiovascular limitations such as the decline in VO2max as a consequence of sedentary living or an inherent outcome of ageing.

USING META-ANALYTICAL AND EXPERIMENTAL APPROACHES TO EXPLORE WHETHER BLOOD PRESSURE STATUS REALLY IS THE MOST IMPORTANT DETERMINANT OF POST-EXERCISE HYPOTENSION

TAYLOR, C., CABLE, T., JONES, H., HADCROFT, J., ZAREGARIZI, M., ATKINSON, G.

LIVERPOOL JOHN MOORES UNIVERSITY, AND LIVERPOOL HEART AND CHEST HOSPITAL

Introduction: It has been maintained, both at the individual (Pescatello et al., 2004a) and whole-study (Pescatello and Kulikowich, 2001) levels, that blood pressure (BP) status is the most important determinant of post-exercise hypotension. This claim is incorporated into the ACSM position on hypertension (Pescatello et al, 2004b) and is based on reports that exercise-mediated changes in BP are correlated to BP measured pre-exercise (PRE). Recently, this analysis has been questioned on the basis of potential regression-to-the-mean (RTM) effects (Atkinson et al., 2005). Past syntheses of study results have also not involved standard meta-analytical weighting. The present aim is to examine the degree to which BP status moderates post-exercise hypotension, via a novel combination of formal meta-analytical and experimental approaches, while controlling for RTM.

Methods: As part of a systematic review of 67 studies (n=1155 participants), the reported exercise-mediated changes in daytime and nocturnal BP were meta-regressed against PRE, and against the mean of pre- and post-exercise BP, which is an index of BP status not prone to RTM. In a related experiment, 32 participants cycled for 30 min at 70% peak oxygen uptake (VO2peak). Systolic and diastolic BP, and mean arterial pressure (MAP) were measured (Portapress) at baseline and for 20 min following exercise. Relations between BP change, BP status and other potential moderators were described with regression analyses. Data are described as mean (95% confidence limits).

Results: The meta-analysed reductions in BP ranged from 3 to 7 mmHg, with larger declines found for studies with ambulatory BP monitoring periods of <24 h. For daytime BP, the regression slopes between BP status and change were ≈ -0.2 (P<0.00005) and consistent between PRE and mean BP status. For nocturnal BP, the relationship between BP status and change was clearly attenuated when RTM was controlled. In the experiment, the regression slope between PRE and change in MAP was -0.3 (0.0 to -0.6) mmHg (P=0.03), but this relationship did not exist when mean BP was used (P=0.99). Moreover, use of mean BP led to other moderators, such as age, BMI and VO2peak being statistically significant moderators of BP change (P<0.05).

Discussion: These data, collected at whole-study and individual levels, indicate that BP status is not as important as was thought in determining the degree of post-exercise hypotension, especially in past studies in which the follow-up period extended over the nocturnal period. This finding, together with our suggestion that other individual factors might be important moderators of post-exercise hypotension, should be used to update position statements on post-exercise hypotension.

DOES CYCLING AFFECT MOTOR COORDINATION OF THE LOWER LIMBS DURING RUNNING TO EXHAUSTION IN WELL-TRAINED TRIATHLETES?

BIEUZEN, F., LE MEUR, Y., DOREL, S., BRISSWALTER, J., HAUSSWIRTH, C.

NATIONAL INSTITUTE OF SPORTS AND PHYSICAL EDUCATION

PURPOSE – Triathletes report incoordination when running after cycling. In recent study, Chapman et al. [1] have tried to measure this on one muscle: the tibialis anterior (TA). They showed that TA recruitment does not change during cycling to running transition. However, running and cycling imply the coordination of many muscles, and lots of works showed that fatigue affect not only the TA but also the other muscles of the lower limb. Within this framework, the aim of this study was to analyse the effect of cycling on the locomotor pattern during running to exhaustion from measurements of the electromyographic surface activity of nine muscles of the lower limb.

METHODS – We compared surface electromyographic (EMG) recording from nine muscles of the lower limb (biceps femoris (BF), semitendinosus (SM), vastus lateralis (VL), the rectus femoris (RF), the vastus medialis (VM), the gastrocnemius lateralis (GL), the gastrocnemius medialis (GM), soleus (SOL) and tibialis anterior (TA)) during running to exhaustion (Tlim) immediately after 30min of cycling with a control-run (CR) test (no prior exercise). For each running test realised on a treadmill, intensity corresponding to the one measured at the second ventilatory threshold during a previous incremental running test. Three periods were compared: 75% of the five minute of the CR, 5% and 95% of the total time of the Tlim.

RESULTS – The magnitude of the mean EMG RMS over the complete stride for the SM decrease significantly (p<0.05) between CR and the 5% and 95% of the Tlim. The mean EMG RMS for the GM decrease significantly (p<0.05) from 5% to 95% of the Tlim. The k values resulted from the cross-correlation technique [2] indicated that the activity of all muscles measured were not shifted in the stride but variability in muscle recruitment between athletes is great.

CONCLUSION – Our results suggest that cycling does not influence running pattern of the main muscles of the lower limbs for well-trained population. However, using a treadmill modifies the EMG pattern of leg muscles [3] and could explain that. Moreover, contrary to previous studies, the leg muscle activity during running is not influenced neither by cycling nor fatigue except for SM and GM muscles. These results suggested that for training athlete locomotor pattern does not change over short period of running on treadmill even if it was conducted until exhaustion.

EFFECTS OF A SINGLE MANUAL MASSAGE TREATMENT ON THE SYMPTOMS OF EXERCISE-INDUCED MUSCLE DAMAGE IN YOUNG ACTIVE WOMEN

JAKEMAN, J., DAY, J., BYRNE, C., ESTON, R.

UNIVERSITY OF EXETER

Effects of a single manual massage treatment on the symptoms of exercise-induced muscle damage in young active women

J.R. Jakeman, J.E. Day, C. Byrne., and R.G. Eston.

Introduction: Manual massage is a widely used treatment strategy for athletes preparing for, or recovering from athletic activity. Recent studies reporting the efficacy of massage on exercise-induced muscle damage however are equivocal. The aim of this study was to establish the effectiveness of a single bout of manual massage immediately following exercise on recovery from exercise-induced muscle damage (EIMD).

Methods : Sixteen physically active female volunteers (age 21.3 (1.6) y; height 1.66 (0.04) m; body mass 64.4 (7.3) kg) completed 5 x 8 min bouts of downhill running at -10% gradient and 12 km/h to induce muscle damage. Volunteers were randomly assigned to a control (n = 8) or treatment group (n = 8). A 30-min sports massage was administered by a qualified sports masseur to the legs of participants in the treatment group immediately following downhill running. Indicators of muscle damage (creatine kinase activity, perceived soreness, and maximal voluntary contraction of the quadriceps) were assessed immediately prior to and 1, 24, 48, 72, and 96 h following damaging exercise.

Results: Downhill running exercise had a significant (p ≤ 0.05) effect on all indices of exercise-induced muscle damage. No treatment effect was observed on creatine kinase activity or perceived soreness. However, the percentage peak torque decrement was moderated by the massage treatment (1 h, 81% v 91%; 24 h, 83% v 89%; 48 h, 82% v 87%; 72 h, 84% v 93%; 96 h, 90% v 97% following damaging exercise for the control and treatment groups respectively).

Discussion: Although manual massage treatment had no significant effect on perceived soreness or creatine kinase activity, it reduced the decrement in strength following EIMD. The positive effect of the massage treatment may be due to the early intervention in the inflammatory process, limiting the formation of oedema, and promoting an elongated period of neutrophil elevation, aiding the removal of cellular debris. Practically, athletes involved in multiple events in a short space of time may find performance is less adversely affected by a recovery strategy of this nature.

EFFECTS OF COMBINED ENDURANCE AND STRENGTH TRAINING ON MUSCLE STRENGTH AND MORPHOLOGY IN 40-70 YEAR OLD MEN AND WOMEN

KARAVIRTA, L., HÄKKINEN, A., SILLANPÄÄ, E., KAUHANEN, A., ARIJA BLÁZQUEZ, A., HAAPASAARI, A., KRAEMER, W.J., ALEN, M., IZQUIERDO, M., GOROSTIAGA, E., HÄKKINEN, K.

UNIVERSITY OF JYVÄSKYLÄ

Introduction: Strength training improves maximal strength through several mechanisms, e.g. increased voluntary muscle activation and changes in muscle morphology (1), not only in young but also in older adults (2). However, the strength gains and hypertrophy may be compromised in high volume combined endurance and strength training in young adults (3). This study examined the effects of combined training on muscle strength, fibre size and composition in 40-70 year old men and women.

Methods : 30 male (57 (SD 7) yrs) and 47 female (51 (8) yrs) volunteers completed a 21-week training period of either strength training (S, men n=11, women n=16), endurance training (E, M n=7, W n=16) or their combination (SE, M n=12, W n=15). Measurements included maximal isometric bilateral force of the lower extremities (F), and maximal aerobic power (Pmax) in a bicycle ergometer test to exhaustion. Muscle biopsies were obtained from VL for analyses of muscle fibre type and CSA. Progressive total body strength training with loads up to 80 % of 1RM was performed twice a week. Endurance training was cycling twice a week with intensity ranging from moderate in steady pace sessions to near maximal in short intervals. The combined strength and endurance training included both training programs, resulting in a total of 4 weekly sessions.

Results: Men and women in SE increased their F by 19 (14) % and 19 (19) % ($p<0.01$), and Pmax by 12 (7) % and 18 (9) % ($p<0.001$), respectively. In S the changes in F were similar, 15 (10) % and 22 (15) %, whereas Pmax only increased by 6 (4) % and 8 (11) % ($p<0.01$). In E Pmax increased 11 (7) % and 18 (8) % in men and women, but F did not change significantly. The CSA of type II muscle fibres increased ($p<0.05$) in S in both men and women, while in E only in women ($p<0.01$). The area of type IIA fibres increased in the male S and the female E group. No significant changes in muscle fibre size were observed in SE. The relative proportion of IIA fibres increased and IIAX decreased in both men and women in S. The proportion of IIAX also decreased in the female SE group ($p<0.01$).

Discussion: Strength training in both men and women, and endurance training by high intensity cycling in women only, elicited an increase in the CSA of type II muscle fibres in previously untrained older subjects. However, moderate volume combined training did not lead to significant increases in muscle fibre size in men or women, regardless of the same amount of strength training performed. This finding indicates possible interference of muscle hypertrophy when strength and endurance training are combined over a prolonged training period even in older subjects. Nonetheless, strength performance was improved with combined training similarly as with strength training alone possibly due to neural adaptations.

HAEMOGLOBIN MASS, HCT AND [HB] THROUGHOUT A 6 D UCI PROTOUR CYCLING RACE

GARVICAN, L.A., MARTIN, D.T., EASTWOOD, A.,3, ROSS, M.L.,4, ABBISS, C.R.,4, GRIPPER, A., ZORZOLI, M., SCHMIDT, W.6, GORE, C.J.,2

1. AUSTRALIAN INSTITUTE OF SPORT (CANBERRA, AUS), 2. FLINDERS UNIVERSITY (ADELAIDE, AUS), 3. SASI (ADELAIDE, AUS), 4. ECU (PERTH, AUS) 5. UCI (AIGLE, CHI), 6. UNIVERSITY OF BAYREUTH (BAYREUTH, GER)

Introduction: Haemoglobin concentration [Hb] and haematocrit (Hct) generally decrease in response to multiple days of cycle racing due to a plasma volume expansion. In contrast, preliminary evidence suggests that Haemoglobin mass (tHb) remains stable during short stage races. The aim of this study was to document the variability of tHb, [Hb], and Hct in cyclists participating in a UCI ProTour event.

Method: tHb was measured using the carbon monoxide rebreathing test in 6 male cyclists (CYC; Mean ± SD age 24 ± 5y, height 179 ± 5cm, mass 71 ± 4kg) and 5 controls (CON; 31 ± 6y, 179 ± 6cm, 74 ± 6kg) throughout an international calibre stage race (Tour Down Under, UCI Pro Tour). The 6-day race covered 802 km in 19.5 h of racing during the Australian summer (24-39 C). tHb was measured on 7 consecutive days. Results from the first two tests were averaged to establish Baseline. On race days, tHb was measured daily within 4 h of the stage finish. No measures were performed on the last race day. Early morning, fasted venous blood samples were collected 2 d before the start of the tour (D0), after 2 d of racing (D4) and prior to the last stage (D6) in accordance with UCI guidelines. Venous blood was collected into an EDTA Vacutainer, and analysed within 12 h of collection for Hct and [Hb]. The reliability of the tHb technique was presented as a Typical Error (TE). Mean effects of log-transformed data were estimated via the unequal-variances t statistic computed for change scores between tests. A coefficient of variation (CV) was calculated for each subject to assess within-subject daily variability.

Results: TE for tHb at Baseline (n=11) was 1.3%. tHb of the CYC remained within ± 1.9% (20g) of baseline (mean ± SD; 997 ± 67g) throughout the tour (range: -1.9% D5 to 1.3% D2). Mean tHb of CON remained within 0.5% (5g) of baseline (D0 = 901 ± 113g) during the same period. There were no substantial differences in the daily change scores between CYC and CON. The mean CV for tHb during the tour was 1.5% in CYC vs. 1.2% in CON. Individual CVs ranged from 0.3-2.3% in CYC and from 0.7-1.7% in CON. CYC Hct (D0 = 0.44 ± 0.02) decreased by 5.7 ± 2.9 % at D4 and 8.1 ± 2.8 % at D6. However, CON Hct (D0 = 0.46 ± 0.01) was similar on D4 but 3.3 ± 2.6% lower on D6. CYC [Hb] (D0 = 154 ± 6.4 g.L-1) decreased by 7.7 ± 3.8% at D4 and 9.7 ± 3.2% at D6. CON [Hb] (D0 = 149 ± 9.6 g.L-1) remained similar on D4 and D6. The decrease in [Hb] at D6 was substantially lower in CYC vs CON ($p=0.003$).

Discussion: Similar to previous observations, a warm 6 d stage race can decrease Hct (~8%) and [Hb] (~10%) in professional road cyclists. In contrast, the individual CV for tHb was less than 2.5% in all cases suggesting that tHb remains relatively stable. These data indicate that a change from baseline values by as much as 2.5% during a 1 week stage race could be considered "normal". Further research is required to establish the normal variability of tHb during 1-3 wk stage races in elite cyclists.

THE DEPLETION OF A FIXED ANAEROBIC ENERGY STORE DOES NOT EXPLAIN TASK FAILURE DURING HIGH-INTENSITY EXERCISE

DE VRIJER, A., BISHOP, D.

UNIVERSITY OF VERONA

THE DEPLETION OF A FIXED ANAEROBIC ENERGY STORE DOES NOT EXPLAIN TASK FAILURE DURING HIGH-INTENSITY EXERCISE

Introduction: Exercise at intensities above VO2max can only be sustained for several minutes. As the energy required to exercise at such intensities can, by definition, not be generated solely by the aerobic system, the cause of task-failure has often been attributed to the exhaustion of anaerobic energy stores. This is the basis of the critical power (CP) model, which states that, when the required power exceeds the maximum power of the aerobic system (the so-called CP), task failure will coincide with the depletion of a fixed anaerobic energy store. The obvious corollary of this is that following task failure, subjects will not be able to continue exercising unless the power output is decreased to below the CP. The purpose of the present study was to test this hypothesis.

Methods: Seven healthy males each performed an incremental test on a cycle ergometer to determine their power at VO2max (P100%), followed by a familiarisation trial and 4 time-to-task failure (TTF) tests at 120% of VO2max (P120%). The first 3 TTF tests were identical and used to determine TTF at P120% (TTF_120). To ensure that TTF_120 represented the maximum performance of the subjects at this intensity, only the best TTF of the three tests was used. The last TTF test was similar to the first three, but the subjects were now instructed to continue exercising until TTF_120, if possible, and at the moment they reached this time, power output was decreased to P105% and subjects were asked to continue again as long as possible (TTF_105). Capillary blood was sampled before each test, at task failure, and after 5 min of recovery at 60W.

Results: All subjects were able to reach TTF_120 (186 ñ 32 s) during the final TTF test. Six of the subjects were able to continue exercising at P105% for over 25 s (mean TTF_105 was an additional 61 ñ 48 s). There was no significant difference between the [BLa] of TTF_120 and TFT_105 measured during rest (0.9 ñ 0.2 vs. 0.9 ñ 0.1 mmol/L) or at task failure (13.9 ñ 2.7 vs 14.9 ñ 3.2 mmol/L), but [BLa] was significantly different after the 5 min of recovery (14.3 ñ 1.9 vs 15.6 ñ 2.1 mmol/l). Also the heart rate was significantly higher after TTF_105 (185 ñ 9 bpm) than after TTF_120 (179 ñ 8 bpm). There was no significant difference between the VO2 after TTF_120 and TTF_105 (49.0 ñ 5.6 vs. 51.3 ñ 4.0 ml/kg/min).

Discussion/Conclusions

After cycling to task failure at P120%, six of the seven subjects were able to continue exercising at P105%. These results cannot be explained by the critical power model, since this model predicts that the anaerobic work capacity must have been depleted at TTF_120, making it impossible to continue exercising at any intensity above CP (i.e., requiring a further anaerobic contribution). Thus, our results suggest that the depletion of a fixed anaerobic energy store does not explain task failure during high-intensity exercise.

HANDGRIP STRENGTH AND FOREARM VASCULAR FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

KEEWAN, E., ALOMARI, M., ALAWNEH, K., IBRAHEEM, R., KHATIB, S.

JORDAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Rheumatoid arthritis (RA) is associated with compromised arterial function (AF) attributed to endothelium-dependent and independent structural and functional changes. Additionally, physical activities (PA) play a critical role in enhancing vasodilatory capacity subsequent to improved fitness level (FL) in healthy and diseased populations. Despite the accumulating evidence describing the benefits RA patients gain from participating in regular PA, the relationship between FL and AF in RA patients is not clear. Accordingly, the current study examined the relationship between maximum handgrip strength (MHGS) and AF measures in RA patients.

METHODOLGY

Measures of AF and MHGS were examined in 22 RA patients (PT) and 13 healthy controls (CT) with age range (17-49). Dominant forearm arterial inflow (BF), at rest (RBF) and after 5 minutes of upper arm occlusion (IBF), were obtained using strain gauge plethysmography. Subsequently vascular resistances (VR) at rest (RVR) and after occlusion (IVR) were calculated with mean arterial pressure/BF. Average MHGS was calculated after 3 consecutive allout gripping trials with hand dynamometer. Student t-tests were used to compare forearm AF measures and MHGS between PT and CT groups whereas measures of forearm AF relationships with MHGS were evaluated using Pearson correlation.

RESULTS: Forearm RBF (CT: 3.8 ± 0.8 vs. PT: 3.0 ± 1.2 ml/100ml/min; p=0.03), and IBF (CT: 31.7 ± 7.3 vs. PT:18.0 ± 5.9 ml/100ml/min; p=0.0001) were greater in the CTs, whereas RVR (CT: 23.6 ± 3.9 vs. PT: 33.0 ± 15.4 U; p=0.01), and IVR (CT: 2.8 ± 0.5 vs. PT: 5.9 ± 3.9 U; p=0.001) were less in the CTs. Similarly, MHGS in the CTs was greater than in the PTs (CT: 32.5 ± 13.4 vs. PT: 21.3 ± 11.3 Kg; p=0.02). Finally, MHGS correlated positively with RBF (r=0.5; p=0.002), and IBF (r=0.7; p=0.0001) as well as negatively with RVR (r=- 0.3; p=0.07), and IVR (r=- 0.4; p=0.04).

DISCUSSION: The results confirm previous studies indicating diminished AF and MHGS in RA PTs. However the relationships between forearm AF and MHGS suggests that FL contribute to enhancing the vasculature in RA PTs. Additionally the association between forearm AF measures and MHGS suggest that AF is locally controlled in RA PTs.

MODULATION OF HOFFMANN REFLEX: THE ROLE OF GROUP III-IV MUSCLE AFFERENT FIBERS

LAURIN, J.

MOVEMENT SCIENCE INSTITUTE (UMR-CNRS 6233)

Introduction: The Hoffmann (H) reflex is frequently used to explore the spinal sensorimotor plasticity in response to physical exercise or to training. However, neural mechanisms responsible of H-reflex modulation after exercise remain unclear. Numerous studies suggested

that one pathway able to modulate H-reflex could originate from group III and IV afferent fiber activation. For the first time, we have identified directly the effect of metabosensitive group III-IV muscle afferent fibers on H-reflex changes in animal quadriceps and tibialis anterior muscles.

Methods: After identification of KCl doses able to elicit a maximal activation of group III and IV afferent fibers, we evoked consecutive H-reflexes on rat quadriceps or tibialis anterior muscles. Consecutive maximal H-reflexes (inter-stimulus: 10 s) and, then, consecutive evoked Mmax were elicited before and after intra-arterial KCl injections (0.5 mL). A capsaicin-treated group (suppression of thin muscle afferent) followed the same procedures. The Hmax/Mmax ratio and the corresponding MHmax/Mmax ratio were measured.

Results: A peak discharge was found after KCl injection at the dose of 10mM (+3.27±0.47 Hz, 108.9±1.2 % of the corresponding reference discharge). The Hmax/Mmax ratio was significantly attenuated after the KCl injection (-23.9±4.6% of the corresponding reference ratio, $p<0.01$) in quadriceps muscle. In capsaicin-treated rats, no significant decline in Hmax/Mmax ratio was observed after the KCl injections. No difference was observed in MHmax/Mmax ratio in all animals.

Discussion: Metabosensitive group III-IV afferent fibers from quadriceps muscle exerted an inhibitory effect on quadriceps H-reflex excitability. The Hmax/Mmax ratio declines in response to KCl injection reinforce the hypothesis that these thin muscle afferent fibers could exert reflex inhibition of α-motoneurons when metabolites accumulation in muscle occurs. This mechanism could explain the H-reflex decline reported during and after exhaustive exercises (Garland, 1991; Duchateau et al., 2002; Dousset et al., 2007).

CAN BIGOREXIA BE CONSIDERED AN EATING DISORDER?

PAPAIANNI, M.C., IONA, T., SEGURA GARCÍA, C., PROCOPIO, L., AMMENDOLIA, A.

UNIVERSITY OF CATANZARO

INTRODUCTION. Bigorexia, a frequent disorder among bodybuilders, is not yet included in actual classification systems. The aim of the study is to evaluate the possible association between exercise, body image disorders and eating disorders in bodybuilders and to compare to over-exercised women and to eating disordered women.

METHODS. 134 voluntaries who habitually train (86 men and 48 women) and 20 eating disordered women were enrolled and interviewed by observators with appropriate training in this field. All subjects have been evaluated using Eating Disorder Inventory-2 (EDI-2), Body Uneasiness Test (BUT), Muscle Dysmorphia Inventory (MDI) and a dieting and physical exercise behaviour questionnaire.

RESULTS. All women, patients (EDW) and over-exercised (OEW), would like to lose weight. The 55% of men would like to increase their weight (IWM) and the remaining to become thinner (DWM). IWM showed very significant differences from the other groups: they did not induce vomiting but they administrated themselves food integrators; there were any differences in the use of diuretics or laxatives between groups. Women (EDW & OEW) had higher mean values in EDI-2, body dissatisfaction and seemed to take care more about gaining weight than men (IWM & DWM) at BUT. In MDI the IWM showed the highest scores.

DISCUSSIONS. A similar behaviour has been observed in EDW, OEW and DWM regarding weight and body shape concerns. The behaviour of men bodybuilders to increase muscle mass seems very different and they risk becoming bigorexic. They consider the thinness as a physical defect: from the beginning, they habitually train until the training becomes a dependence looking for body perfectionism. Positive reinforcements are hyperproteic and hypolipidic diets and the use of anabolic substances. These results suggest to consider bigorexia a new cross disorder between eating and dysmorphic disorders.

EFFECTS OF SUPINE POSITION WITH LOWER LIMB ELEVATED ON CARDIAC PARASYMPATHETIC REACTIVATION AFTER EXERCISE

KAZUKI, N., AKIRA, Y., NOBORU, T., SHO, O.

HIROSHIMA INSTITUTE OF TECHNOLOGY

Introduction: We suggested supine floating after high and moderate intensity exercise could be increased the reactivation in cardiac parasympathetic which was inhibited by exercise. This is caused by increased venous return. At resting, supine position with lower limb elevated increase venous return. Purpose: The purpose of this study was to determine the effects of Supine position with lower limb elevated on cardiac parasympathetic reactivation after exercise. Methods: Seven healthy males volunteered for this study. Their mean age, height, and body weight were 22 ± 2 years (mean ± SD), 172.1 ± 6.5 cm, 64.5 ± 6.6 kg, respectively. All subjects signed an informed consent form prior to participation in this study. Subjects performed exercise with a cycle ergometer by 80 and 40% peakVO2 for 15 min., and recovered for 15 min. at supine position with elevation of lower limb (SELL condition) by 30 degree and at simple supine position (Control condition). Heart rate and cardiac autonomic nervous system activity assessed by heart rate variability (MemCalc method) were measured throughout experimental period. Cardiac parasympathetic nerve activity was evaluated by using high frequency (HF; 0.15-0.40Hz) in R-R intervals. HF domain was transformed into logarithmic values. We used the slope in regression line calculated by appearance time and peak of HF, as cardiac parasympathetic reactivation. Results and Discussion: Heart rate increased up to about 180 and 110 bpm during high and low intensity exercise period and was no significant differences between the SELL conditon and the Control condition, respectively. In high intensity exercise, log HF and slope in regression line in the SELL conditon was significantly higher than the Control condition, suggesting that elevation of lower limb at supine position may increase reactivation in cardiac parasympathetic nerv-

ous after exercise via the increased venous return during 0-5 min. recovery process. However, during 6-10 and 11-15 recovery period, there was no significant difference of log HF between the SELL condition and the Control condition. In high intensity exercise, there was no significant difference of log HF between the SELL condition and the Control condition. These data suggest increased cardiac parasympathetic nerve with high- intensity exercise may be improved early by elevated lower limb at supine position after high-intensity exercise. In conclusion, supine position with lower limb elevated after exercise may enhance the cardiac parasympathetic reactivation during recovery.

DYNAMICS OF OXYGEN CONSUMPTION AND WORKING MUSCLE OXYGENATION DURING EXERCISE WITH DIFFERENT LOAD PROFILES

POPOV, D., MARCHENKO, D., KUZNECOV, S., BOROVIK, A., VINOGRADOVA, O.

SSC RF INSTITUTE FOR BIOMEDICAL PROBLEMS

Cardio-respiratory indices respond to an abrupt increase of load with considerable time delays. These delays differ from one index to another. The goal of the study was to compare responses of cardio-respiratory system and oxygen consumption in working muscle during exercises with different load profiles.

7 endurance trained athletes gave their informed consent to participate in the experiment. VO2max and anaerobic threshold at blood lactate level 4 mmol/l (AT) were determined during ramp test on a cycling ergometer at the first day of an experiment. The next days the subjects performed two tests in random order. During the first test after 8 min warming up at 40% AT the load was abruptly increased up to 110% AT and then was gradually decreased during 4 min to the basic level of 40% AT. A reverse profile was used in a second test: gradual increase of load for the 4 min and then abrupt decrease to the initial level. Peak load and total mechanical work were the equal for both tests. oxygen consumption, HR, EMG activity of m. vastus lateralis, muscle oxygenation index (MOI) and deoxygenated hemoglobin (HHb) content in m. vastus lateralis were recorded continuously during the tests. Blood lactate concentration was measured every 30 s. In addition the subjective perception of exertion was evaluated for each exercise load.

EMG activity did not differ between loads with different power profiles. Total oxygen consumption and total number of heart beats during exercise and 2 min recovery period did not differ either. Peak values of oxygen consumption, HR, MOI and HHb were significantly ($p<0.05$) higher during exercise with gradual increment of load in comparison with abrupt load increase. At the same time peak lactate concentration in blood and subjective perception of exertion had a tendency ($p=0.09$ and 0.11) for an increase at exercise with a gradual load increment.

Thus during exercise with gradual load increment HR, the indices of oxygen consumption at muscle (HHb, MOI) and oxygen consumption of organism had enough time to adjust to load and recruitment of high-threshold muscle fibers at peak work intensities takes place under more aerobic conditions.

THE EFFECTS OF INCREASED VENTILATION DURING MODERATELY HEAVY AND MAXIMAL EXERCISE

RIISE MIDTUN, I., HEM, E., INGJER, F.

NORWEGIAN SCHOOL OF SPORT SCIENCE

Introduction: If the pulmonary ventilation is expressed in relation to the magnitude of oxygen uptake, it is 20 to 25 L per liter of oxygen at rest and during moderately heavy exercise. During maximal exercise it increases to 30 to 40 L per liter of oxygen (Åstrand et al. 2003). It takes some time before the ventilation reaches this ventilation demand. The aim of this study was therefore to make the subjects ventilate the ventilation demand from the start of the exercise, and see if there was any change in time to exhaustion. Furthermore, physiological parameters like arterial O2 saturation (SpO2), heart frequency (HF), VO2, VO2max and lactate concentration in blood [la] have also been studied.

Methods: 17 subjects, VO2 peak 4.16 ± 0.18 l/min (mean±SEM), performed all the tests running on a treadmill. On the first day of testing, the subjects performed a lactate threshold test, and a VO2max test. The second day they performed a performance test. All tests were completed two times, pre and post. The subjects performed the pre test without receiving any instructions considering ventilation. At post test they were asked to increase their ventilation from the start of the exercise, up to minimum of the ventilation demanded.

Results: The test time to exhaustion concerning the performance test increased from (mean±SEM) 316 ± 16.8 seconds (pre), to 342 ± 25.3 seconds (post) ($p=0.08$). SpO2 increased from pre to post in all three tests, with both significant ($p<0.05$) and non significant changes. HF tends to be lower at post test compared to pre test. At low and moderate intensity VO2 tend to decrease from pre to post. VO2max did not change from pre to post. From pre to post test [la] increased significant ($p<0.05$) at the performance test .

Discussion: The increase in time to exhaustion may be explained by the increased SpO2, since a high level of SpO2 is important to maintain an optimum oxygen delivery to the working tissue. The increase in [la] at the performance test can be explained by the increased time to exhaustion at the same test. Small or even lack of significant changes can be explained by the relative small number of subjects. It is also important to be aware that the subjects had a relative low aerobic capacity, which might have affected the Results: References

ESTIMATES OF VENTILATION FROM MEASUREMENTS OF RIB CAGE AND ABDOMINAL DISTANCES: AN INDIVIDUAL CALIBRATION PROTOCOL

GASTINGER, S., SEFATI, H., NICOLAS, G., SOREL, A., GRATAS-DELAMARCHE, A., PRIOUX, J.

LABORATORY «MOVEMENT, SPORT, HEALTH» (M2S): PHYSIOLOGY AND BIOMECHANICS.

Preambule:

"The use of pulmonary ventilation as an index of energy expenditure (EE) has been proposed by Durnin and Edwards and by Sortorelli" [1]

Study objectives:
The purpose of this study is to validate a new device designed to measure ventilation (VE), tidal volume (VT), inspiratory time (TI), and expiratory time (TE) during daily life activities. The first part consists in establishing a calibration protocol (days 1 and 2), that takes into account the NEAT (Non Exercise Activity Thermongenesis [2]) components: sitting, standing and walking activities. The second part (day 3) evaluates the accuracy of this new device to measure VE, VT, TI and TE in these three different conditions.
Materials and Methods: Twelve healthy males (26.9 +/- 4.6 years) volunteered to take part in this study.
The calibration maneuvers (days 1 and 2) was made up of 3 successive sessions. The sitting and standing sessions were divided into 3 periods. During these 3 different periods the subjects were instructed to take breaths in a natural way, then while primarily using the rib cage and finally while primarily using the abdomen. The exercise session was composed of treadmill walking at 4, 5 and 6 km.h−1. A second session of measurements (day 3) was realized to apply and verify the validity of the calibration maneuvers. This second session consists of a sitting and a standing session at rest and a walking session on a treadmill.
The anteroposterior displacement of the rib cage and abdomen, and the axial displacements of the chest wall and the spine, were measured using two pairs of magnetometers (Nomics-WSL2, Belgium). VE was estimated from these four signals, and was simultaneously measured using a spirometer (SP304, Bioseb).
Results: A total of 1,439 breaths were analysed for resting conditions (sitting and standing) and 1,138 breaths were analysed for walking exercises. We compared VE, VT, TI and TE measured by magnetometers (VEmag, VTmag, TImag, and TEmag) with VE, VT, TI and TE measured by spirometer (VEspiro, VTspiro, TIspiro and TEspiro respectively). We found that VTmag was highly correlated with VTspiro in sitting (r^2=0.92) and standing position (r^2=0.94) at rest, and during walking exercise (r^2=0.90) for pooled data. TImag and TIspiro values and TEmag and TEspiro values also were highly correlated in sitting (r^2=0.99 and r^2= 0.97, respectively) and standing position (r^2=0.98 and r^2=0.96, respectively) at rest, and during walking exercise (r^2=0.96 and r^2=0.95, respectively). Finally, VEmag is predicted with an accuracy of 94%, 91% and 92% compared to VEspiro, during sitting, standing and walking session respectively.
Conclusion: This study revealed that this portable and non-invasive device provided a valid and reliable measure of VE and in fine an estimation of EE in free-living conditions and sports exercises.

HEART RATE DYNAMICS IN DIFFERENT LEVELS OF ZEN MEDITATION

PERESSUTTI, C., MARTÍN-GONZÁLEZ, J.M., GARCÍA-MANSO, J.M.
UNIVERSIDAD DE LAS PALMAS DE GRAN CANARIA

HEART RATE DYNAMICS IN DIFFERENT LEVELS OF ZEN MEDITATION
Introduction: The dynamic interactions among physiological rhythms imbedded in the heart rate signal can give valuable insights into autonomic modulation in conditions of reduced outward attention and voluntary responsiveness. Therefore, the aim of this study was to analyze the heart rate variability (HRV) and breathing behavior during Zen Buddhist meditation (Zazen).
Methods : Nineteen subjects with regular practice and variable experience in Zazen took part in this study. Data from heart rate and breathing were collected simultaneously during twenty minutes of quietly sitting meditation. Data analysis was performed using two methods: the Fast Fourier Transform, which reflects the strengths of the frequency components of the signal, and the Continuous Wavelet Transform, which decomposes a series into time-scale or time-frequency domains and allows for the identification of temporal changes of dominant modes of variability. We also did a Principal Components Analysis to distinguish the possible different cardiac responses among the participants.
Results: The principal components analysis has distinguished three different groups, with different HRV patterns. With more years of meditation, there is a tendency towards a coupling between the breathing and the rhythms underlying the low and very low frequency ranges of heart rate variability, producing a resonant peak in the frequency spectrum.
Conclusion: We found evidences that the evolution in Zen meditation can be characterized for specific patterns of cardiac variability. The evolution is coherent as regards the years of practice until certain level. Practitioners with more than 10 years of practice show different HRV patterns. The Wavelet Transform was more effective when identifying temporal patterns of behaviour during Zen meditation, especially in more advanced practitioners. This method shows that, even in no-characteristic RSA (Respiratory Sinus Arrhythmia) range, the respiration may modulate the HRV oscillations. As in Zazen the breathing is adjusted according to the mental process (quality of attention and focus), the cardio-respiratory interactions may play a very important role to understand the HRV dynamics in Zen meditation.

EFFECTS OF AN ACHILLES TENDON VIBRATION PROGRAM ON TRICEPS SURAE FORCE PRODUCTION

LAPOLE, T., PÉROT, C.
UNIVERSITY OF PICARDIE JULES VERNE

Introduction: Many training programs exist to improve force production. In the last years, a new method based on vibration training has emerged (Luo and al., 2005). The effects of whole-body vibration are very dependant on the amplitude and frequency of the vibration, the position and the exercises made on the plate, and the intensity. To better understand the effects of vibration on muscle comportment, we propose in this study to apply vibration directly to the Achilles tendon and to analyze the effects of such a training program on triceps surae (TS) force production.
Methods: The subjects were tested before and after a 2-weeks Achilles tendon vibration program (1 hour daily, vibration frequency: 50 Hz). Maximal voluntary isometric torque was determined in plantar-flexion and then sub-maximal contractions were performed at three different torque levels (25, 50 and 75% of maximal voluntary torque). Surface electromyography was used to quantify muscle activation during efforts: activities of the soleus and gastrocnemius were summed up and rectified to give TS activation, and the activity of the antagonist, the tibialis anterior (TA), was recorded too. During contractions, twitch interpolation was used to determine an index of the deficit in TS activation. EMG – force relationships were established for each subject and the inverse of the slope of the relationship gave the neuromuscular efficiency in voluntary contractions. Another neuromuscular efficiency index was calculated as the ratio between maximal torque and maximal TS activation. A co-contraction index was calculated taking into account TS and TA activation during maximal contraction and sub-maximal contraction at 25% of maximum.

Results: After the vibration protocol, maximal voluntary isometric torque was enhanced for the 7 subjects engaged in this preliminary study. At the same time, TS EMG was enhanced and, consequently, neuromuscular efficiency (with the two counting methods) didn't change. The index of the deficit in TS activation and the co-contraction index both decreased.

Conclusion: In our study, TS force production is enhanced, which is the goal of almost every training. Gains in force may be explained by central (muscle activation) and/or peripheral (neuromuscular efficiency) adaptations (Moritani and De Vries, 1979). The vibration program was suspected to involve highly muscle spindles and to imply central adaptations more than peripheral ones: the increased maximal TS activity and the decrease in both co-contraction index and index of deficit in TS activation are in favor of such central adaptations and the constancy in neuromuscular efficiency indicates that this protocol fails to induce muscular adaptations.

To conclude, after 2 weeks of daily Achilles tendon vibration, TS force production is enhanced due, probably, to central adaptations.

BILATERAL MANIPULATION OF SHEAR MODIFIES VASCULAR ENDOTHELIAL FUNCTION

TINKEN, T.M., THIJSSEN, D.H.J., HOPKINS, N.D., BLACK, M.A., DAWSON, E.A., MINSON, C.T., NEWCOMER, S.C., LAUGHLIN, M.H., CABLE, N.T., GREEN, D.J.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: Improvement in endothelial function is associated with decreased cardiovascular risk. Shear stress is an important stimulus to arterial adaptation in response to exercise and training. We recently observed significant reverse arterial flow and shear during exercise and different patterns of shear and flow in response to different exercise interventions. However, the impact of different patterns and magnitudes of shear stress on endothelial function is not known in humans. The aim of the study was to manipulate shear stress between the limbs of healthy subjects to determine the impact on endothelial function. Methods: We examined brachial artery flow mediated dilation (FMD), an assay of nitric oxide (NO)-mediated endothelial function was assessed before and after three 30-minute interventions consisting of forearm heating, recumbent cycling and handgrip exercise. Responses were manipulated such that mean shear rates were matched between these conditions, despite each being associated with different patterns of antegrade/retrograde flow and shear. During each of these bilateral interventions, a cuff was inflated to 60 mmHg around one forearm to alter mean shear and the pattern of shear, relative to the non-cuffed arm. Results: In the non-cuffed arm, each intervention enhanced FMD% ($P<0.001$) to a similar extent ($P=0.71$). Cuffed arm mean and antegrade shear rate during exercise were lower than in the non-cuffed arm for all conditions ($P<0.05$). FMD% in the cuffed arm did not change in either the heating or handgrip conditions and decreased in the cycling trial ($P<0.05$). Discussion: These results demonstrate for the first time in humans that both the magnitude and pattern of shear stress through conduit arteries in humans have important modulating impacts on endothelial function in vivo.

EXERCISE ENHANCES WHOLE-BODY CHOLESTEROL TURNOVER IN MICE BY REDUCING CHOLESTEROL ABSORPTION AND BY STIMULATING BILE ACID SYNTHESIS

MEISSNER, M., HAVINGA, R., BOVERHOF, R., KEMA, I., KUIPERS, F.

RIJKSUNIVERSITEIT GRONINGEN

Rationale: There is a lot of information supporting a role of exercise (EX) as a preventative and therapeutic for cardiovascular diseases. While beneficial effects of EX on disturbed glucose, lipid and energy metabolism have been extensively documented, literature on the effects of EX on cholesterol metabolism is limited. Cholesterol is taken up from the diet or synthesized endogenously and can not be degraded in the body. Excess cholesterol is mainly excreted via the feces. Another major pathway for removal of cholesterol is via conversion into bile acids (BA) that eventually are lost in feces. An increased fecal BA excretion favors an increased de novo BA synthesis from cholesterol in the liver and, consequently, enhances cholesterol uptake from the circulation leading to a decreased serum cholesterol concentration.Very limited data indicate a role for EX to modulate BA metabolism in rodents. In this study, we establish the effects of EX on BA metabolism and cholesterol turnover in healthy mice.

Methods & Results: Male C57Bl6/J mice were either exposed to a voluntary running wheel for 2 wks starting at 11 wks of age (EX, n=10) or remained sedentary (SED, n=6). 48 h feces was collected at 2 wks of running wheel exposure (collected for SED at same time). Upon termination lipid profiles and hepatic and intestinal gene expression patterns were determined. Another 10 EX and 6 SED underwent a 30min gallbladder cannulation to determine bile flow and composition. EX mice had an increased feces production ($p<0.0001$), fecal BA output ($p=0.0012$), an increased fecal output of secondary BA ($p=0.02$) and increased total neutral sterol output ($p=0.0027$ vs. SED). EX induced specific changes in intestinal and hepatic gene expression patterns consistent with enhanced BA and cholesterol turnover. Paralleling the suspected increase in de novo BA synthesis to compensate for the fecal BA loss, EX had an increased biliary BA secretion ($p=0.012$). Indicating that EX increases cholesterol synthesis and decreases intestinal cholesterol absorption are the decreased plasma total plant sterol/cholesterol levels (marker of cholesterol absorption, $p=0.042$) in EX vs. SED, the increased plasma lathosterol/cholesterol levels (marker of cholesterol synthesis, $p=0.0017$) and the reduced intestinal gene expression levels of Npc1l1 ($p=0.013$), a protein required for effective cholesterol absorption.

Conclusion: EX appears to increase cholesterol and BA turnover via specific changes in the intestine that decrease intestinal BA and cholesterol absorption and hence promote their fecal excretion.The subsequent result appears to be an increased BA synthesis facilitated by an increased cholesterol synthesis to supply precursor availability for de novo BA synthesis.

Clinical Relevance: EX-induced modulations of BA and cholesterol turnover leading to reduced plasma cholesterol levels in humans might contribute to the beneficial effects of EX on cardiovascular diseases.

EFFECT OF SODIUM BICARBONATE INGESTION ON HCO3-, PH AND GASTRO-INTESTINAL SYMPTOMS

CARR, A.J., SLATER, G.J., GORE, C.J., DAWSON, B., BURKE, L.M.

AUSTRALIAN INSTITUTE OF SPORT

Sodium bicarbonate (NaHCO3) is often ingested at a dosage of 0.3g.kg-1 body mass (BM), however ingestion protocols are inconsistent (McNaughton et al., 2008). Factors confounding ergogenic benefits include using solution or capsules, the ingestion period, combining NaHCO3 with sodium citrate (Na3C6H5O7), and co-ingested food and fluid. Purpose: To quantify the effect of ingesting 0.3g.kg-1 Na-

HCO3 on blood pH, HCO3- and gastro-intestinal (GI) symptoms over the subsequent 3-h using a range of ingestion protocols, and thus to determine an optimal protocol. Methods: In a crossover design, 13 physically-active subjects undertook eight NaHCO3 ingestion and one placebo protocol. Six protocols used either NaHCO3 capsules or powder (0.3g.kg-1 BM), ingested with either 7 or 14mL.kg-1 BM low-kilojoule cordial over either 30 or 60-min. The other three protocols were i) placebo (NaCl equimolar for NaHCO3 at 0.3 g.kg-1 BM with 14 mL.kg-1 BM of fluid ingested over 30 min), ii) NaHCO3 (0.3g.kg -1 BM) and Na3C6H5O7 (0.1g.kg-1 BM) in 14mL.kg-1 BM of fluid ingested over 30 min and iii) NaHCO3 capsules co-ingested with food (1.5g CHO kg-1 BM) over 30 min with 7mL.kg-1 BM of fluid. Capillary blood was taken every 30-min and analysed for pH and [HCO3-] (Radiometer ABL725). GI symptoms were quantified every 30-min via questionnaire. Statistics used were pair wise comparisons between protocols, and the probability that differences between protocols were greater than the smallest worthwhile change (Hopkins et al. (2009). Results: HCO3- and pH were substantially greater (>75% probability) than placebo for all ingestion protocols at almost all time points. The highest value (30.9mmol.L-1) and the greatest increase in [HCO3-] (6.6mmol.L-1) was at 150 min post-ingestion for NaHCO3 capsules co–ingested over 30min with 7mL.kg-1BM fluid and the meal. This [HCO3-] was substantially greater (92% probability) than the lowest value at 150 min (28.3mmol.L-1), after ingesting 14mL.kg-1 NaHCO3-Na3C6H5O7 solution over 30 min. The peak pH (7.487) and its greatest increase from baseline (0.075) was at 120 min post-ingestion of 14mL.kg-1BM NaHCO3 solution over 60 min, and these values were substantially different (99% probability) to the lowest value (7.454) after NaHCO3-Na3C6H5O7. Overall, there were minor differences in pH and [HCO3-] between the eight protocols. The greatest incidence of GI side effects was at 90 min post-ingestion of 7mL.kg-1 NaHCO3 over 30 min, and the least side effects were for NaHCO3 co-ingested with the meal. Discussion: The changes in pH and HCO3- for the eight NaHCO3 ingestion protocols were similar, therefore an optimal protocol cannot be recommended. However, our results suggest that NaHCO3 should be ingested 120-150 min prior to exercise to induce substantial blood alkalosis, and NaHCO3 co-ingested with a high-carbohydrate meal may reduce GI symptoms.

PP-TT01 Training and Testing 1

THE EFFECT OF AMBIENT TEMPERATURE ON HEART RATE, ENERGY METABOLISM AND PERCEIVED EXERTION OF RECREATIONAL RUNNERS DURING A MODERATE TRAINING SESSION

HANAKAM, F., FERRAUTI, A., LAWRENZ, L., VENNEMANN, S., RAU, M., PLATEN, P.

RUHR UNIVERSITY OF BOCHUM, FACULTY OF SPORT SCIENCES

Recreational running is a worldwide common physical activity for an increasing number of young, middle aged and older adults. Training is usually practiced outdoor in public parks or woods, which leads to considerable differences in ambient temperature and humidity. Coaches, exercise physiologists and the sport industry recommend the monitoring of the training work load by means of heart rate. Frequently, age related formulas are used to determine an individual heart rate range which should guarantee an adaptation of performance capacity and avoid an overload stimulus.

In the present study we examined the effect of different ambient temperatures on several physiological and psychological data during a moderate run. On three experimental days interrupted by at least three days twelve male recreational runners (age: 28.9±6.2 yrs; size: 177.9±4.2 cm body mass: 76.2±5.9 kg) completed three 45 min runs on a laboratory treadmill with a constant velocity corresponding to 85 % of the 4 mmol/l threshold (v4). In a matched cross-over design the room temperature during the 1st, 2nd or 3rd experimental day was adjusted on 10°C, 20°C, or 30°C, respectively. Humidity did not differ during each temperature. Heart rate (HR), blood lactate concentration (LA), rate of perceived exertion (RPE), respiratory exchange ratio (RER) and core temperature (CT) were recorded every 9 minutes.

The following results (mean ± standard deviation) were calculated using a two factor ANOVA with repeated measurements: HR increased significantly in the course of the runs ($p<0.01$) and depended significantly ($p<0.01$) on the room temperature (after 45 min: 156±14 min-1 at 10°C, 162±15 min-1 at 20°C and 177±14 min-1 at 30 °C). A significant main effect of ambient temperature was also found for LA ($p<0.5$), RER ($p<0.5$) and RPE ($p<0.5$) pointing to higher values in the heat. Post exercise LA reached 1.27±0.52 mmol/l at 10°C ($p<0.1$ vs 20°C and 30°C), 1.67±0.44 mmol/l at 20°C and 2.20±1.15 mmol/l at 30°C, respectively. RER was significantly higher at 20°C (0.93±0.02) compared to 10°C (0.89±0.03). No rise of CT was observed during prolonged exercise at 10°C (35.9±0.54) while there was a slight increase at 20°C (36.7±0.51) and a considerable increase at 30°C (37.7±0.64, $p<0.1$). RPE remained similar during the runs at 10°C (12.7±1.4) and 20°C (13.2±1.5) but increased significantly at 30°C (15.2±2.2, $p<0.01$).

We conclude that the ambient temperature has considerable effects on cardiocirculatory, metabolic and mental responses in recreational runners. This can be mainly attributed to the increased demands on the CT regulation. A stronger activation of carbohydrate metabolism can be suspected. It cannot be recommended to use age alone for heart rate formulas for the individual monitoring of training, the ambient temperature and the training duration must also be considered.

RELATIONSHIP BETWEEN JUMPING PERFORMANCE AND RUNNING ECONOMY IN RUNNERS AND SOCCER PLAYERS

WALLNER, D., SIMI, H., HUTZ, B., HOFMANN, P.

1. FH JOANNEUM UNIV. APPL. SCI., 2. KARL-FRANZENS-UNIV. GRAZ

Muscles, tendons and ligaments are able to store and then release energy during exercise (Anderson & Pandy, 1993) and can thus reduce energy cost of running (Alexander, 1991). The elastic abilities of the ankle joint (Achilles tendon and arch of the foot) are of special importance for increasing energy efficiency during running (Ker at al. 1987). The aim of the study was to analyse the relationship between jumping performance and running economy in runners and soccer players.

Method: Male soccer players (N=11) and runners (N=9) were tested. Jumping performance was determined by means of a drop jump test (30 cm platform) and calculated based on the contact time and the following jump. The subjects tried to minimize duration of ground contact and maximize the height of the vertical jump (support of arm action).

In order to analyse running economy, subjects performed an incremental exercise test on a motor-driven treadmill. Oxygen uptake (VO2) was measured continuously and blood lactate concentration (La) was measured at rest and after every load step (increments were 0.5 km/h every minute). Running economy was defined as the oxygen consumption at 11.7 and 14.9 km/h, which represents the mean running speed at the first (vLTP1) and the second (vLTP2) lactate turn point of both groups.

Results: Mean VO2max was 55.3±3.5 ml/kg/min in runners and 54.4±3.5 ml/kg/min in soccer players with no significant differences between them ($p>0.05$). The mean running speed of soccer players and runners at LTP1 was 11.3±0.5 km/h and 12.3±0.7 km/h respectively, while at vLTP2 it was 14.3±0.7 and 15.6±0.6 km/h respectively. Significant differences were found between groups both at vLTP1 and vLTP2 ($p<0.05$).

Mean drop jumping performance was 61.3±9.8 W/kg in runners and 62.0±10.3 W/kg in soccer players with no significant difference between the two groups ($p>0.05$). Jumping performance was significantly related to oxygen consumption in runners at 11.7 km/h ($r2=0.648$; $p<0.01$) and at 14.9 km/h ($r2=0.699$; $p<0.01$), but not in the soccer players ($p>0.05$).

Discussion: The significant correlation found between jumping performance and oxygen consumption (running economy) in runners may be explained by their superior running technique compared to a more inhomogeneous technical ability in the soccer players. Only some of the soccer players were able to use the elastic properties of the ankle in the way that highly trained runners do.

Conclusion: Drop jump performance is associated with running economy in technically educated runners.

EFFECTS OF WHOLE BODY STRENGTH TRAINING ON RUNNING PERFORMANCE AND RUNNING ECONOMY IN RECREATIONAL RUNNERS

BERGERMANN, M., FERRAUTI, A.

RUHR UNIVERSITY OF BOCHUM

Millions of recreational runners worldwide are regularly participating in marathon and half-marathon competitions without being coached by professional experts. The training schedule of those persons usually consists exclusively in running. On the other hand elite long distance runners prefer more complex training methods including cross training, some aspects of running coordination as well as resistance training for trunk and leg muscles because this may improve running performance by increasing the running economy. In the present study we investigated the effects of a combined training protocol with recreational runners consisting in endurance plus additional strength training (ES) compared to exclusively running (E).

20 recreational runners (40.0±11.7 yrs; 180±9 cm; 73.7±10.8 kg) were matched into two groups (ES and E) each consisting of ten runners with identical VO2max (ES: 52.0±6.1 vs. E: 51.1±7.5 ml/min/kg) and anaerobic threshold (ES: 3.5±0.4 vs. E: 3.4±0.5 m/s). One group (ES) completed an 8-week strength training program while pursuing their usual running training. The other group (E) followed its usual running training without additional strength intervention. In ES strength training was carried out twice a week. On Tuesday the trunk muscles (reverse fly, bench press, lateral flexion, trunk extension, trunk flexion and trunk rotation) were trained (3 sets with 20 reps of the 25 RM). On Thursday a high resistance training for the leg muscles was completed (leg press, knee extension, knee flexion, hip extension and ankle extension) which aimed to an improvement of the motor recruitment patterns (4 sets with 3-5 reps of the 3-5 RM). With increasing strength weights were added to maintain the same relative resistance.

The following results (mean ± standard deviation) were calculated using a two factor ANOVA (main factors were training intervention and measurement time). No changes in body mass occurred during the intervention period. Only in ES maximum torque of knee extension (pre: 4.6±1.4; post: 6.2±1.0 Nm/kg) increased significantly ($p<0.01$). No intervention effects were found for running coordination (stride length, stride frequency and foot ground contact time). VO2 on defined moderate running velocities (v) remained unchanged in both groups. VO2max (ES: from 52.0±6.1 to 54.9±4.4; E: from 51.1±7.5 to 51.6±7.8 ml/min/kg; $p<0.05$) and velocity at the anaerobic threshold (ES: from 3.5±0.4 to 3.7±0.5; E: from 3.4±0.5 to 3.5±0.5 m/s; $p<0.01$) increased significantly in both groups, while no significant intervention x measurement effect was found.

Results suggest that running economy defined as lower O2-uptake at a given speed is not affected by strength training under the conditions of our study unless a clear improvement of isometric strength in the leg muscles was found. Nevertheless, the overall running performance and the VO2max were clearly improved especially in ES, which point to a better oxidative capacity induced by strength training.

CHILDREN TOLERATE INTENSIVE INTERMITTENT EXERCISE BETTER THAN ADULTS

MÜLLER, J., ENGEL, F., FERRAUTI, A.

RUHR UNIVERSITY OF BOCHUM

In exercise science literature a decreased capacity as well as a strongly reduced efficiency of the anaerobic metabolic pathway is awarded in children. The benefit and value of health of anaerobic training are questioned explicitly. Therefore the recommendations for endurance training with children in young age are usually focused on aerobic activities. In contradiction to this, an analysis of the self chosen leisure time movement patterns show that children prefer intermittent, explosive and intensive activities of very short duration.

The aim of this study was to investigate how children and adults tolerate short intensive and intermittent anaerobic demands. 22 trained children (C) (13 girls: 10.6±1.4 yrs; 152±8 cm; 41.5±9.1 kg; muscle mass 22.1±4.4 kg; 9 boys: 9.7±1.1 yrs; 143±6 cm; 34.5±4.4 kg; muscle mass 18.8±2.3 kg) and 26 athletic trained adults (A) (12 women: 22.5±2.2 yrs, 169±4 cm, 58.0±4.1 kg, muscle mass 34.4±2.8 kg; 14 men: 23.0±2.4 yrs, 181±6 cm, 72.5±7.3 kg, muscle mass 45.6±4.2 kg) participated in the study.

All athletes completed an identical intermittent sprint running protocol on an indoor track followed by an active (slow jogging) 30 min recovery. The protocol consisted of ten maximum 5 s sprints with a 40 s rest in between (2 min rest after 5 sprints). We recorded heart

rate (HR), rate of perceived exertion (RPE) and 15m time (t 15) of each sprint as well as blood lactate concentration (LA) and blood pH (pH) pre-exercise, after 5 and 10 sprints (s 10) and during the post exercise recovery.

The following results (mean ± standard deviation) were calculated using a multi factor ANOVA (main factors were age, sex and measurement time). Maximum LA and RPE were significantly lower ($p<0.01$) in children (LA 5.58±2.87 mmol/l, RPE 10.8±2.4) compared to adults (LA 10.02±3.07 mmol/l, RPE 16.7±1.8). Blood pH remained significantly higher ($p<0.01$) in children (pHs10 7.38±0.07) than in adults (pHs10 7.29±0.09). At similar sub maximum LA (6 mmol/l) pH remained higher in children. During recovery, the half time to reach a physiological LA was significantly shorter ($p<0.01$) in children (7.3±2.5 min) compared to adults (10.8±3.7 min). There was no significant difference in decrease of t 15 (t15 max – t15 min) between children and adults. A significant main effect of sex was only found for t 15m.

We conclude that anaerobic intermittent exercises can be considered in athletic training with prepuberal children without any risk of a metabolic or psychological overload. The striking pH stability and the quicker recovery of the children point to an overall better regulated acid-base balance. Several recommendations in exercise science literature cannot be justified under consideration of our data.

EFFECTS OF 3 DAYS TRAINING WITH HYPEROXIA ON METABOLISM AND SYSTEMIC CIRCULATION

WANG, Y.C., SMITH, R.S., JANG, J.T.

NATIONAL TAIWAN SPORT UNIVERSITY

Introduction: Mankind's dreams of running faster on the track have lead sports scientists and coaches to work together to refine the athletes peaking cycle. In this study we looked at the 400m run which is a combination of speed and endurance. Therefore, the aim of this study was to design a training protocol consisted of 3 days training with hyperoxia on the treadmill. The goal was to enhance the athlete's performance by altering the metabolism and systemic circulation.

Methods: Training consisted of 3 days training on the treadmill under hyperoxic conditions. Six 400m male track specialist. The research test consisted of a 400m performance (pre - post test). Training tests were separated into day 1 (Tr-1) and day 3 (Tr-3) and represented the intermittent mode, and day 2 (Tr-2) represented continuous running. Intermittent workload Tr-1 and Tr-3 was set at 90 % of the subject's best time for (3x3x90 %); continuous running was sustained at 50 % performed on Tr-2.

Results: Results indicated five of the six subjects significantly increased their 400m speed 0.05-0.15 m/s. Only one subject showed no improvement (-0.19 m/s). In the two interval training sessions' (Tr-1, Tr-3) blood lactate concentration indicated a downward trend post test and in the 6th interval, and NH3 in 6th interval training and in the 3rd min of rest (E3) decreased significantly ($p <.05$). Free radicals(H2O2) indicated no significant change ($p>.05$). While looking at heart rate during interval training, Tr-1 and Tr-3 indicated a downward trend.

Discussion: In this study, lactic acid and NH3 showed a downward trend (Tr-1 vs. Tr-3 & T-1 vs. T-2), under high-intensity exercise with hyperoxia, that PCr (phosphocreatine) have diminished its efficiency (stellingwerff et al., 2006) and relative lower production of blood lactate (Hollmann et al., 2002). In this study H2O2 indicated no significant change which was different from Cooper et al (2002) findings. This could possibly be caused by antioxidants (Muna et al., 2001) and HSP70 (Kinnunen et al., 2005) but in order to better understand this further research would need to be conducted. Heart rate in Tr-3 were lower than Tr-1 but it weren't significant. In 400m speed performance were not significantly improved. These indicated that further time to adapt is required.

HIGH DOSE MAGNESIUM SUPPLEMENTATION EFFECTS ON 400M SPRINT PERFORMANCE AND METABOLISM

CHEN, C.H., SMITH, R.W., JANG, J.T.

NATIONAL TAIWAN SPORT UNIVERSITY

Introduction: Matwejews (1972) proposed the sports training 'period' he divided it into preparation periods (Ⅰ,Ⅱ), specific training periods (Ⅰ,Ⅱ), and a competition period. This type of process allow athlete to reach their best physical condition in specific period Ⅱ and maintain it through the competition period. It is still unclear whether other training methods can push the athlete to breakthrough through to new levels of peak performance. Therefore, the aim of this study was to observe the effects of short term and high doses magnesium supplementation before high intensity interval training on performance and metabolism for 400 m runners

Methods: Two tests were investigated in this study. The first was 400m test (pre and post test), the second was a training test (the 1st and 3rd day). The training program consisted of a high intermittent mode on the 1st and 3rd day and a continuous run on the 2nd day. The intermittent and continuous workload were set 90% (3x3x20s)and 50% (15min)of the individuals best performance time; each athlete took 400 mg magnesium with 200ml water and warmed up for 30mins before each of the three days of training sessions.

Results: During the training test (Tr-1 and Tr-3), blood lactate and NH3 concentrations decreased after Tr-3 ($p>.05$). During the 400m test, three subjects improved their range of speed performance by 0.01-1.80 s posttest; two subjects increased their range of speed performance by 0.21 and 0.54 s. Only one subject showed no increase in range of speed performance but still maintained pretest Results: Discussion: During the training test, blood lactate concentration and NH3 were decreased. Lukaski(1983)explained blood lactate concentration decreased by saying that magnesium stimulates the two-phosphoglycerate (2, 3-diphosphoglycerate, 2, 3-DPG) enzymes, while increasing red blood cells to release oxygen to work the application of muscle tissue. Bertschat et al.(1986)study indicated when looking at marathoners who supplemented with magnesium showed a significant reduction in competition protein degradation, and NH3 generated reduced. Hypothetically speaking, this may be due to the reduction of neonatal sugar resulting in a reducted its metabolites NH3, in addition to magnesium and is also involved in cell ammonia (ammonia) to eliminate an important enzyme. Golf et al.(1998) pointed out that triathlon competitors after four weeks of added magnesium reduced their race times. Comparison to this study only three subjects improved their 400m results, this may be due to the supplement ingestion time being only 3 days.

CARDIORESPIRATORY AND METABOLIC CHANGES DURING AND AFTER THREE DIFFERENT MODES OF EXERCISE

MANDROUKAS, A., HELLER, J., METAXAS T., PAPAVASILIOU, A., RIGANAS, C., KARAGIANNIS, V., KOTOGLOU, K., CHRISTOULAS, K., MANDROUKAS, K.

ARISTOTLE UNIVERSITY OF THESSALONIKI

Introduction: Reliable experimental forms are essential to gain insight into the cardiorespiratory and metabolic mechanisms underlying the effectiveness of training in different modes of exercise. The purpose of this study was to examine the cardiorespiratory and metabolic variations during exercise and passive recovery time (PRT) among three forms of exercise, namely active recovery (AR), passive recovery (PR) and continuous running (CR) in physically active male adults.

Methods

Fifteen physical education male students with subspecialty in soccer were studied (mean age 22.3±2.5yrs and years of training 12.3±2.5yrs). All participants performed a graded maximal test on a treadmill for the determination of VO2max using an open–circuit ergospirometric via breath–by–breath gas analyzer system. The AR exercise protocol consisted of running on a treadmill for 4min at 12km/h-1 followed by 4min at 8km/h-1. This was repeated four times and the exercise time was 32min. The PR protocol consisted of four bouts of 4min running at 12km/h-1 followed by 4min of rest in between bouts for a time of 32min. CR was also performed on a treadmill at a speed of 12km/h-1 without gradient. The running time was 32min. Blood lactate (BLa) measurement was carried out using capillary blood taken from a fingertip at 8, 16, 24 and 32 min of exercise, as well as at 10, 20 and 30 min of PRT after the end of exercise protocols.

Results: At the running speed of 12km/h, HR and VO2 did not differ among AR, PR and CR protocols in bouts 1 and 2. However, in bouts 3 and 4, HR and VO2 were significantly higher in CR compared to AR and PR ($p<.05$, $p<.01$). During the 4th bout the VO2 was in AR 82%, in PR 79% and in CR 100% of VO2max. In all bouts at 8km/h the HR and VO2 were found to be significantly higher in AR compared to PR ($p<.001$). BLa reached the highest values in the first 8min of exercise in all three protocols and was significantly higher in PR compared to AR ($p<.05$). At completion of exercise BLa values were significantly higher in CR compared to the values of AR and PR, respectively ($p<.001$). Ten and 30min after the end of exercise in PRT, BLa values were significantly higher in CR compared to AR and PR ($p<.001$). No significant differences in BLa values between AR and PR in PRT were found.

Discussion: The results of this study showed that HR and VO2 in all types of exercise gradually increased along with the muscle effort. Therefore, it was found that there is greater load in the cardiorespiratory and metabolic system with CR than AR and PR. The low BLa values that was found during AR may be due to its reduced muscle concentration and to its increased clearance from blood. In conclusion our study shows that during CR the cardiorespiratory system can be fully loaded without high BLa concentration in comparisons to the values that appeared during the first test for determination of VO2max.

PREDICTION EQUATION TO ESTIMATE VO2MAX IN BRAZILIAN YOUNGSTERS FROM A RUNNING PERFORMANCE TEST IN 1600M.

ALMEIDA, J., SANTANA, H.A.P., PARDONO, E., SOTERO, R.C., SALES, M.M., SIMÕES H.G.

CATHOLIC UNIVERSITY OF BRASILIA (UCB)

Introduction: VO2max is considered a physiological parameter that evaluates functional capacity level of cardiorespiratory system and aerobic power (Basset and Howley, 1997), as well to physical training prescription (Billat et al., 1999). To estimate VO2max through equation represents a cheaper possibility and a larger practical application for a field test (Basset and Howley, 2000). Therefore, the aim of this study is to suggest a predictive equation for brazilians from 1600m running performance.

Methods: Took part on this study 30 physically active brazilians youngsters men (23±3.1yrs; 74.8±5.8kg; 1.78±0.05cm; 49.8±6.5ml.kg-¹.min-1) that were submitted to an incremental exercise test (IT) on treadmill until exhaustion with gas analysis. Subjects also performed a 1600-m running track as fast as possible. Then the volunteers were randomly allocated in two groups: G1 – to generate a specific predictive equation for VO2max, and G2 – to apply predictive equation to evaluate their validity on estimating VO2max in a Brazilian population sample.

Results: The relationship between the VO2max on IT and the running velocity on 1600-m as obtained for G1 resulted in the following predictive equation: VO2max=0.177ּ1600Vm + 8.101. When such new equation was applied on participants of G2, the predicted VO2max (50.1±7.2ml.kg-¹.min-¹) did not differ from VO2max determined directly on IT (50.1±7.1ml.kg-¹.min-¹) with a high correlation between them (r=0.81).

Discussion: The determination of VO2max, even when evaluated in indirect form, allows to evaluate cardiorespiratory fitness and to presume risk development of chronic illness pathologies (Moreira, 2007). The importance of predictions equations consists in the possibility to evaluate a large number of persons from a fast, non-invasive, low cost and practical way. Therefore, the predictive equation proposed on present study was considered valid for this purpose through the 1600-m running performance for our participants.

PECULIARITY OF THE O2 DELIVERY- O2 UTILISATION SYSTEM IN MIDDLE DISTANCE RUNNERS: CORRELATION WITH PERFORMANCE

FERRI, A., ADAMO, S., LA TORRE, A., MARZORATI, M., DANZI, S., MISEROCCHI, G.

UNIVERSITY OF MILANO-BICOCCA

Introduction. Many studies conducted since the 1970s have investigated the particular physiologic characteristics of middle-distance athletes. Several authors (1,2) have focused on physiological parameters, such as maximal oxygen consumption, VO2max and velocity at VO2max (Vmax), that may determine/predict performance. However, at the moment there is no consensus. Our purpose was to evaluate

additional physiological parameters (VO2 kinetics, maximal capacity of muscle O2 extraction, presence of a slow component of VO2 and Delta[deoxy(Hb+Mb)], lactate concentration, time to exhaustion) that may better predict performance in an homogeneous group of international level middle-distance (1500m) runners (n=8).

Methods. After an incremental exercise (IE) to voluntary exhaustion on a treadmill, to evaluate peak VO2 and the ventilatory threshold (VT), athletes carried out two, 6-min, constant-load exercise tests below VT (<VT) and two constant-load exercise to exhaustion at the maximal velocity reached during IE. The test were performed on three different days. Pulmonary VO2, VCO2 and ventilation (VE) were determined breath-by-breath. Vastus lateralis oxygenation was determined by near-infrared spectroscopy (NIRS) and changes in deoxygenated hemoglobin+myoglobin concentration Delta[deoxy(Hb+Mb)] were taken as a muscle oxygenation index. A blood sample from ear lobe was also taken at baseline and at the end of each exercise, to evaluate the blood lactate concentration. The data were analyzed by correlation procedures and stepwise regression analysis.

Results. In contrast to previous research, we did not find a significant correlation between VO2peak and 1500-m velocity (r=0.057, non significant); the correlation between Vmax and 1500-m velocity approached significance (r=0.63, p=0.09). The only parameters that were significantly (p<0.5) correlated with the 1500-m velocity were the maximal capacity of O2 extraction (r=0.78) and the amplitude of the slow component of Delta[deoxy(Hb+Mb)] (r=0.74). All of the other parameters measured were not correlated with 1500-m performance.

Discussion. These results suggest that the best predictors of 1500-m velocity were related to the capacity of the muscle to extract O2, a peripheral parameter which reflects the muscle's capacity for oxidative metabolism (dependent on the number and quality of mitochondria, capillarisation, etc.). The relationship between the slow component of Delta[deoxy(Hb+Mb)] and 1500-m velocity can possibly be attributed to the Bohr effect, i.e. a greater increase in lactate by the better performing athletes may provoke a greater release of O2 from the hemoglobin and a subsequent improved aerobic efficiency of the muscle. Further research is required to better understand how to improve the capacity of the muscle to extract O2.

THE EFFECT OF VO2MAX PERCENT UTILIZATION AT 5KM COMPETITION AMONG ELITE DISTANCE RUNNERS

STØA, E.M., STØREN, Ø., ENOKSEN, E., INGJER, F.

TELEMARK UNIVERSITY COLLEGE; NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: The aim of the present study was to explore to what extent maximum oxygen uptake (VO2max) and fractional utilization (% VO2max) in 5km competition speed correlate with 5km performance times among long distance runners at a national level, and to investigate if there is a significant difference between VO2max and %VO2max at 5km competition speed. Methods: Eight elite long distance runners with 5km performance times of 15.10 minutes (± 32 sec) were tested for VO2max during an incremental protocol and for % VO2max during an eight minute treadmill test at the velocity representing their 5km seasonal best performance time. In all cases, P≤0.05 was taken as the level of significance in two-tailed tests. Descriptive statistical analysis was made to display means and standard deviations (SD). To compare means, paired T-tests and independent samples T-tests were used. The data were tested for normal distribution using Quantile-Quantile (QQ) plots. Correlations were calculated by the Pearson correlation test. Results: The subjects average VO2max was 73 (±4.7) ml∙kg-1∙min-1 and 207.9 (±14) ml∙kg-0.75∙min-1. The results showed a strong correlation between performance and VO2max (R2 = 0.752 and 0.684 respectively). The average O2 expenditure of the subjects competition speed was 71.5 ml∙kg-1∙min-1 and 203.8 ml∙kg-1∙min-0.75. The mean values for VO2max was 73.1 ml∙kg-1∙min-1 and 207.9 ml∙kg-1∙min-0.75, which gives an average of 97.3 and 98 %VO2max. The results showed no correlation between fractional utilization and 5km performance. There was no significant difference between VO2max and the O2 expenditure during 8 minutes of running at the runners individual 5km competition speed. Discussion: Since %VO2max did not correlate with performance in this study, the differences in performance level among the runners must be due to another factor than the fractional utilization. Most likely, the better performance is a result from a higher VO2maks and/or a better running economy. To improve 5km performance time, the runner should focus on high intensity aerobic interval training (1) and maximal strength training (2). When improving VO2max and RE, the runner will run faster, and consequently utilize a higher percentage of VO2max during competition. Conclusion: The major finding in this study is that fractional utilization (%VO2max) does not correlate with 5km performance among elite distance runners. Training aiming to increase %VO2max may thus be of little or no importance in performance enhancement for competitions lasting up to approximately 20 min.

PP-TT02 Training and Testing 2

LACTATE MINIMUM TEST PROVIDES A GOOD ESTIMATE OF THE MLSS RUNNING SPEED

SANCHEZ-MEDINA, L., GARCIA-PALLARES, J.

UNIVERSITY PABLO DE OLAVIDE, SEVILLE

Introduction: To individually determine an exercise intensity which demarks the aerobic-anaerobic transition is of great practical interest, having been the focus of research for decades. The maximal lactate steady state (MLSS) is defined as the highest blood lactate concentration that can be maintained over time without continual lactate accumulation (Beneke, 1995; Billat et al., 2003). However, the classical MLSS protocol, considered by many as the gold standard in anaerobic threshold (AT) assessment, is tedious and time consuming. The

original LMT (Tegtbur et al., 1993) was develop to assess the maximal exercise intensity at which an equilibrium exists between the production and removal of lactate. Although not universally accepted, the LMT is an attractive test believed capable to estimate, in a single session, the individual AT. Nevertheless, contradictory results have arisen from research (Bacon and Kern, 1999; Jones and Doust, 1998). The aim of this study was to assess the validity of the LMT for the estimation of the MLSS.

Methods: Twenty male runners (mean[SD]: age 29.8[6.3] yr, height 1.75[0.05] m, weight 67.4[6.6] kg, VO2max 58.2[5.8] ml/kg/min) underwent a battery of running field tests within 4 weeks: Université de Montréal Track Test for the determination of maximal aerobic speed (MAS), LMT, and several constant-speed runs of 30-min duration each performed on different days for the precise determination (+/-0.25 km/h) of the MLSS velocity (MLSSv). Four different methods (visual inspection, 2nd order polynomial fit, 3rd order polynomial fit and cubic-spline fit) used to individually determine the lactate minimum speed (Vmin) were compared.

Results: MLSSv and Vmin were highly correlated (r=0.80-0.87 for the three mathematical methods employed) although mean Vmin (quadratic fit method) was significantly lower ($p<0.05$) than MLSSv (14.8[0.9] vs 15.1[1.2] km/h). Heart rate and rate of perceived exertion at Vmin and MLSSv were not significantly different. Blood lactate concentration at MLSS was 4.7[1.6] mmol/L, showed great variability between subjects (CV=35%), and was independent of performance.

Discussion: These results suggest that the LMT gives a good estimation of the MLSS running speed and can be considered a valid instrument for the field evaluation of runners. Of the three methods employed, quadratic fit seemed superior (r=0.87; $p<0.01$; SEE=0.52). A proposal is made for performing the two initial sprints of the LMT at 130% of MAS and the first stage of the incremental part of the test at 70% of MAS, something not specified in the original protocol but that has proved to be a valuable addition.

NON FUNCTIONAL OVERREACHING DETECTED BY AN ONLINE TRAINING DIARY: A CASE STUDY

PIACENTINI, M.F., MINGANTI, C., CAPRANICA, L., MEEUSEN, R.

UNIVERSITY OF ROME-FORO ITALICO

Functional overreaching is defined as short term performace decrement without severe negative psychological or physiological symptoms. When the imbalance between training and recovery continues, non functional overreaching (NFOR) may occur. The distinction between NFOR and Overtraining syndrome (OTS) is very narrow, and occurs mostly on exclusion criteria (Meeusen et al. 2006). Although many markers have been proven to identify OTS, prevention remains the most important issue and training diaries with subjective perception of fatigue have been proven to be useful (Piacentini et al 2008). The purpose of the present study was to evaluate psychological, training diary data and blood analysis in an athlete with NFOR.

Methods: A female marathon runner (30 yrs) was followed for 2 years by means of a daily online training diary (BLITS®), a weekly POMS, monthly blood analysis. She filled in the task and Ego Orientation in Sport questionnaire (TEOSQ Duda 1989). In one year she ran 6 marathons. The last 2 ran 3 weeks apart were prepared doubling training volume and she was diagnosed as NFOR.

The training diary consists of 3 pages that include both objective and subjective data (muscle soreness, physical and mental well-being, training intensity and attractiveness) reported on a 10 cm visual analogue scale (VAS). Furthermore, parameters that quantify and summarize training and adaptation to training were calculated, such as training load (training intensity VASxduration), monotony of training (day by day variability in training), and the overall strain (Load x monotony). Moreover, we calculated a parameter (BLITS formula) that takes into account the subjective parameters collected from the diary: time x intensity x attractiveness x muscle soreness x mental well being

RESULTS: Tha data analysed regard the period november-december 2007 when the athlete was diagnosed as NFOR. Her POMS data showed a significant increase in fatigue, depression and decrease in vigour. Blood analysis showed anemia with a 14% decrease in red blood cells, a 30% decrease in hemoglobin, and a 25% decrease in hematocrit and she reported interrumption of her menstrual cycle. Results from the training diary show a 1617% increase in the BLITS formula data during the NFOR period while only an 86% increase in strain. All parameters restored after 3 months. Her TEOSQ shows that she is more task (3,8) than ego (3,16) oriented.

DISCUSSION: The results demonstrate that prior to performance decrements (marathon race perfomance) due to excessive load (given also by her high task orientation), training diary parameters detected with the BLITS formula are the most visible predictors of extreme fatigue, and strongly correlated with negative mood. Therefore, the use of the online training diary seems a valuble tool for training monitoring and prevention of OTS

HEART RATE DISTRIBUTION IN MASTER ENDURANCE RUNNERS DURING A HALF-MARATHON

FERRAGINA, A., AMMENDOLIA, A., MINGANTI, C., CAPRANICA, L., PIACENTINI, M.F.

1. UNIVERSITY OF MAGNA GRÆCIA, CATANZARO, 2. UNIVERSITY OF ROME FORO ITALICO, DEPARTMENT OF HUMAN MOVEMENT AND SPORT SCIENCE

Introduction: Runners above 35 years of age that compete and train regularly are catalogued as Master athletes. But unlike professional or elite athletes, master athletes do not have the same technical support in terms of training and recovery (1) (2). Master athletes infact have to train between very busy schedules due to work or family duties, nevertheless some are able to reach pretty important results. The aim of this study was to determine heart rate and the rating of perceived effort (RPE) during a half-marathon (21 Km) competition

Methods: Five master runners, which regurarly train for endurance events, (age:.47,2 ±7 yrs; weight. 60 ±9,5 kg; height. 169±6 cm; bmi 20.78 ±2.0) competed in the master half-marathon regional championship (performance time 1h 26' 28" ± 4'30"). Their heart rate was monitored every five seconds with a heart rate monitor Accured plus (Polar Electro, Finland) (3) and RPE was measured using both the

Borg's scale (4) and a Visual Analogue Scale (VAS) at 30' after the end of competition. The maximun heart rate was determined using Tanaka's formula (208 - 0.7*age). Mean, standard deviation and Spearman's correlation were used for data analysis

Results: Mean RPE using Borg's scale (4.8 ±1.6) was strongly correlated with VAS (68 ±8) (r=0,87)

HR expressed as percent HRmax showed very high values throughout the whole race, with a uniform trend: 1st quarter 90.7 ±6.2 %(157.8 bpm ±14.4); 2nd quarter 93.3 ±6.0% (162.0 bpm ±7.2); 3rd quarter 95.8 ±4.8 %(166.5 bpm ±7.0); 4th quarter 98.1 ±6.2% (170.7 bpm ±13.3) (fig.2). The performance of the present competition was 93.9% ±3.2 of their personal best (1h 21' 01" ± 2'08")

Discussion: Athletes that are trained to perceive their fatigue can use either scale, or VAS or the Borg scale that were strongly correlated. However, the perception of fatigue data do not correlate with the HR measured during competition that was always above 90% of their HRmax. At the moment the athletes are asked to answer to the two different scales, most probably the sensation of fatigue is strongly reduced also by the satisfaction of a positive result and does not reflect the real fatigue they were actually feeling during competition.

COMPARISON OF PHOTOCELL AND OPTOJUMP MEASUREMENTS OF MAXIMAL RUNNING VELOCITY

DOLENEC, A., COH, M.

UNIVERSITY OF LJUBLJANA, FACULYT OF SPORT

Due to additional data on the stride length, the contact and flight times, a combination of photocells and optojump (OJ) measurements are lately being used to measure running velocity. As both systems are used to measure velocity, this research focused to ascertain whether velocity measurement results obtained by either photocells or by OJ are the equivalent.

The research involved 17 sprinters (11 male and 6 female). Their average best score in a 100 m run was 11.24 s (+-0.56), the age 19.9 years (+-3.4), height 1.74 m (+- 7.4), weight 65.6 kg (+-7.57). Each of them performed two sprints of 20 meters, flying start. For further analysis, the fastest sprint measured with the photocells was used. The velocity was simultaneously measured by the photocells (Brower timing, USA) and OJ (Microgate, Italy). The photocells were installed at four consecutive, 5 meters long sections. Photocells were installed at a 1.14 meter height. The OJ was installed from the first to the last pair of photocells. In measurements with OJ, foot contact closest to the photocells was used to determine the beginning and the end of an individual section. A t-test for related samples was used to compare the variables measured by photocells and by OJ. The ANOVA test was used to test the differences among the variables that were measured with the same method.

In measurements with photocells, the running velocity on the 10- to 15-meter section was 10% higher than the running velocity on 0- to 5-meter section. On the 0- to 5-meter section, the measured velocity was statistically significantly lower than the velocities measured on other sections. In OJ measurements, there were no statistically significant oscillations in velocities as per individual sections. Velocities measured with photocells and OJ statistically significant differed on two sections. The velocity measured with photocells on the 0- to 5-metre section was statistically significantly lower than the velocity measured with OJ. While on the 10- to 15-meter sections, the situation was just the opposite. Regardless of the section length (5, 10, 15, or 20 m), the average speed measured with the photocells was always statistically significantly lower than the average velocity measured with OJ.

The results of maximal velocity measurements with single beam photocells installed 1.14 meters high cannot be compared to results of maximal velocity measurement done by OJ in cases when the measurement sections are 5 to 20 meters long. Further researches should be carried out in order to ascertain which of the timing system gives the results that would be closer to the actual centre of mass velocity.

CREATINE KINASE MONITORING AND PERFORMANCE DURING 3 WEEKS OF HIGH ALTITUDE TRAINING IN ELITE MIDDLE AND LONG DISTANCE RUNNERS

SPERLICH, B., ACHTZEHN, S., DE MAREES, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Creatine kinase (CK) is a highly sensitive marker for muscle damage. It is well known that a wide range of exercise modalities such as high-intensity, volume training, and especially weight-bearing eccentric exercise cause the greatest rises in CK. Usually peak values are seen 24-48 hour after such exercise. Therefore a daily monitoring of CK and other exercise relevant strain markers could facilitate coaches in controlling training load. Especially, middle and long distance runners perform training camps in order to increase performance. Within these, training volume and/or intensity increases considerably compared to "normal" training procedures. Until today no clear consensus exists on which threshold of CK elevation correlates with changes in performance as well as other monitoring parameters.

METHOD: 9 (2 female) highly trained middle and long distance runners from the German National Track and Field team were monitored daily during a training camp at 2100m altitude. Values for CK, resting heart rate (HR) and body weight (BW) were collected in the morning hours between 7AM and 9AM. Additionally all athletes had to rate their overall body perception (BP) and quality of sleep (QS) on a six point scale (1=very good, 6=very poor). Running speed (V3) at 3 mmol/l blood lactate was assessed before and after the training camp. All middle and long distance runners performed the same amount of training session. Each athletes performed two to three training session per day. One day with less training volume and intensity was set after 3-5 consecutive days depending on training advancement. Training intensity was controlled by heart rate, lactate values as well as CK and perceptual values. One-two days of degraded BP and QS accompanied by elevated CK resulted in a reduction of intensity or training volume.

RESULT: V3 increase form 4.4±0.2 pre to 4.6±0.2. Baseline values for CK in mean were 163.1±43.8 U/L ranging from 96-241U/L. Highest values during the three weeks were found at day 17 of 20 ranging from 233 to 679 U/L. Mean CK Values for all athletes in three weeks was 346.5±146.5 U/L. The individual CK kinetics over the complete period of time revealed individuals with generally lower CK values 223 vs. individuals with considerably higher CK values (501 U/L) but same work load. Despite clear mean increase in CK body

weight remained unchanged from pre to post (66.7±10.6 vs 66.6±10.3kg). Mean SQ decreased by 0.5 points towards the end of the camp. Mean BP remained unaltered.

Summary: The results demonstrate low as well as high individual CK values despite equal work load. In this study mean CK values of 346.5±146.5 U/L over three weeks did not affect performance enhancement negatively. In several cases elevated CK kinetics correlated with degraded BP and QS. BW remained unaltered. The results in this study confirm the necessity to perform individual profiles of different markers in order control training over time.

SIMULATED ANALYSIS OF THE RELATIONSHIP BETWEEN TRAINING AND PERFORMANCE IN CYCLING

PFEIFFER, M., SCHROT, C.

UNIVERSITY OF BAYREUTH

Introduction: A model to investigate adaptive processes by means of antagonistic dynamics has been developed by Perl (2001). The PerformancePotential-Model (PerPot) helps to simulate the relationship between training and performance by using a state-event-model with adaptive delays. Due to the fact that training influences the delay of physiological responses, the PerPot software allows the determination of model parameters by constant (global) or varying delay parameters (local). We intend to determine whether PerPot can be used to validly analyse adaptations to training in elite cyclists (preparation period). Two different variables for training and performance were tested. Beyond that we used local delays to identify periods of different adaptation chronology.

Methods: Two road cyclists (S1, professional, 30,000km/year; S2, elite, 22,000 km/year) and one mountain biker (S3, elite, 13hrs/wk) collaborated voluntarily in our 5-month study. The training stimulus (input) was quantified daily by heart rate (TRIMP, Millet et al., 2002) and power output (P, Watt) (SRM-System). Performance (output) was determined three times weekly by cycle ergometer tests: an incremental exercise test to exhaustion (IET, kJ/kg) and a 10sec-Wingate-Test (WT, Watt). Additional physiological parameters (urea, creatine kinase, haematocrit, HRV) were measured before each testing. Intraclass Correlation Coefficient (ICC) between modeled and real performances was calculated to estimate model validity (model fit).

Results: An acceptable model fit (ICC) with global delay parameters for input TRIMP as well as P could only be achieved for S1 (TRIMP to IET/WT: S1 = .93/.76, S2 = .58/.38, S3 = .36/.18; P to IET/WT: S1 = .89/.56, S2 = .42/.42, S3 = .53/.16). A better model fit was achieved for IET than for WT, whereas no evidence for the benefit of either input alternative was found. With local delay parameters, we identified 3 to 5 adaptation periods. Afterwards the PerPot was fitted by using the subdivided datasets, whereby an excellent model fit (ICC) was achieved for both TRIMP (M = .86, SD = .14, range = .61 - .97) and P (M = .84, SD = .13, range = .63 - .98).

Discussion: The results confirm that long-term adaptation is characterised by phases of different time delay, so that a time varying model is useful for analysing training effects (Busso et al., 1997). The progression of the physiological parameters provides indications of the course of delay variation.

EXERCISE INTENSITY DURING A 700KM ONE LEG OFF-ROAD BIKING RACE

WEYDAHL, A., CALOGUIRI, G.

FINNMARK UNIVERSITY COLLEGE, UNIVERSITY OF MILAN

The purpose of this descriptive study was to examine the exercise intensity of a continuous 700km off-road biking competition with a total of about 10,000 climbing meters across the Finnmark plateau in Norway. The race takes the bikers through cart roads and single-track paths. In some places, the bikers need to get across wild, pathless terrain, where technical challenges are frequent and the bikes often need to be carried. The competitors need to cross hundreds of brooks, creeks and a few large rivers. The race goes through twelve checkpoints 60-99 km apart (about 3 to 10 hours), lasting close to 5days. During the race there are three compulsory stops, each at a minimum of 2 hrs. The race is a team race, with two or three bikers in the team. Five male bikers 22-54 years old (mean age 40 years) volunteered to participate in the study during the 2008 test race.

Within a week before and after the race their anaerobic threshold (AT), maximal oxygen consumption (VO2max) and maximal heart rate (HRmax) were measured using a Lode Excalibur sport ergobike with a preferred cadence around 90 rpm. The bikers wore Polar ® HR belt and watches from testing until about 48 hrs after end of race. HR limits for the five intensity zones (Z) based upon the individual HRmax used by the Norwegian Olympic Committee were calculated for each biker: Z1:55.1 -72 % HRmax; Z2:72.1-82% HRmax; Z3:82.1-87% HRmax; Z4: 87.1-92% HRmax; Z5:92.1-97% HRmax. The times in minutes and as percent of total individual race time with HR in each intensity zone between each checkpoint (leg) were calculated for each biker. The average HR absolute value and as percent of HRmax on each leg were also calculated.

The bikers had an average VO2 max 73.3 ml/min x kg (65.2-82.4) before the race. Three bikers finished, two had to quit after finishing 60% of the race because of injuries. During most of the time during biking the bikers worked with HR intensity zone 1. One biker had periods in HR zone 3 during five of the eleven legs, the other bikers worked only in HR zone 3 during the first, fifth and the last leg. Two of the bikers had recorded HR in HR zone 4 for a maximum of 15 min during the race. None of the bikers worked in HR zone 5 during the race. The HR on the first leg (76.5km) showed the highest average value 70.9 %HRmax (74.3 %HRmax - 67.2 % HRmax) for all five bikers. The lowest average HR value for 3 of 4 bikers was on the 28.1 km long 8th leg (52.8 %HRmax – 55.1 %HRmax), while one biker had his lowest average HR on the 47.3km long 10th leg (58.6 %HRmax).

This study shows that this continuous off-road race is physically very demanding.

COMPARISON OF EXCESS POST-EXERCISE OXYGEN CONSUMPTION AFTER THIRTY MINUTES OF CYCLING AND CROSS-TRAINING EXERCISES

GALVANI, C., ANNONI, I., ZAPELLI, E., RICCI, G., CASOLO, F., FAINA, M.

CATHOLIC UNIVERSITY

Introduction: In the recovery period after exercise there is an increase in oxygen uptake termed excess post-exercise oxygen consumption (EPOC). The magnitude of EPOC after aerobic exercise may depend on duration and intensity of exercise, on type of exercise (split exercise or continuous sessions) and on training status and sex. It is not clear whether various modes of aerobic exercise affect EPOC differently (Børsheim, 2003). Cycling exercise (CE) has been compared with treadmill and arm crank exercise separately but the impact of cross-training exercise (CTE) on EPOC has not yet been examined. The aim of this study was to evaluate the acute effects of moderate intensity CE and CTE on EPOC.

Methods: 6 young moderately active female (age, 24,2±0,8 yr; BMI, 21,5±2,4 kg/m2; RMR, 1288±78,2 kcal/day) participated in the study over a 2-week period. In the first week subjects filled a Baecke questionnaire of habitual physical activity, undergone a resting metabolic rate (RMR) measurement and 3 incremental tests to exhaustion (V'O2peak at treadmill, cycle ergometer and arm ergometer). In the second week they completed two bouts of 30 min of exercise at 60% of V'O2peak separated by 48 hours of rest: a continuous CE and a combining running, cycling and arm crank for 10 min each. Before (30 min pre) and after (2 hours post) each exercise bout a RMR measurement was carried out in a sitting position (K4b2, Cosmed, Italy). A One-way Anova was used to analyse data and significance was accepted at $p<0,05$.

Results: Oxygen uptake (V'O2) and heart rate (HR) were significantly higher for CE during exercise when compared with CTE (CE: V'O2 1,4±0,2 l/min, HR 138±11 bpm; CTE: V'O2 1,1±0,2 l/min, HR 120±4 bpm; $p<0,05$). No difference was detected during exercise between groups for energy source utilization (CE 116,2±29,7 kcalCHO, 84,8±14,4 kcalFAT; CTE 83,3±25,2 kcalCHO, 75,8±12,5 kcalFAT; ns). O2 consumed during and after CE was higher than CTE (not significantly) even when normalized to the pre-exercise levels (CE: O2tot 71,2±8,1 l; O2net 37,5±11,2 l; CTE: O2tot 65,1±12,1 l; O2net 32,5±7,3 l; ns). On the contrary, EPOC magnitude was higher for CTE than CE, even if not significantly (CE 3,3±2,5 l; CTE 6,1±4,6 l; ns). EPOC accounted for 9,5% and 17% of total energy expenditure for CE and CTE, respectively.

Discussion: These results confirm the ones obtained by Lyons et al. (2006) showing that separating a continuous 30 min exercise into three 10 min exercises will elicit a small but higher EPOC. This could be beneficial for subjects with a low fitness level who are unable to perform one long-bout of exercise on the same ergometer, or to enhance exercise adherence (ACSM, 1998).

CYCLING PEFORMANCE AND CELLFOOD

DJORDJEVIC, S., MILIC, R.

1. UNIVERSITY OF PRIMORSKA, KOPER, 2. UNIVERSITY OF LJUBLJANA, LJUBLJANA

Introduction: Many supplements on the market today claim they can have a positive effect on adaptation/training process and sport performance. One of these is Cellfood (NuScience Corp., Lancaster, California, USA).The aim of our study was to evaluate the effect of Cellfood supplementation on the cycling performance during 5 weeks of training in the preparation period.

Methods: Subjects consisted of 16 highly trained male competition cyclists (1), age 24.9 ± 3.4 yr., body height (179.5 ± 6.2cm) and body mass (70.3 ± 3.5 kg). The primary mode of training was cycling 8 times per week (4 times aerobic, 3 times mixed aerobic + anaerobic and once per week speed-anaerobic type of training load).

Testing Procedures

After 15 min warm-up on their bicycle set up on a cycle ergometer (SpinTrainer - TechnoGymTM) cyclist proceeded with incremental test (initial load 150 watts (W), increase 20 W min-1 to volitional fatigue), (2,3). Heart rate, ventilatory and gas data were collected continuously during the test with Cosmed K4b2 portable device. Lactate samples (20µl) were analyzed on Eppendorf Ebio +.

Measurements and Supplementation Procedure

Cyclist were randomly divided in two groups: the first group (CF group) took 12 drops of CellFood dissolved in 0.15l of purified water, or juice, 3 times per day— once during physical activity. The second group (Control group C) took 7% saline solution and citrus artificial flavoring in original packaging to mimic the acidic taste of Cellfood. Both groups started with the procedure the day after the initial measurement and finish after 5 weeks. The second measurement was one day after the last day of supplementation.

Statistical Analyses

Descriptive statistics included mean, standard deviation and Student's t-Test for matched pairs (p value of < 0.05).

Results: Both groups demonstrated improvement in maximum power and VO2 max. In CF group the improvement was statistically significant (p ≤ 0.01) in maximal power and VO2 max, in the other hand, the control group showed statistically significant improvement (p ≤ 0.01) in VO2 max but not in maximal power. Lactate level and maximal hart rate were not statistically significant changed in both groups after 5 weeks of training

Discussion: Both groups showed similar trends of changes (maximal power, VO2 max, maximal lactate level) but more statistically significant improvements/changes are observed in the CF group (maximal power (p ≤ 0.01), VO2 max (p ≤ 0.01) and lactate level (p ≤ 0.01) compared with the control group (VO2 max (p ≤ 0.05). Based on this preliminary study results we cannot reject hypothesis that Cellfood is beneficial to the adaptation process for the period of 5 weeks training of highly trained (international level) cyclist. The mechanisms of the changes and the effect of Cellfood on adaptation will be the subject of future studies.

THE '4 X 3000M CYCLING FIELD TEST' CAN BE USED TO EVALUATE PERCEIVED EXERTION AND TO DETERMINE TRAINING ZONES FOR CYCLING

MÜLLER, B., STEINER, T., WEHRLIN, J.P.

SWISS FEDERAL INSTITUTE OF SPORTS, SWISS CYCLING FEDERATION, HOUSE OF SPORTS, BERN-ITTIGEN

Introduction: It is important that athletes in elite endurance sport train in specific training zones. Especially young athletes have to learn to correctly estimate the individual training intensities. It is not often possible to test young endurance athletes under laboratory settings and field tests can be an appropriate method to determine individual training zones. However, in most of these tests, the intensities are predetermined and it is difficult to evaluate, if young athletes correctly choose their training intensities. The aims of this study were: firstly, to examine, if Swiss national team cyclists are able to hit the four most common training zones in cycling in a new '4 x 3000m cycling field test' (FTE). Secondly, to investigate how heart rate (HR) at the anaerobic threshold (AT) determined in the FTE corresponds with the HR at AT from laboratory results.

Methods: 21 Swiss national team cyclists from the disciplines mountain bike, road and cycle-cross (15 males and 6 females; age = 15.3 ± 0.5 years) performed at first a progressive test in laboratory (PTL) to determine HR at lactate threshold (LT) as well as at AT (ADAPT-method; Bishop, Jenkins & Mackinnon, 1998). The HR training zones for cyclists were determined as follows: 'easy' < LT, 'medium' between 'easy' and 'hard', 'hard' HR ± 10 bpm at AT and 'all out' > 'hard'. Secondly, the athletes performed the FTE, where they cycled four times 3000m on a 400m track in steady intensities based on their perceived exertion. They tried to hit the training zones 'easy', 'medium', 'hard' and 'all out'. After each 3000m stage, the athletes had a two minute break, when blood lactate was measured. Thereafter, HR at AT in FTE was compared with the HR at AT in PTL (polynomial interpolation of lactate values from PTL at AT for the FTE to determine the corresponding HR).

Results: Nine of 21 athletes hit the four training zones in the FTE correctly. There was no difference in HR at AT (PTL: 178 ± 8 bpm; FTE: 175 ± 9 bpm; p = 0.06). There was no difference (p = 0.59) in HR at AT expressed as percentage of HRmax between PTL (93 ± 2 %) and FTE (92 ± 3 %).

Discussion and Conlusion

Our results showed that less than half of the U17 Swiss national team cyclists were able to hit the four most common training zones. This underlines the importance of training and testing the perceived exertion at this age. HR at AT corresponded highly between both tests, even when the training intensities where not chosen correctly. We suggest that the '4 x 3000m cycling field test' can be a useful tool to evaluate the perceived exertion and to determine the four most common training zones in cycling.

KUWAITI AND HUNGARIAN ELITE MAN HANDBALL PLAYERS

NOÉ, J., RÁNKY, M., MOCSAI, L., PAVLIK, G.

SEMMELWEIS UNIVERSITY AND UNIVERSITY OF PANNONICA

Introduction: International scientists deal with handball players endurance tests and labor tests and matches analysis in Hungary since 2007. We want to reach, the teamsport should be more effective considerating individual differences.The Research Team could check Kuwaiti handball players in the time of their training camp in 2008.

Methods: The Kuwaiti's and Hungarian results comparison, the analysis of the match and a training performance benchmarking according to position the directions of the development of the efficiency.Body combination (with InBody 230), antropometrical indicators, BMI, the examinate of blood pressure, a pulse measurement, oxidative capacity, load tests, stamina runner and handballspecific tests, matches, trainingcontroll with the POLAR Team System.

Results: We experimented considerable, significant differences in the stamina runner tests the lengths (20m/piece) and in the look of the accomplished largest velocities (km/h). Group m1=Hungarian elite players, m2=Hungarian NB/II, k=Kuwaiti group. (Stamina runner test m1= 101, m2=98, k=85,velocities m1=13,8, m2=14, k=13) The best oxidative capacity it in the group m1 we measured, the other two group lagged behind the sport (handball) relative VO2 average (55-60 ml/kg/min), (m1=57,25, m2=51,7, k=50 ml/kg/min). The relative VO2 has significant contact with the bodyweight and the body fat. At the Left and Right Wing and Right Back in the handball players were better, than the other one (m1 W/B Pl.=60,5, m2=61, k=57). The HR maximum and restitution values the average pulse and the blood pressure and a significant contact/context was showed with the height.

Summary: The Hungarian elite handball players provided outstanding performance. For example based on the anaerobic threshold (AT) values the players in the extreme position were faster, but the pivot and shooting players were of stamina. But the Pendulum running test was distignuished by the Center Back players (142 lengths). The direction of the development has to the respect of the individual differences. The OwnZone special training plans into a respiratory period as a standlone program, in other training this period will be 1-2 times week, because the oxidative capacity, the calmness pulse and blood pressure will be right. The time regeneration and his quality is very important between the matches (much more aerob training- running, spinning, swimming- stretching with a suitable type, massage, and relaxing).

ZEN AND THE ART OF SWIMMING – IMPULSES FOR TEACHING AND TRAINING

DAHL, D.

NORWEGIAN UNIVERSITY OF SPORT AND PHYSICAL EDUCATION

Introduction: There is no other physical activity which concerns human beings as existentially as swimming. In a way our existence is connected with movement in water. If you cannot swim, you can loose your life when falling into water. The first movement after conception for all human beings is swimming in one's mother's womb. Regardless of culture, gender, nationality or religion, swimming has been seen as an essential and basic ability of human beings.

Methods: In this paper we shall have a look at a combination of spirituality, physical education and training, in relation to the learning and practice of swimming. For that purpose this study examines the Zen - Buddhist perspective regarding body and movement (cf. DESHIMARU-ROSHI 1984; MOEGLING 1987; SEKIDA 2005). Some elementary concepts from the Zen Buddhist philosophy shall be discussed, in order to reveal and compare constructive elements for and with the "Art of Swimming". By using text analysis and empirical case studies the main aim is to give new impulses for teaching and training swimming activities.

Results/Discussion: At first the combination of Zen and Swimming may seem unusual, but on closer scrutiny Zen Buddhist philosophy and spiritual practice highlights factors supporting the experience of swimming. Notably for tackling problems during the learning process, spiritual experiences from Zen may be complimentary. The paper aims to show some associations and parallels between the concepts of emptiness, wholeness, being vs. non-being as well as meditation techniques of breathing and awareness with important elements of swimming on different levels. Those provide new impulses for teaching and training swimming.

MULTIVARIATE TIME SERIES MODELING OF THE TRAINING-PERFORMANCE RELATIONSHIP WITH ARTIFICIAL NEURAL NETWORKS

HAAR, B., ALT, W.W.

UNIVERSITY OF STUTTGART

Introduction: The knowledge of the highly individualised and complex relationship between training and performance is important to manage athletes' training programs. Modeling the training-performance relationship makes a contribution to optimize training load and regeneration. So far different models have been developed. They either model only a bi-variate relationship between a global training input and the performance output (Banister et. al, 1975; Perl et al., 2001; Brückner and Wilhelm, 2008) or they don't handle the training process as time series (Edelmann-Nusser et al., 2002). Hence no time series model reflects simultaneously the multi-faceted training input that affects performance development. Therefore, the aim of this study was to develop a multivariate times series model to reproduce and predict the individual relationship between training and performance.

Methods: A backpropagation net was used for multivariate time series modeling. The artificial neural net (ANN) consisted of 12 input, 8 hidden neurons and 1 output neuron. Data consisted of a four week endurance training period (Brückner and Wilhelm, 2008). Training loads and ratings of perceived exertion (RPE) were recorded as training input daily. The performance output was also measured daily. All time series were divided into four day sections. Four sequenced values t-1, .., t-4 of all time series were used as net training input and the performance data at the time t as net training output. The ANN should learn to predict the fifth value on the basis of the last four values. Hence 34 training patterns with 12 input and 1 output data were used for the net training. Four subsequent values were predicted.

Results: The original data set was quite well reproduced by the model. Significant correlations were observed between the original data and the modeled performance ($r = 0.86$, $P<0.001$). The prediction of the four subsequent values showed less optimal results. The mean absolute error (MAE) was 0.1 or 10%.

Discussion: Time series modeling of the training-performance relationship upon ANN seems to be a quite powerful method. For the first time it is possible to take the multi-faceted factors that affect performance development into account. The goodness of the model adaptation can be compared to the results by Brückner and Wilhelm (2008). Since this paper documents work in progress even better results for model adaptation and prediction are expected in future.

COGNITION AND PHYSICAL ACTIVITY IN KINDERGARTEN - DEVELOPMENT OF A PHYSICAL ACTIVITY PROGRAM FOR THE IMPROVEMENT OF COGNITIVE ABILITIES AND THE QUESTION OF HOW TO ASSESS COGNITIVE CONTROL

EVERKE, J., GRZYB, K.R., HÜBNER, R., WOLL, A.

UNIVERSITY OF KONSTANZ

Introduction: Physiological processes in the brain, visualized by new technologies (fMRT) since the early 90s, have shown that physical activity has a positive impact on brain function. Scientific studies involving motor and cognitive ability tests came to the same positive conclusion.

Motor activity and cognition:

There appears to be a strong link between coordinative abilities (e.g. balance) and cognitive abilities (e.g. concentration). However, there is a lack of research in controlled evidence based intervention studies relating to transfer effects from motor ability programs to cognitive abilities.

Moreover, the relation between more specific components of motor and cognitive abilities (e.g. selective attention, inhibitory control, behavioral self-monitoring) remains largely unclear.

Methods: The purpose of the first study is the evaluation of the question whether the transfer effects of a physical activity program (e.g. balance) for preschool children lead to the improvement of cognitive abilities (e.g. concentration, memory). In a pre- and post-test experimental design, 75 kindergarten children (3-5 years) participated in a three-month physical activity program, while those in the control groups, divided into an internal (n= 75) and an external (n=20) control group participated in the regular curriculum. The treatment (5times/week) ended after 12 weeks and the follow-up evaluation was conducted after another 12 weeks. Both groups were tested for motor skills and cognitive abilities. The CoMiK-study is a longitudinal and intervention study.

The purpose of an additional second study was the assessment of different measures of cognitive control. Selective attention and behavioral self-monitoring was measured with an Erikson-Flanker task. Inhibitory control was measured with a stop-signal task. In both paradigms, reaction time data is collected. The Erikson Flanker task is a widely used paradigm in which participants have to suppress irrelevant information and focus on relevant information in the environment. In the stop-signal task, a primary response has to be inhibited on some trials whenever a stop-signal appears. The response latency to the stop-signal serves as a measure for the ability to inhibit a prepotent response.

Results and discussion: Results of the first study can support the hypothesis of a positive impact of a physical activity program for preschool children. The experimental group showed improvement compared to the control groups on the concentration task, which were statistically significant for the external control group.

Results from the second study show the usefulness of more specific theoretical constructs for a deeper understanding of the relation between motor and cognitive abilities.

Conclusion: More research in experimental design studies needs to be undertaken to support and substantiate the transfer and causation hypothesis.

EFFECT OF COORDINATIVE EXERCISES ON CHILDREN'S ATTENTION

GALLOTTA, M.C., EMERENZIANI, G.P., GUIDETTI, L., BALDARI, C., BONAVOLONTÀ, V., FRANCIOSI, E.

UNIVERSITY OF ROME

Introduction: The mandatory primary school Italian Physical Education (P.E.) curriculum is structured to promote children physiological, emotional, social and cognitive development. Many studies revealed evidence of the positive effects of P.E. on children psychophysical development (Serbescu et al., 2006), but there is a lack of studies focusing on the contribution of P.E. on their cognitive development and attentional performance (Tomporowski, 2003). Moreover, little is known about the positive effects of coordinative exercise on cognitive functioning during development (Budde et al., 2008). Therefore, the purpose of this study was to assess the effects of two different physical exercise conditions on children cognitive performance. In particular, the study was performed to investigate whether acute coordinative exercises during the school time may have positive effects on concentration and attentional performance in young children.

Methods: Nineteen children aged 9-10 years of a primary school were tested using the d2-test to assess their attention and concentration. Children performed the d2-test before and after a traditional and an experimental P.E. characterized by a high variability of motor coordination and skill learning demands. The total number of items processed (TN) within the d2-test, the percentage of errors (E%), and the concentration performance (CP) were calculated and used as a parameter for sustained attention and concentration. TN value was a quantitative measure of the working speed, E% was a qualitative measure of performance, representing the proportion of errors made within the area of all items processed, and CP was an objective measure of concentration, representing the number of the correct responses minus the errors. Exercise intensity was monitored using Rating of Perceived Exertion Scale (RPE) (Borg, 1982).

Results: The TN and the E% did not significantly change after the two P.E. conditions while the CP significantly improved after the experimental P.E. lesson ($p<0.01$). Finally, RPE revealed that the traditional P.E. lesson was more intense than the experimental lesson ($p<0.05$).

Discussion: The only improvement of CP after the experimental P.E. lesson could be partly explained by the lower intensity of the experimental than the traditional lesson and partly by the coordinative character of the experimental lesson that could induce improvement in concentration performance due to the neuro-physiological adaptations induced by the motor complexity of the coordinative exercises (Budde et al., 2008).

PARENTAL PERCEPTION OF CHILDHOOD OBESITY IN AN INNER-CITY AREA OF PALERMO, ITALY

BIANCO, A., BELLAFIORE, M., BATTAGLIA, G., MAMMINA, C., PALMA, A.

UNIVERSITY OF PALERMO

Introduction: The prevalence of overweight and obesity in Sicilian schoolchildren is one of the highest ever reported: indeed, prevalence of overweight and obesity appears to be nearly 40% at age 11 and over 25% at age 15. Excessive weight during childhood stems from

several interacting factors, including poor diet and exercise habits. The objective of this study was to evaluate in a sample of parents living in an inner-city area of Palermo, Italy, the perception of weight excess as a problem in childhood and the awareness about the role of physical activity, beliefs about contributors and parties having responsibility in counteracting the obesity crisis.

Methods: A cross-sectional survey was performed on a convenience sample of parents of 6-13 year-old children who attended grades 1, 3 and 5 of primary and grades 1 and 3 of secondary public schools, respectively. Thirteen schools were selected in an inner urban district of Palermo, Italy, this district being characterized by having a population of low to medium income residents. Parents were asked to come to the school and participate in the investigation. The survey was administered in the spring of 2006. After a descriptive analysis, role of specific demographic and social characteristics – education, gender, age class and BMI - of respondents was assessed by univariate and multivariate logistic regression analysis.

Results: Three hundred eleven parents completed the questionnaire. Eighty-three percent believed that being obese in childhood is a serious health hazard, but one third still interpreted the child's weight excess as an expression of health. The most significant contributors to childhood obesity were thought to be junk food and beverages (78.0%) and fast food (63.2%), followed by lack of exercise in school curriculum (48.7%). Beliefs about responsibilities for combating childhood obesity significantly varied according to education level. Logistic regression revealed that a lower mother's education level was negatively and significantly associated with perception of junk food and beverages, lack of exercise at school, lack of places to exercise and lack of security as health threats in childhood. Furthermore, mother's low education was negatively associated in a statistically significant manner with attribution of responsibility to fight overweight to food companies, school and healthcare services.

Discussion: Public support for environmental changes could more effectively rise with the increasing public awareness that many interrelated obesogenic factors in the modern environment are playing a key role.

PHYSICAL ACTIVITY AND ACTIVITY TYPE DURING SCHOOL RECESS IN ELEMENTARY SCHOOLS

JANS, L., SLINGERLAND, M., BORGHOUTS, L.

FONTYS UNIVERSITY OF APPLIED SCIENCES

Background: It is recommended for children to engage in at least one hour of moderate to vigorous physical activity (MVPA) every day. Non- intervention school recess can contribute substantially (5-40%) to this guideline (1). Does school recess contribute to motor skill development as well?

The purpose of this study was to investigate the variability in physical activity and activity type during recess on 4 elementary schools in the Netherlands.

Methods: SOFIT (System for Observing Fitness Instruction Time) (2) and SOPLAY (System for Observing Play and Leisure Activity in Youth) (3) were integrated and modified specifically for this study to measure the amount of moderate-to-vigorous physical activity (MVPA) and the activity type. 343 Children (4-12 year) were observed by trained observers during 24 breaks.

Results: Inter-observer reliability physical activity exceeded 71% (average: 76%); activity type exceeded 74% (average 81%). Children engaged in MVPA 22,5% of recess time and in vigorous physical activity (VPA) for 7,1%. 10-12 Year old boys were significantly more active than girls at this age (22,7% vs 15,7%; $p<.05$).

More than one third of the time (38%) children showed no specific activity; 29% was spent walking and running. Other activity types (e.g. climbing, balancing, jumping, ball play) were performed less than 8% of the time each.

Girls spent significantly ($p<.01$) more time tumbling and jumping, boys more time with ball play ($p<.01$).

4-6 Year old children spend significantly ($p<.01$) less time walking/running, jumping and romping games, than older children, but were more active ($p<.01$) on bikes and play-cars (these being unavailable to the older children).

Conclusion: There is relatively little complex (non-ambulatory) activity in Dutch elementary school recess, and MVPA is relatively low; school recess contributes only 5,6% to the desired daily MVPA of children. Both findings could be due to short recess-times, usually 15 minutes morning break for 6-12 year old children. This might be too short to commence more complex activities needing a certain level of organisation. In order to stimulate physical activity and motor development in schools, studies might aim at developing interventions that can be implemented during recess. We speculate that elementary school physical education could play an important role herein.

FUNDAMENTAL MOTOR SKILLS OF PREADOLOSCENTS IN NORTHERN ITALY: A CROSS-SECTIONAL COMPARISON BETWEEN THE 70'S AND THE PRESENT DAYS

CASOLO, F., FRATTINI, G., CEREDA, F., GALVANI, K., MONDONI, M., VAGO, P.

CATHOLIC UNIVERSITY, MILAN

INTRODUCTION : Among the most common gross-motor abilities running, jumping and throwing have been considered some of the most important fundamental motor skills (FMS).Their development, 30 years ago,was guaranteed and performed throught a natural and active life style.Today the scholastic sport activitie and the structured extra scholastic sport activities are not enough to guarantee quantity and quality of motor development of our preadolescents. The study shows how since the late 1970s one can see a progressive motor impoverishment related to the principal gross-motor abilities(1),caused by the diminution of movement opportunities for our children(2)and by the advent of computers,cellular telephones and electronic static games.

METHODS :In the year 1976 a test battery was proposed to 1000 students.The same test battery was proposed to 500 students in 2007.The data have been collected through the scholastic system by submitting tests during PE lessons after a 20 minutes warm-up.Test battery: Speed run (boys mt.80; girls mt.60), Endurance run(mt.1000), Long Jump, High jump, precision throw (Basket drought) and strength throw (one hand throwing of a little ball), twine-skip test and pole-climb test.

RESULTS :After 30 years significant differences have been noticed in the weight, in the height and in the Body Mass Index. Today boys and girls are taller and heavier and we can also notice a marked increase in BMI.All data have been compared with NCHS Growth Charts(3).

In all tests we noticed a loss of ability. These differencies are more evident in endurance and power abilities than in precision tasks. Regarding the gender, these difference are more evident in the girls (increase average of failure 18,59 %) than the in boys (increase average of failure 15,31 %). Differences among the participants according to their ages and birth date were analysed with Pearson's Chi-square test and statistical significance have been confirmed by the O.R.(odds ratio) values.

DISCUSSION:The lack of motor activities in natural environment, the increase of static games, the disappearance of the old courtyard games, the lack of suitable scholastic programs are the causes that, in our opinion, have led to a reduction of FMS. To solve these problems, the following actions seem mandatory: 1)Increase the sporting offer inside the scholastic system;2)Invite P.E. teachers to propose more coordinating exercises based on gross-motor abilities;3)Allocate at least two free afternoons for sporting activities;4)Support a closer interaction and collaboration between scholastic system, out-of-school sportive system and families, in order to enhance a better lifestyle necessary to preserve children health.

PRELIMINARY RESEARCH ON PHYSICAL ABILITIES IN CHILDREN FROM 8-10 YEARS IN GARBAGNATE MILANESE (MI)

MONDONI, M., CASOLO, F., CEREDA, F., COLOMBO, A., PREATONI, E., AJANI, A.

UNIVERSITÀ CATTOLICA SACRO CUORE DI MILANO

Preliminary research on physical abilities in children from 8-10 years in Garbagnate Milanese (MI)

Maurizio Mondoni[1], Francesco Casolo[1], Ferdinando Cereda[1], Alessandro Colombo[1], Ennio Preatoni[1], Anna Ajani[1]

Motor Science, Catholic University of Milan, Italy

This research in 2007-2008 considered 331 children attended the 3th, 4th and the 5th class of Primary School in Garbagnate Milanese (MI) and has been completed with the cooperation of Catholic University of Milan – Motor Science and Sport - graduated students.

The main goal is to know which are the factors that influence overweight and obesity as: the lack of any kind of physical activities, the presence of 'paramorfismi', a poor diet or a wrong feeding.

This work used a questionnaire on the children's habits and style of life, a series of antrophometric and physical test. A medical visit, has been done in each school in order to measure the height, weight, skinfolds, and circumference of the waist..

The trend of the height and weight between these children is nearly equal between males (137, 54 cm ± 6,59; 35,61 kg ± 8,67) and females (136,49 cm ± 7, 06; 35,76 kg ± 7,51). The body mass index it has quite a similar trend between males (18,66 kg/m 2 ± 1) and females (19,11 kg/m 2 ± 1).

The medical visit has underlined that the majority of children does not show accentuations or meaningful reductions of the physiological curves dorsal and lumbar. Booth in females and in males, that there is a slight prevalence of dorsal cifosis level in males and the lumbar lordosis level is greater in females. In overweight children, the presence of knees valgus and varus and of flat feet (around 55%) is frequent specially in males.

In the 40 meters fast run ('shuttle run') males (9,65 s ± 1,02) are faster compared to the females (10,28 s ± 1,04), but not in a significant way ($p<0.002$). In the long standing and forward throw Minibasket ball, the trend is analogous between males (151,50 cm ± 24,75; 4,17 m ± 0,74) and females (129,65 cm ± 24,59; 3,84 cm ± 0,72).

In stick test, males (63,8 cm ± 11,74) obtain better results than females (58,13 cm ± 12,39); in the sit & rich test females (2,83 cm ± 6,84) obtain better results than males (-1,66 cm ± 6,96).

The information from the questionnaire outlined that males (23%) spent more than an hour and half playing, instead females (19%) one hour, come child (4%) told they never play.

About the sport activity practice, males prefer playing soccer, basketball and swimming instead females prefer gymnastic, swimming and volleyball; the 3% of children told they do not play any sport activities.

The few sport activity is associated to a bad way of eating. Only few children (4%) prefer eat meat, cheese and vegetables.

TRACING THE DYNAMICS OF SOME PSYCHOMOTOR PROPERTIES CHANGES, NECESSARY FOR A GOOD PROFESSIONAL REALIZATION OF HIGH GRADUATE ENGINEER SPECIALISTS

ZLATEV, Z.

TECHNICAL UNIVERSITY OF VARNA

The opportunity for a market realization of the young people in a global aspect is one of the most serious problems nowadays. This vitally important problem corresponds directly to the quality of their professional training of different stages of University education and covers : scientific and theoretical knowledge, also development of some psychomotor properties, connected with the profession.

The study of the upcoming changes of dynamics of some psychomotor properties necessary for students professional realization is one of the essential problems of the theory and pedagogical practice in the area of physical culture and sports.

During the analysis through the years some standard psychodiagnostic tests have been implemented in order to define the properties of the attention and evaluation of functional condition of the motive analyzer.

The depth analysis of the results obtained allows some generalization to be reached, which can be expressed as follows :

- Deviations of dynamics changes are established. They are inessential, but in a regressive plan;

- The prognostic matter of the test implemented allows the test to be used at the beginning of the students course of education, so the quality of the preliminary selection of students be improved.

SCHOOL SPORTS PARTICIPATION OUTSIDE IN TOTAL PHYSICAL ACTIVITY OF CHILDREN

SAAR, M., JÜRIMÄE, T.
UNIVERSITY OF TARTU

Low physical activity by children is a risk factor for several chronic diseases. Active children perceive themselves as healthier and fitter than sedentary ones. The aim was to investigate the influence of sports participation on perceived and actual physical fitness, and total physical activity in youth.

METHODS: Participants were 525 10-17-yr-old boys and girls.Children's Physical Activity Index (PAI) was calculated (Telama et al., 1996). Self-perceived endurance, strength, flexibility and body composition were measured by Lamb and Haworth (1998). Questions about the satisfaction of physical activity, participation in organized physical activity and in competitions and watching competitions were taken from the questionnaire of Telama, et al. (1996). Several EUROFIT (1988) tests were used and sum of skinfolds measured.

RESULTS: Correlations between participation in organized sports and PAI in all age and sex groups ranged from r = 0.30 to 0.61. From the perceived motor abilities, the endurance correlated with the satisfaction of exercising (r = 0.28 – 0.49). Endurance shuttle-run test results correlated with satisfaction with exercise (r = 0.29 –0.50). Participation in organized physical activity was correlated significantly with perceived endurance (r = 0.37 – 0.44) and strength (r =0.29 – 0.70). However, actual results of endurance shuttle-run test correlated with participation in organized physical activity only in 12-13 and 14-15-yr old groups (r = 0.32 – 0.61). Participation in competitions in the youngest age group correlated with perceived endurance (r =0.30), strength (r =0.48) and flexibility (r =0.28) in boys. Actual results in endurance shuttle-run test correlated with the participation in competition in every age and sex group (r = 0.30 – 0.44). Watching competitions was not correlated with perceived or actual motor abilities except perceived endurance (r = 0.28), strength (r = 0.48) and flexibility (r = 0.27) in 16-17-yr-old girls.

DISCUSSION: Sports participation, especially in girls, decreased between the ages of 13 and 18. Self-perceived endurance and strength correlated with satisfaction of exercising.

The relationship between health-related physical fitness and physical activity in children was significant but moderate.

CONTRIBUTION OF PHYSICAL EDUCATION LESSONS TO PHYSICAL ACTIVITY LEVELS OF DUTCH PRIMARY AND SECONDARY SCHOOL STUDENTS

SLINGERLAND, M., BORGHOUTS, L.
FONTYS UNIVERSITY OF APPLIED SCIENCES

Introduction:

Dutch youngsters' overweight and obesity rates are alarming and physical activity (PA) guideline compliance is low, especially in urban areas and ethnic minorities.1 Physical education (PE) could make a meaningful contribution to the daily accumulation of physical activity needed for health benefits. However, to date, the contribution of PE to the daily accumulation of PA in Dutch youngsters is unknown.

Objective: To establish the contribution of primary and secondary school PE to the accumulation of daily moderate-to-vigorous physical activity (MVPA), as recommended in recent PA guidelines for children and adolescents.2

Methods: Data was collected from August 2008 until February 2009 in 12 primary schools and 12 secondary schools, distributed equally over the country. Heart rate data of 261 primary school children (age range 8-13) and 383 secondary school children (age range 14-18) was collected during PE-lessons. Primary school lessons were either taught by a specialized PE-teacher or by the classroom teacher. Secondary school PE-lessons were solely taught by specialized PE-teachers.

Results: Percentage MVPA during PE was 50% ± 19% vs. 38% ± 23% or 19 ± 10 vs. 21 ± 14 min per lesson (primary vs. secondary school; p<.000). No difference was observed between primary school boys and girls or between lessons taught by specialized PE or classroom teachers. In secondary schools however, boys were more active during PE than girls (32% and 45% of MVPA respectively p<.003). Assuming an average of 2 PE-lessons per week, contribution of PE to the total weekly amount of PA needed for health benefits was 9% and 10% respectively for primary and secondary school students.

Discussion and Conclusion: In the U.S., Healthy People 20103 stated that MVPA during PE should be 50%. There are no similar guidelines in the Netherlands. Time spent in MVPA during primary school PE-lessons in the Netherlands is exactly conform the U.S. Healthy People 20103 objective, while secondary school PE was well below this level. Intervention strategies to increase PE-time spent in MVPA should therefore primarily be focused on secondary school students and on secondary school girls in particular. However, increasing the frequency and duration of PE-lessons might be a more effective strategy to increase children's' and adolescents' daily PA through PE-lessons.

4TH GRADERS' SOCIAL STANDING WITH PEERS – A PROSPECTIVE STUDY ON THE ROLE OF 1ST GRADE PHYSICAL ACTIVITY, WEIGHT STATUS AND MOTOR PROFICIENCY

OMMUNDSEN, Y., AASEN GUNDERSEN, K., MJAAVATN, P.E.

NORWEGIAN SCHOOL OF SPORT SCIENCES; UNIVERSITY OF AGDER, NORWAY; NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, NORWAY

Introduction: Young peoples' physical - motor function and status when entering primary school may impact on their later psychosocial development (Cummings et al., 2005). In order to identify targets for interventions to promote a healthy psychosocial functioning and development during school years, the relative role of various influencing factors seem important to identify. In the present study we examined the role of 1st grade pupils' physical activity involvement, weight status, and motor functioning capability for their social status among class peers four school years later, in 4th grade.

Methods: The total number of children originally sampled consists of 118 Norwegian 1st grade children (Girls N= 64; Boys, N= 54) representing 3 different schools. These children were followed from grade 1 (6 year old) to grade 4 (9 year old) in a study with the overall purpose to examine determinants of children's physical activity, and to study possible consequences of children's physical and motor status, functioning and development for their psychological and social development. The 80 children Girls N= 44; Boys, N= 36) that provided data at both grade 1 and grade 4 make the sample for the present study. Measures included records of objectively measured physical activity, weight status (BMI), test of motor proficiency (KTK) and a peer nomination procedure to obtain sociometric status among peers.

Results: When controlling for sociometric status at time 1 (beta = .20, p<.001) in a first step (R2change=0.04), objectively reported physical activity (CSA) in grade 1 (beta = .22, p<.001) and motor ability (KTK) in grade 1 (beta = .20, p<.001), were both genuine and positive predictors of sociometric status in 4th grade (R2change=0.09). In contrast, neither 1st grade Body mass index (BMI) (beta = -.05, p>.05) nor gender (beta = -.04, p>.05) did predict sociometric status four school years later (grade four). Interaction findings also revealed that 1st grade healthy weight children benefit more in terms of their social standing among peers in 4th grade by also being proficient in the motor domain than do 1st grade overweight children. A gender moderation effect was also seen in that being physically active seems of greater importance for these 1st grade girls' 4th grade social standing among peers than is the case for the 1st grade boys.

Discussion: Findings point to the role of motor functioning and physical activity for young peoples' social standing among peers in school. Results may inform early intervention efforts in school to enhance a healthy psychosocial development among school children in the primary school years.

BODY AND HEALTH: THE CALORIC EFFECTS OF A DIDACTIC FOCUSED ON THE BODY AND MOVEMENT FOR THE ACCESS TO KNOWLEDGE

D ELIA, F., GALDIERI, M., BALDASSARRE, G., AIELLO, P., SIBILIO, M.

UNIVERSITY OF SALERNO

Introduction: The lack of methodological and didactic knowledge, that would allow the teacher to offer educational activities suitable to the different needs of students, makes the enhancement of body-centered teaching methods essential. These methods are related to various psycho-educational and philosophical, neuropsychological, neurophysiological and neurobiological models that give value to the didactic-educational potential of the movement.

Objective: The objective of this work was to identify significant differences in the use of traditional teaching methods and body-centered didactics, through the measurement of energy expenditure during school activities in order to implement the use of motor activities in the school.

Material and Methods: The study has been carried out within an action-research in 14 schools affiliated with the Department of Educational Sciences of the University of Salerno.

The experimental protocol was previously established through a joint action between the school teachers and researchers, who shared the methodology to be used during the action- research.

The difference in energy expenditure during traditional teaching/learning activities and activities centered on the body and movement was measured quantitatively through the use of calorimeters.

The study was carried out on a sample of 95 children (45F-50M) aged between 7 and 10 years and 12 to 15 years, attending primary school and low secondary school in the province of Salerno (Italy).

This sample was divided into two groups:

1) the control group, which lived an experience of traditional teaching/learning activity (frontal lesson);

2) the experimental group which performed bodily/motor activities using a teaching method aimed to transfer knowledge from other disciplines (in particular the historical and spatial area) through body and movement .

Physiological variables and data of physical activity were sampled during the school activities through the use of multi-sensor monitor Sense Wear Armband, put on the right triceps of the students during the school activities.

Results: Data related to the energy expenditure, levels of activity and other parameters has allowed to analyze a relationship between the considered variables and the teaching methodology used.

POSSIBLE INTERPRETIVE KEYS ON THE RELATIONSHIP BETWEEN THE PHENOMENOLOGICAL AND BEHAVIOURIST THEORIES ON THE DIDACTICS OF MOVEMENT AND RESULTS OF NEUROSCIENTIFIC RESEARCH ON MIRROR NEURONS

RAIOLA, G., PALUMBO, C., FULGIONE, M., NICOLOSI, S., SIBILIO, M.

1. UNIVERSITY OF CASSINO, 2. UNIVERSITY OF SALERNO, 3.UNIVERSITY

Introduction: Recent findings about some specific neurons have demonstrated the ability of certain cells of the brain to fire when they see, hear, feel or imagine a movement as well as demonstrated by the use of instruments for neuro-imaging. The functionality of these structures offers new perspectives on the teaching and specifically on 'teaching methods and didactics of motor activities" questioning the theories on motor control.

In this perspective, action, perception and knowledge are a single process and can no longer be considered separately:

1. perception,
2. processing
3. planning
4.execution

Objective

Defining possible interpretations keys on the relationship between the phenomenological and behaviourist theories on the teaching of the movement and results of neuroscientific research on mirror neurons

Methods: The present research is a theoretical and argumentative one:

• On models and methods of teaching activities according to the main lines of psycho-pedagogic research based on behaviourism and phenomenology;

• On the relationship between the results of research on mirror neurons and the teaching of movement

Results: The method of motor activities teaching to improve performance has long been the demonstration of gesture and technical action and the education action has been the mirror of this approach in Italy. The fundamentals of this theoretical model are to be found in behaviourism which was based on external sensory stimulation mechanism and the predetermined response, induced and required at all.

The phenomenology, a philosophical approach, focused the attention on the function of the interaction body-environment and person-subject in the mechanisms of learning, knowing and anticipating the knowledge of the real functioning of perceptual phenomena (mirror neurons). The discovery of mirror neurons found evidence and consistent interpretative keys in his phenomenology of perception (Iacoboni, Welsh 2008) that binds together perception and knowledge in a continuous process , offering new perspectives on different teaching methods and activities motor.

Discussion: The results show a substantial relationship between the recent neuroscientific findings on mirror neurons and the phenomenological and behaviourist theoretical system.

PRIMUS-STUDY - PSYCHOSOCIAL RESOURCES IN YOUTH SPORT: CONCEPT, IMPLEMENTATION AND EVALUATION

SYGUSCH, R., HERRMANN, CH.

UNIVERSITY OF MAINZ

Introduction: Organized youth sport is often associated with capabilities for individual development. On the one hand it is assumed that sports contribute to the promotion of psychosocial re-sources (e.g. social support, self-efficacy). On the other hand, we know that psychosocial resources contribute to the development of capacity for action and performance in sports.

The conceptual framework „Psychosocial Resources in youth sport" (Sygusch, 2007) is an approach for the promotion of self-concept, self-efficacy, social competence and group cohesion. This approach orientates on the requirements of daily routine of training and competition in different sports. For the promotion of the resources, the concept formulates targets and develops methods for realization in training. Meanwhile there exist transfer concepts for gymnastics and handball.

To evaluate these transfer concepts they have been realized in 33 training groups (age 12-16 years) over seven months. In the current research of evaluation it is recommended to examine the effectiveness of the program in relation to the realization of the program (exposure and adherence) (Dane and Schneider, 1998; Mittag and Hager, 2000).

Methods: For the evaluation of program realization, exposure and adherence of implementation (de-gree of realization) have been examined via interviews with the coaches (n= 35). For the evaluation of program effectiveness, a controlled trial (n= 400) with three data collections has been carried out. Changes of self-concept, self-efficacy, social competence and group cohesion have been recorded via questionnaires.

Results: The results for the evaluation of program realization show that most coaches arranged the recommended methods in the sense of the concept (adherence) and used them frequently or occasionally (exposure). This percentage of coaches, loyal to the concept, even in-creases from 77% during the first phase of realization to 92% at the end of the interven-tion. The existing data for the evaluation of the program effectiveness are analyzed at the moment and will be presented at the congress.

Discussion: The results of the evaluation of program realization indicate that the transfer concepts are realizable in the daily routine of training and competition in gymnastics and handball. These results are the basis for an improvement of self-concept, self-efficacy, social com-petence and group cohesion in the analyzed training groups. The evaluation of program effectiveness examines the development of psychosocial resources depending on the de-gree of realization as it is recommended in the current research of evaluation (Dane and Schneider, 1998).

SEDENTARY BEHAVIOURS IN RELATION TO BODY-MASS-INDEX DEFINED EXCESS OF WEIGHT IN TEENAGERS LIVING IN A SMALL URBAN CENTRE OF SICILY, ITALY

BIANCO, A., BELLAFIORE, M., BATTAGLIA, G., CARAMAZZA, G., PALMA, A., MAMMINA, C.
UNIVERSITY OF PALERMO, PALERMO OLYMPIC COMMITTEE (CONI)

Introduction: Epidemiological studies indicate that sedentary behaviours are associated with obesity independently of physical activity. The aim of this study was to investigate the association of sedentary behaviours with excess of weight in a sample of children living in a smallest Sicilian town where several confounding factors could be presumed to play a limited role because of a very homogeneous daily lifestyle.
Methods: The investigation involved a randomly selected sample of 100 pupils attending the first grade of secondary education school of a smallest town with 5,485 inhabitants. Sedentary behaviour was assessed by administering a questionnaire including questions about time spent on television and other screen-based entertainment in the week during school and vacation periods. Time spent in daily activities, such as sleeping and meals, and physical activity was also evaluated. Height and weight were measured by the interviewer, BMI was calculated and then categorized in two strata of over- and normal weight. Cross tabulation with chi-square statistics and a one-way analysis of variance (ANOVA) were used to evaluate the relationship between behaviours and BMI. Differences were considered significant at P ≤ 0.05.
Results: The participants were between 11 and 16 years old (median age 13). Forty-three were female. Overall, 68 had a normal weight, whereas 20 were overweight and 12 obese. Normal and overweight subjects did not significantly differ by sleeping hours and time spent having meals, though those overweight were likely to spend less time at lunch and dinner than normal weight pupils (15 minutes or less vs. 30 or more). Similarly, the two BMI groups did not significantly differ by the average weekly hours they spent in physical activity during both school and vacation periods. Time spent in watching TV was also not significantly different during both periods. A strong positive relationship was observed only between BMI and other screen-based entertainment times (videogames, internet) during school period (normal vs overweight, weekly hours mean 3,64, SD 3.66 vs 6.12, SD 5,12, P = 0.01). Remarkable, but not significant, differences were detected between the same behaviours during the vacation period (normal vs overweight, weekly hours mean 6.15, SD 6.05 vs 9.64, SD 9.43, P = 0.08).
Discussion: As a cross-sectional survey, the issue of causality direction remains unsolved and overweight could cause increased time spent in screen-based entertainment activities. However, it is interesting to observe that sedentary behaviours alone appear to be associated to differences in BMI within children and adolescent who were likely sharing most activities at school, such as mandatory physical education or artistic activities, but likely out school also, because of the secluded social setting. More effective public health recommendations should include limiting sedentary behaviours, not only promote physical activity.

THE HELP PROGRAMME: A HEALTH INTERVENTION FOR EMIRATI ADOLESCENTS

SCULLION, L.J., LONEY, T., CARTER, J.M., RAYSON, M.P.
OPTIMAL PERFORMANCE LIMITED

Research has shown that 30% of children in the United Arab Emirates (UAE) are overweight; while the incidence of adolescent (aged 14-17 yr) obesity could be as high as 13% (Malik and Bakir, 2007). This prevalence has contributed to the UAE having the second highest global incidence of diabetes with 29% of the population affected (Saadi et al., 2007).
As lifestyle behaviours are established early in life, intervention strategies to combat the early onset of obesity should be considered. The aim of this study was to pilot a health intervention programme (HELP: Health Education; Lifestyle; Physical activity) on male Emirati adolescents during a residential school camp in the United Kingdom.
Eighty males (Mean ± SD: age 15.5 ± 0.9 yr; BMI 23.0 ± 4.8 kg/m2) participated in the four week study; control group (N = 46; age 15.5 ± 0.9 yr; BMI 22.1 ± 4.6 kg/m2) and HELP group (N = 34; age 15.6 ± 1.0 yr; BMI 24.2 ± 5.0 kg/m2). All subjects completed a Health and Fitness Questionnaire consisting of two sections: International Physical Activity Questionnaire; Lifestyle and Health Knowledge. The HELP group participated in eight 60 minute educational workshops and received a health booklet before the final questionnaire. Educational posters were also displayed in the HELP group's accommodation.
In total, 20% of subjects were overweight, 19% obese and 1% underweight, with no difference between groups. The HELP group experienced significant changes in physical activity (PA) compared to the control group, with increased time spent in vigorous-intensity PA (155 ± 267 min/wk vs. 4 ± 135 min/wk; P < .01) and decreased time spent sitting (-152 ± 216 min/wk vs. 134 ± 303 min/wk; P < .001). Although not significantly different, the HELP group reported an increase in self-reported time spent in moderate-intensity PA compared to the control group (126 ± 481 min/wk vs. -15 ± 210 min/wk; P = .117). The HELP group exhibited an increase in health knowledge (6.8 ± 18.4%; P = .038), while no improvement was reported in the control group (3.1 ± 6.8 %; P = .101). In addition, the HELP group experienced a significant increase in self-reported daily water consumption (490 ± 731 ml; P < .001) and a non-significant increase in self-reported nightly sleep (0.4 ± 1.4 h; P = .160). No change in either variable was reported in the control group.
Improvements in physical activity, lifestyle and health knowledge highlight the benefits of the HELP programme and warrant its inclusion in the daily school routine of students at risk of health complications. Further work to investigate the longitudinal influence of the HELP programme on obesity, and associated diseases, is required.

THE MRI DETERMINATION OF THIGH SUBCUTANEOUS FAT

VORONOV, A.V., LEMESHEVA, J.S.
INSITUTE FOR BIOMEDICAL PROBLEMS

The MRI determination of thigh subcutaneous fat
State research Center of Russian Federation Institute for biomedical Problems RSA

Introduction. Magnetic resonance imaging (MRI) gives the most accurate results of human body tissue measurements. Advantages of this method are distinguishing boundaries between different tissues. The objective of this study was to measure the volume of subcutaneous fat of thigh.

Methods. 87 male subjects of different physical conditions from the ages of 18-45 years were tested for 23 anthropometric characteristics and MRI of right thigh. The subjects were placed so that the MRI imager covered his anatomical formations well determined during palpation. The first cross-section was made in the lower part body across the anterior iliac spines. The last section coincides with the medial knee joint cleft. The total number of sections in the thigh was 20-25, with thickness equal 10 mm. To identify the location of the axial sections a longitudinal section of tested area was made to scale in each segment. The volume of subcutaneous fat was determined by multiplying the areas of adjacent segments section by the distance between the sections.

Results. The average body length was 176,8 6,5 cm, body weight 74,0 9,4 kg. Proximal thigh circumference – 55,6 4,1 cm. The thickness of the middle skin fold on ventral thigh surface – 12,5 5,3 mm. The coefficients of variations (V) for different anthropometrical parameters, except body weight, were less then 8%. Fat subcutaneous volume reached the value 2205 882 cm (V=40%, with maximum value 4218 and minimum value 945 cm). Linear regression equation was calculated to determine the fat volume of the thigh using some anthropometric measurements. The correlation coefficient between the measured and calculated data was r=0,97, with error 198 cm .

INFORMATIVE AND HEALTH-IMPROVING TECHNOLOGIES IN HIGH SCHOOL PHYSICAL EDUCATION OF MEDICALLY FRAGILE STUDENTS

KOVALENKO, T., ULYANOV, D., SHKLYARENKO, A.

VOLGOGRAD STATE UNIVERSITY

Research actual continuity. One of the most upcoming trends of physical education in high school at the present moment is the development of scientific principles for students' health monitoring as well as for their motor education based on actual information technologies.

Academic process methods and management for medically fragile students have their particularities depending on the disease present. Therefore, there is necessity to develop new trends and improve the academic process and programs, elaborate and introduce innovative approaches and technologies.

Research tasks.

1. Development of quantitative model to estimate the medically fragile students health rate.

2. Use of computer-assisted automatic diagnosis equipment (ADE) to appreciate medically fragile students' performance, progress and health rate.

Research methods. The following research methods were applied:

1. Theoretical study and generalizations of existing scientific sources, of progressive and advanced practical experience,

2. Combination of psychologist and pedagogical techniques,

3. Examination of functional body status dynamics Polyvalent estimation of functional body status and health rate of medically fragile students is possible only if based on theoretic and systemic approaches and methods. The modeling systemic approach allowed to represent human health as complex four-level system.

We used a specially designed computer-assisted automatic diagnosis equipment (ADE) to appreciate medically fragile students' performance, progress and health rate. The ADE helped to examine 120 students on their prior diseases among them 80 students in addition were examined on associated diseases using 2 or 3 secondary diagnostic procedures.

Considerable amount of academic and statistics information processing was affected and implemented in academic process of data management. The rising intellectual and psycho-emotional load on major subject, inefficient and low students motor activity bring to progressive health deterioration. At the present moment it is necessary to use express diagnostic methods of observation (monitoring) students health rate based on actual information technologies.

Research conclusions.

1. The additive (summary) model of health rate monitoring was developed. This helped to introduce the rating system to appreciate medically fragile students' performance, progress, health level as well as their physical development grade. The rating system of health status was implemented consequently in the academic process.

2. The development of computer-assisted automatic diagnosis equipment (ADE) to appreciate medically fragile students' health functional status using electrophysiological indicators.

TRADITIONAL NORDIC OUTDOOR LIFE IN RELATION TO WEIGHT STATUS

WESTERSJO, J., BERE, E.

UNIVERSITY OF AGDER

Introduction: A special feature with the Nordic countries is the public rights and access to the countryside, which indeed promotes outdoor recreational life. Most traditional outdoor activities involve some kind of physical activity. Some also involve nutrition, e.g. food gathering, fishing and hunting. Berries, fish and game are among the most nutritious foods there is (Bere & Brug, 09). Therefore, traditional Nordic outdoor life has a great health promoting potential. The purpose of this study is to assess the relationships between four traditional Nordic outdoor activities and weight status, and also to assess potential moderators (sex and SES) of these relationships.

Methods: A questionnaire survey (Sept 08) was conducted among 6th and 7th graders and one of their parents in 27 random schools in two Norwegian counties (Hedmark and Telemark) as part of the FVMM project. A total of 1016 parents participated in the survey (78% women). Family trips in nature (dichotomised into: ≥once a week vs. not), gathering of berries/mushrooms, fishing and hunting (all three dichotomized into: ≥sometimes vs. not), weight, height, sex and family education level (dichotomized into: one or both parents had higher education vs. none) were all reported in the parent questionnaire.

Results: Those engaging in family nature trips (32% overweight) and gathering of berries/mushrooms (39% overweight) were LESS frequently overweight than those respectively not engaging in family nature trips (44% overweight) and not gathering (45% overweight). Those engaging in fishing were MORE frequently overweight than those not fishing, respectively 48% and 37% were overweight. Adjusting for all outdoor activities; those engaging in nature trips (OR=0.54; 95%CI=0.38-0.76) and those engaging in gathering (OR=0.74; 95%CI=0.56-0.99) were still less frequently overweight, while those fishing (OR=1.81; 95%CI=1.35-2.44) were still more frequently overweight. After also adjusting for sex and SES, nature trips (OR=0.49; 95%CI=0.34-0.71) and fishing (OR=1.58; 95%CI=1.16-2.17) were still significant, gathering was not.

Discussion: Bringing your family on frequent trips to nature was associated with a 50% reduction in risk of being overweight, also after adjusting for sex and SES. Gathering of berries/mushrooms was also related to being less frequently overweight. However, this association was affected by sex and SES (women and those in families with higher education are both leaner and engage more often in gathering of berries/mushrooms). Fishing was clearly associated to increased frequency of being overweight, also after adjusting for sex and SES. Hunting was not associated to weight status.

THE EFFECT OF LATERALITY ON YOUNG ATHLETS IN FLAT WATER CANOEING

KRUEGER, T.

UNIVERSITY OF POTSDAM

Introduction: Laterality, the dominance of one hemisphere, and the effect of these two phenomena on sports performance capacity have yet to be described in detail.

Methods: 275 kayakers and canoeists were examined twice annually using extensive kinetic and biomechanical equipment. The athletes were members of a state-wide canoeing club (national junior elite athletes). The main focus of the study was the correlation between (a) force differences arising between the left and right upper extremity and (b) athletic performance under laboratory conditions and field conditions (flat water). The following data was gathered: selected strength capacities (maximum force [FMax]) of the upper arm flexor at a static strength measurement system, force curves at the measuring paddle during exercise tests using the canoe counter current system and canoeing times in flat water over 250 m and 2,000 m during the course of the year.

Results: The results of the static maximum force test showed that the difference in maximum force between the left and right arm increases with age. As maximum force increases, the difference in the mean value of maximum force seems to increase as well. The longitudinal study included only right-handed athletes. In the longitudinal group the assumption seems to be confirmed that right-handers also have greater force in their preferred extremity. Further longitudinal analyses showed that the higher maximum force achievement changes from the right into the left arm with some test subjects.

Discussion: These results show that it is not always possible to determine which side has greater maximum force solely on the basis of handedness. According to Vagenas & Hoshizaki (1988) bilateral differences, which are frequently observed during symmetrical physical activities, may be attributable to the systematic combination of structural and neuromuscular factors. However, there is ongoing controversy about the relationship between preferred extremity (preference dominance) and the extent of force development (achievement dominance). The preferred extremity is commonly believed to possess the higher maximum force level.

Therefore it could be concluded that the morphological organization of the human locomotor system forms the very basis for locomotor movement symmetries. However, due to diverse factors such as differences in extremity lengths and the attendant force levels, movement asymmetries may arise during cyclic movements such as walking and running. This observation is consistent with Starosta's (2002) theory, which holds that ontogenetically induced upper extremity growth differences lead to different leverage lengths and attendant levels of force. Apart from that, the dominant extremity might be used instinctively for movement guidance e.g. during strength training.

EFFECTS OF FUNCTIONAL FATIGUE ON JOINT POSITION SENSE IN MALE ELITE HANDBALL PLAYERS

NIEDERSEER, D., MÖRTL, H., LIEBENSTEINER, M.C., EGGER, A., THALER, C., NIEBAUER, J., RASCHNER, C.

PARACELSUS MEDICAL UNIVERSITY SALZBURG

Background: Worsening of joint position sense due to fatigue results in a worsening of performance in strength and flexibility, and furthermore coincides with an increased risk of trauma. In the present study we investigate the effect of a standardized handball specific fatigue protocol on joint position sense in male elite handball players to localize joints at risk for injury. Material and Methods: Eighteen (9 under-21 players/9 professional players) male handball players (age: 22.3±4.9 years; weight: 85.1±11.3 kg; height: 185.4±5.2 cm) participated in this trial. After a standardized warm up session the athletes participated in a fatigue protocol lasting 45 minutes and 27 seconds. It consisted of 81 accelerations, 9 throws, 18 jumps, 180 ball contacts, 234 changes in direction, 225 changes in speed and a total distance of 4680 m. Of this total distance 7.7 % (360 m) were run faster than 5.2 m/s, 26.9 % (1260 m) between 5.2 and 3.1 m/s, 30.8% (1440 m) between 3 and 1.5 m/s and 34.6 % (1620 m) slower than 1.4 m/s according to present literature on characteristics of professional handball matches. The joint angle as a measure of joint position sense was measured before and after the above protocol in the right and left hips, knees and shoulders by a gravity inclinometer (Plurimeter). The blindfolded athletes had to reproduce a random angle in a standardized position within the range of motion of the investigated joint. The difference between the angle shown and the one reproduced was calculated. Error scores were defined as the sum of two measurements for each joint. Results: The fatigue protocol was performed at an average heart rate of 145±16 bpm. The assessment of joint position sense showed a worsening in 8/18 (44 %), 11/18 (61 %) and 10/18 (56 %) of the athletes' hips, knees and shoulders, respectively. The sum of the error scores of all six investigated joints remained unchanged in 10/18 (56 %) athletes, worsened in 7/18 (39 %), and only improved in 1/18 (6 %). The mean change worsened from 29.2°±13.3° at pre-test to 40.8°±17.0° at post-test (p=0.03), i.e. +11.6°±19.2° or 37 %. On average athletes were able to reproduce angles with an error of 3°±6° (p=0.09), 2°±13° (p=0.52) and 7°±12°(p=0.02) in hips, knees and shoulders, respectively. No difference was ob-

served comparing the dominant versus the non-dominant shoulder or under-21 athletes versus professional players. Conclusion: Joint position sense abilities worsened in the shoulders, whereas measurements for hips and knees remained essentially unchanged. Joint position sense of the shoulder, but not the hip or knee can be altered with a handball specific fatigue protocol. Sensomotoric training as well as prevention and rehabilitation of joint injuries might help to correct this important factor in handball.

THE EFFECT OF TARGETED ENDURANCE/STRENGTH TRAINING ON SELECTED PARAMETERS OF LIPOMETABOLISM OF NON INSULIN DEPENDENT DIABETICS

PILLMANN, N., KREUTZ, T., HOFRICHTER, A., SCHMITZ, A., BRIXIUS, K., BLOCH, W., GRAF, C.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: Type 2 diabetes is increasingly among the overweight and obese. An essential therapeutic approach to treating the disease involves endurance training. The benefit of strength training is inconsistently discussed. Therefore, the aim of this study was to examine the effects of three month endurance/strength training regime on the anthropometric data and on selected laboratory parameters (Leptin, Adiponektin, Resistin), of 46 male non insulin diabetics.

Methods: The initial (T1) and final (T2) examination of anthropometric and laboratory data was assessed after a 12 hour period of fasting. 31 subjects (58,6±9,2 yr., 1,79±0,10 m, 108,5±14,0 kg, 33,7±4,3 kg/m²) completed endurance training (ET), while 15 subjects (61,7±9,0 yr, 1,79±0,1 m, 89,1±11,7kg, 27,9±3,5) completed strength training (ST). The two groups differed with regard to weight and BMI (p≤0,001 respectively). The training took place twice a week for a period of 60 minutes.

Results: Following the intervention, a reduction of BMI (0,34±0,59 kg/m² (p=0,005)) was documented in the ET and an increase of watt performance (13,3±22,9 Watt (p=0,041)) was documented in the ST. With respect to the laboratory parameters, a decrease in the Resistin level (47,0±66,7 pg/ml in the endurance group and 27,7±29,3 pg/ml in the strength group (p<0,05 respectively)) was observed in the endurance group and strength group respectively. The remaining parameters revealed no significant change. No significant difference between the endurance group and the strength group, adjusted for age, BMI, and results of the entry examination, was observed.

Conclusion: A 3 month exercise program, independent of the type of exercise program among type 2 diabetics, leads not only to a decrease in the BMI and increase in physical strength, but also to an improvement of the Resistin level. Further studies with higher frequency and/or intensity of exercise are needed, to elucidate the effects.

UNSUPERVISED HOME-BASED PROPRIOCEPTIVE TRAINING REDUCES THE INCIDENCE OF ANKLE SPRAIN RECURRENCES: REPORT OF A RCT.

HUPPERETS, M.

EMGO INSTITUTE/VU UNIVERSITY MEDICAL CENTER

Objectives: To evaluate the effectiveness on ankle sprain recurrences of an unsupervised proprioceptive training programme, that was applied after the usual care of individual athletes who had sustained an acute sports-related lateral ankle ligament injury.

Methods: 522 male and female athletes, who recently had sustained a lateral ankle sprain, were followed prospectively for one year. Athletes were randomized after usual care treatment to an intervention group (256 athletes) or a control group (266 athletes). Intervention athletes followed a prescribed proprioceptive training programme; control athletes only underwent usual care. A sub-group analysis was performed between medical treatment and self-treatment. Outcomes were assessed at baseline and every month for 12 months. Analyses were performed according to intention to treat.

Results: Significantly less recurrent ankle sprains were found in the intervention group compared to the control group. This effect was found for subjectively reported recurrent ankle sprains (RR=0.63; 95% CI: 0.45 – 0.88), for recurrent ankle sprains leading to loss of sports participation (RR=0.53; 95% CI: 0.32 – 0.88), as well as for recurrent ankle sprains resulting in costs through direct health care costs or indirect costs due to absenteeism from work (RR=0.25; 95% CI: 0.12 – 0.50). No significant differences were found between self-treated intervention group athletes and medically treated controls. This was shown for self reported recurrences (RR=0.71; 95% CI: 0.43 – 1.18) and for recurrences leading to sports absence (RR=0.54; 95% CI: 0.26 – 1.14). A lower recurrence risk leading to costs was found for the self-treated intervention group compared to the medically treated control group (RR=0.32; 95% CI: 0.13 – 0.81).

Conclusions: The use of a proprioceptive training programme after usual care of an ankle sprain is effective for the prevention of ankle sprain recurrences. A proprioceptive training after self-treatment of the initial ankle sprain is equally effective as post-injury medical treatment only.

COMPRESSIVE SLEEVE IMPROVES THE PASSIVE ELBOW POSITIONING SENSE

THEDON, T., FOISSAC, M., MOTTET, D., PERREY, S.

EA 2991 MOTOR EFFICIENCY AND DEFICIENCY LABORATORY, FACULTY OF SPORT SCIENCES, 700 AVENUE DU PIC SAINT LOUP 34090 MONTPELLIER ; OXYLANE RESEARCH, 4 BOULEVARD DE MONS 59650 VILLENEUVE D'ASCQ, FRANCE.

Several studies demonstrated an improvement of joint position sense with a brace, and this effect is attributed to the stimulation of cutaneous mechanoreceptors (Khabie et al., 1998). However, it is unknown if this effect is proportional to the pressure or not. The objective of our study was to examine the effects of different compressive pressures on elbow joint positioning sense.

Twelve healthy participants (age 27.2 ± 3.5 yr) volunteered to this study. Their dominant forearm was passively moved from the start position angle (-45° to the horizontal plane) towards one of the three different target angles (- 25°, 0°, 40° to the horizontal plane). Subjects were told to stop the moving arm, using the hand held disengage switch, when they detected the prepositioned angle. Each target was repeated while wearing sleeves with different pressures (0, 10, 15 and 20 mmHg) in a randomized order. All trials were blindfolded and performed using an isokinetic system at a constant angular velocity of 4°/s (Biodex System 3, Biodex Corporation, Shirley NY, USA) with the subject sitting. The elastic compression sleeve was applied 2 cm below the elbow.

Absolute and variable position errors increased with movement amplitude ($P < 0.05$), but they were systematically lower ($P < 0.05$) with compression sleeves (10, 15, 20 mmHg). Joint position sense was improved to 25, 32 and 33 % for 10, 15 and 20 mmHg, respectively in comparison to without pressure. However post-hoc analysis revealed any difference between compression sleeves. No interaction was observed between pressure and amplitude.

We conclude that compressive sleeves improve passive elbow positioning sense and that this effect is equally present since low pressures. These findings suggest that the stimulation of cutaneous mechanoreceptors with low pressure compressive sleeves could be

useful to enhance proprioceptive acuity. More studies are necessary to understand the role of cutaneous receptors in the joint position sense and beyond in the movement.

THE INFLUENCE OF TRANSVERSUS ABDOMINIS CONTRACTION ON POSTURAL SWAY IN PERSONS WITH AND WITHOUT LOW BACK PAIN.

HENRIKSEN, A., KROSSHAUG, T., BØ, K.

NORWEGIAN SCHOOL OF SPORTS SCIENCES

Introduction: Spinal instability is identified as a possible cause of low back pain (LBP). The transversus abdominis (TrA) has been focused on as an important "stabilizer" of the spine, and the recruitment of TrA is shown to be delayed in subjects with LBP (1). However, based on recent biomechanical studies it has been argued that TrA alone cannot have such a major role as a spine stabilizer (2). Other studies on LBP-patients have shown increased postural sway compared to non-LBP patients, and it has been hypothesised that the increase in postural sway may contribute to the chronification of LBP (3). The aim of the present study was to evaluate whether a voluntary contraction (VC) of TrA influence on the degree of postural sway in standing position in persons with and without low back pain.

Methods: Twenty-five subjects were included in this experimental cross-sectional study, 12 LBP patients and 13 healthy controls. Mean age in the two groups were 26.2 (SD 6.2) and 27.8 (SD 8.7) years respectively. Postural sway was measured as center of pressure (COP)-excursion while standing on foam surface. Measurements for 20 seconds were done on a force platform: 1)eyes open, 2)eyes closed, 3)eyes open and VC of the TrA and 4)eyes closed and VC of the TrA. The VC of the TrA was taught and verified using real time ultrasound (US). Paired samples t-test and independent samples t-test were used for the statistical analysis, and a p-value of <0.05 was considered statistically significant.

Results: When comparing postural sway without and with VC of TrA the healthy controls had a 14 % reduction in both trace-length and velocity with eyes closed ($p = 0.024$, $p = 0.024$). The same trend was seen in the LBP-group with a 7 % reduction of both trace-length and velocity with eyes closed ($p = 0.059$, $p = 0,059$), although not significant. Independent samples t-test with regards to degree of changes when contracting TrA showed no significant differences between the two groups.

Discussion: Contraction of the TrA seems to have some influence on postural sway in standing in healthy subjects. However, this study did not show any close relation between the TrA-muscle function and degree of postural sway in LBP patients, and there were no significant differences between participants with and without low back pain. This study indicates that the role of TrA-contraction may not be as important as previously suggested, but some caution must be taken due to the sample size. Further studies are warranted to understand the role of TrA in stabilization of the spine in standing position.

IS 1 MET REALLY 1 MET?

NISTICÒ, C., AMMENDOLIA, A., IONA, T., PAPAIANNI, M.C., SCARFONE, R.

UNIVERSITY OF CATANZARO

Introduction: The metabolic equivalent (MET) represents the amount of oxygen necessary at the body during rest, it's the equivalent of resting metabolic rate (RMR) and it's equal to 3,5 mlO2•kg-1•min-1 (1 kcal•kg-1•h-1) for every age and subjects. The MET value used in the physical exercise prescription to calculate the energetic cost of several activities as multiple of resting oxygen consumption.

Recent studies have hypothesized that the standard 1 MET value (3,5 mlO2•kg-1•min-1) could overestimate the actual resting oxygen consumption (VO2 resting) and resting metabolic rate (RMR). Our goal was to compare the traditionally accepted value for 1 MET (3,5 mlO2•kg-1•min-1) to direct measures of resting oxygen consumption (VO2 resting) in a group of overweight and obese subjects.

Methods: 22 subjects (3 men and 19 women, mean age 42±12,8), with body mass index (BMI) up to 25,5 kg/m2 (mean BMI 32,6±5,9), have been underwent direct measure of resting oxygen consumption with indirect calorimetry (Fitmate Pro, Cosmed, Italy).

Results: The mean resting oxygen consumption value (VO2 resting) etween BMI and was 2,52±0,54 mlO2•kg-1•min-1, evidently lower than accepted 1 MET value (3,5 mlO2•kg-1•min-1). Furthermore we observed a significant correlation between BMI and VO2 resting (r=-0,534, p=0,005).

Discussion: Established that a correct physical exercise prescription is important an accurate evaluation of the resting oxygen consumption and energetic spending. Our data confirm that in the overweight and obese subjects the standard 1 MET value (3,5 mlO2•kg-1•min-1) determines an overestimation (mean 28,1%) of the real resting oxygen consumption, so an insufficient prescription of the physical exercise. The inverse correlation with the BMI suggests the necessity to individuate a specific correction factor, in order to optimize the results of a protocol of physical exercise with therapeutic aim.

RISK FACTORS FOR THE USE OF MEDICATION IN ELITE ATHLETES

TSCHOLL, P., ALONSO, J.M., JUNGE, A., DOLLE, G., DVORAK, J.

FIFA MEDICAL ASSESSMENT AND RESEARCH CENTRE

Legal and illegal use of medical substances is widespread in international elite sports. Current literature mainly focuses on illegal, hence doping substances. However, concerns about the ample use of painkilling medications, β2-agonists, and antibiotics in top-level athletes have been raised by several authors, since their use, not only when administered in excess, may potentially be harmful under certain circumstances or for certain individuals.

As much as 31 – 51% of the athletes are taking some sort of medication, and 20 – 35% are taking nonsteroidal anti-inflammatory drugs (NSAIDs) prior to competition. Although evidence-based guidelines do not exist for the use of medication and NSAIDs in athletes, the reported results are alarming and might suggest an abuse of legal substances.

The analysis of different sports disciplines highlights several risk factors for the high use of medication in athletes. Team physician and geographic origin have the highest influence. African and Asian athletes were found using half of the medication reported by European and North American track and field athletes. Female athlete – without considering contraceptive medication –, physical demands, age, and competition were other parameters related to increased use of medication. No correlation was found between the intake of medication and success. In professional football players, no difference was found between players participating in the match and substitutes.

The reported use of medication and the gender and geographic differences are difficult to interpret, since current literature does not provide any conclusive evidence. Whether some athletes are overmedicated or undersupplied with medical substances can not be elucidated and therefore need special regard in the future for equal chances in the competition. However, differentiation between indication, wrong application and misuse of prescribed medication is difficult to ascertain. Therefore, it is absolutely essential to establish evidence-based guidelines for the use of medication, especially of painkilling substances in sport.

ENDURANCE AND STRENGHT EXERCISE EFFECTS ON CORTISOL METABOLISM

CALOGIURI, G., MONTARULI, A., ROVEDA, E., SCIOLLA, C., SARTORI, M.L., RAFFAELLI, A., ANGELI, A., CARANDENTE, F.

1. UNIVERSITY OF MILAN, 2. UNIVERSITY OF TURIN, 3. UNIVERSITY OF PISA.

Introduction Intense physical exercise is known to increase the activity of the hypothalamic-pituitary-adrenocortical (HPA) axis. In addition to the widely investigated effects on the HPA axis, physical activity has been shown to modulate glucocorticoid (GC) sensitivity at the target cell level. In recent years, attention has been drawn to 11beta-hydroxysteroid dehydrogenase (11beta-HSD) type 1 and 2 as major determinants of tissue sensitivity to GCs. In the present work we show that intense physical exercise (of either endurance or strenght type) is able to increase acutely systemic 11beta-HSD type 1 activity, and suggest that such an increase represents an early step of the stress response to exercise.

Methods Fifteen healthy, trained males (age: median 29, range 20-36 years, BMI 24.6, 20.7-34.3 kg/m2) were assessed on three non-consecutive days: at rest, during an endurance and a strength sessions. Preliminarily, maximal oxygen uptake (VO2max) and maximal power (one-repetition maximum, 1RM) were assessed. During each session, between 10.00 and 16.00 h, 6-h urine and 4 salivary samples were collected. Urinary total tetrahydrocortisol, tetrahydrocortisone, cortisol and cortisone were measured with HPLC-tandem mass spectrometry; urinary unconjugated cortisol and cortisone were measured by HPLC-UV. Salivary cortisol were measured by RIA and ELISA, respectively.

Results Both endurance and strength exercises caused an increase in tetrahydrocortisol/ tetrahydrocortisone ratio (endurance: mean±SE 1.90±0.07 vs. 1.63±0.06, P<0.01; strength: 1.82±0.05 vs. 1.63±0.06, P=0.03), consistent with increased systemic 11beta-HSD type 1 activity. No relationship was found with age, BMI, VO2max, maximal power load. No significant change was apparent in cortisol/cortisone ratio, an index of 11beta-HSD type 2 activity. No effect of exercise on salivary cortisol was observed, whereas a significant effect of sampling time was found, with cortisol decreasing in the 10.00-16.00h window.

Discussion This study shows that intense physical exercise acutely increases urinary tetrahydrocortisol/tetrahydrocortisone ratio in humans, consistent with increased systemic 11 beta-HSD type 1 activity. Under heavy muscular work, the role of muscular tissue in cortisol generation may become remarkable, due to redistributed blood flow, hence the availability of substrate (cortisone) which is freely diffusible in myocytes from the vascular compartment. Cortisol generation at the tissue level is conceivably an early component of adaptive response to physical exercise, which occurs independently of increased cortisol secretion.

SELF-REPORTED VERSUS DIAGNOSED STRESS FRACTURES IN NORWEGIAN FEMALE ELITE ATHLETES

TORSTVEIT, M.K., OYEN, J., SUNDGOT-BORGEN, J.

UNIVERSITY OF AGDER, UNIVERSITY OF BERGEN, NORWEGIAN COLLEGE OF SPORT SCIENCES

Introduction: The prevalence of stress fractures among female athletes ranges from 4% to 52%. Thorough physical examinations and imaging is recommended for adequate diagnosis of stress fractures. Still, many studies on female athletes use self-reported stress fracture data, and no studies have compared self-reported stress fractures with diagnosed stress fractures in athletes. Furthermore, even

if stress fractures are seen upon as a sport-related injury, also physically active non-elite athletes may theoretically experience such injury. The aims of this study were therefore to determine the prevalence of self-reported versus diagnosed stress fractures in athletes, and to investigate whether stress fractures are prevalent also in the general population.

Methods: A random sample of Norwegian elite athletes from the national teams, aged 13-39 years (n = 186) and a random sample of non-athletic controls (n = 145) in the same age group participated in the study. The athletes represented a junior- or senior team, or a recruiting squad for one of these teams, in one of 46 different sports/events. This was a two-phase study including: 1) a questionnaire, and 2) an interview. The diagnosis of a stress fracture was based on a confirmation of the subjects past stress fracture by plain radiography, nuclear scintigraphy, computed tomography (CT), magnetic resonance imaging (MRI), or a combination of these modalities taken short time after their injury occurred.

Results: A higher percentage of athletes self-reported stress fractures (14.0%) compared to those diagnosed with stress fractures (8.1%) ($p < 0.001$). Six controls self-reported stress fractures, but none of them were diagnosed with stress fractures. The total training volume was higher for the athletes diagnosed with stress fractures (17.0 ± 5.8 hours/week) compared with the athletes without diagnosed stress fractures (13.0 ± 5.5 hours/week) ($p < 0.05$). Nine of the 15 athletes diagnosed with stress fractures represented high impact sports, while six represented medium impact sports. None of the athletes diagnosed with stress fractures represented low impact sports. Eight of the 15 stress fractures were found in the metatarsals.

Discussion: By using a questionnaire to collect stress fracture data, the results consist of what the subjects report that they have experienced or have not experienced. We found that 42.3% of the athletes were classified as false positive subjects (b/(a+b)=11/26). Thus, our results indicate that self-reporting of stress fractures has low validity. Furthermore, all of our non-athletic controls were classified as false positives, which indicate that stress fractures are a sport related injury. We recommend that future studies in this field should be carefully using self-reporting as a measurement method.

VARIATIONS IN EXERCISE LOAD, IMUNOGLOBULIN STATUS AND UPPER RESPIRATORY TRACT INFECTIONS IN ULTRA-MARATHON RUNNERS

PETERS, E.M., SHAIK, J., KLEINVELDT, N.

UNIVERSITY OF KWAZULU-NATAL

Introduction: Few studies that have been able to demonstrate a direct association between a specific measure of exercise-induced impaired immune function and increased incidence of clinically confirmed infection and the aetiology of upper respiratory tract infections (URTI) in endurance athletes, remains uncertain. This study was designed to examine the effect of variation in exercise load over a six-week period on immunoglobulin status in the saliva and blood and the incidence of self-reported URTI symptoms in ultramarathon runners. This included a four-week taper period before and two weeks following participation in a competitive Ultramarathon event.

Methods: Daily training distance and self-reported URTI symptoms were recorded in fourteen male runners registered for a 86.5 km Comrades Marathon during the six-week period before and after the race. Saliva samples were collected at 28, 14 and one day (01PRE) prior to the race, immediately post-race(IPR) and one (01PR), three and 14 days post-race and blood samples at 01PRE, IPR and 01PR. Salivary IgA and IgM concentrations were determined by sandwich ELISA and serum immunoglobulin (IgG, IgM and IgA), leukocyte and cortisol concentrations were adjusted for plasma volume changes occurring following the race.

Results: Initial mean weekly training distance was 89.4 km.week-1 (± 28.9) and mean race finishing time, 9h33 (± 1h02). Absolute (µg.ml-1) and relative (µg.mg protein-1; µg.ml-1) IgA, and IgM concentrations were unaffected by taper in training during the four-week period prior to the ultramarathon ($p > 0.05$). Mucosal IgA and IgM secretion rates ($p = 0.018$; 0.008) decreased significantly and plasma volume adjusted serum cortisol and leukocyte concentration increased ($p < 0.001$) following the race. There were no significant changes in serum IgG, IgM and IgA concentrations at IPR, but serum IgG concentration increased significantly ($p = 0.009$) at 01PR.

No significant association was detected between secretory IgA and IgM concentrations or blood IgG, IgM and IgA status and incidence of self-reported symptoms of pre- or post-race URTI. The maximum incidence of self-reported symptoms of URTI (64%; n = 9) was recorded 7-14 days post-race. Fifty-seven percent (n = 8) of subjects had also reported symptoms at 28-21days prior to the race, while 36% (n = 5) reported symptoms that were indicative of local rhinopharangitis only.

Discussion: Non-infectious inflammatory responses to increased pulmonary ventilation and/or the possible reactivation of viruses which were present during the pre-race period, during the post-race fortnight, are proposed in the aetiology of symptoms of URTI experienced by endurance athletes during the post-race fortnight.

ELECTROMYOGRAPHIC AND KINEMATIC TRUNK ANALYSIS DURING THE STRAIGHT PUNCH.

IZUMI, S., KANEOKA, K., MIYAMOTO, T., OKUBO, Y., HIURA, M., MIYAKAWA, S.

HOSEI UNIVERSITY

Introduction: The contribution of the trunk muscles to spinal stability is well established. However, there is little investigative research about trunk investigating the trunk muscles in sport. The aim of this study was to analyze the electromyographic activity of trunk muscles and the three-dimensional kinematics of the trunk between skilled and novice boxers in the straight punch of the dominant hand.

Methods: The participants who volunteered for this study were fifteen university age males with no history of chronic low back pain. The participants were ranked as experienced (N = 8) or novice (N = 7). We used a surface electromyographic (SEMG) system and a three-dimensional motion analysis system. The straight punch was divided into 3 phases: a primary phase, a throw phase and a return phase. SEMG was used to measure activity in the superficial lumbar multifidus, transverse fibers of internal oblique, external oblique and rectus abdominis. The average-rectifird-value (ARV) electromyographic amplitude for each phase was calculated and normalized to the highest ARV amplitude from a straight punch, which attempted to elicit maximal voluntary isometric contractions (MVIC) for each muscle. The three-dimensional motion analysis was performed calculate the horizontal angle of acromion, anterior superior iliac spine (ASIS) and greater trochanter, respectively. The value which subtracted the angle of ASIS from the angle of acromion and the angle of greater trochanter from the angle of acromion were computed as an acromion / ASIS twist angle and an acromion / greater trochanter twist angle, respectively.

Results: In SEMG, the activity of the non-dominant transverse fibers of internal oblique was significantly greater in the novice boxer than in the experienced boxer at primary phase (experienced: 29% and novice: 130% MVIC). And the activity of the dominant transverse fibers of internal oblique was significantly greater in the novice boxer than in the experienced boxer at throw phase (experienced: 85% and novice: 173% MVIC). In the three-dimensional motion analysis, the results of investigation show differences between experienced and novice

boxers in terms of the horizontal angle of greater trochanter and anterior superior iliac spine. An acromion / greater trochanter twist angle in the novice boxers was larger ($p<0.1$).

Discussion: Since the straight punch of the novice boxer was unfamiliar the transverse fibers of internal oblique in the novice boxers might be larger than in the experienced boxers. The experienced boxers rotated the whole trunk and had struck the straight punch. On the other hand, the novice boxers had struck the punch with twisting of the upper body.

EFFECTS OF JOINT ANGLE ON VOLITIONAL AND MAGNETICALLY-EVOKED NEUROMUSCULAR PERFORMANCE

MINSHULL, C., WILLIAMSON, D., GLEESON, N.P.

NOTTINGHAM TRENT UNIVERSITY

Peripheral magnetic stimulation (MS) has become popular in estimating neuromuscular performance capacity in healthy and in clinical populations to evaluate the effects of exercise and where traditional volitional testing is not appropriate[1,3,4,5]. Indices of knee-extensor volitional and magnetically-evoked neuromuscular performance (N= 8 healthy males; 20.3 ± 0.5 years; 80.0±9.4 kg; 178.4±6.5 cm) were obtained at 3 functional joint angles (25°; 35° and 45° knee flexion; 0° = full extension) that were randomly presented over three days, each separated by 48-hours.

A significant interaction ($F[2,14] = 6.8$ $p<0.05$) associated with repeated-measures (RM) ANOVA showed that magnetically-evoked electromechanical delay (EMDE) values of the vastus lateralis were statistically similar across all joint angles, however, volitional electromechanical delay (EMDV) values were quicker at greater knee flexion angles; EMDV scores at 45° were 25% quicker than at 25°. EMDE values were on average 33% shorter than EMDV at joint positions proximal to full extension (EMDV: 26.2±6.1ms; 24.3±8.7ms vs. EMDE: 17.8±1.2ms; 17.0±1.3ms, at 25° and 35°, respectively). Consistent with the muscle length-tension relationship, a significant interaction ($F[2,14] = 13.8$ $p<0.001$) associated with RM ANOVA showed that volitional peak force (PFV) and magnetically-evoked peak twitch force (PTFE) scores were superior at greater knee flexion angles. However, the relative changes of joint angle on performance were larger for PFV compared to PTFE (PFV: 9.8% and 27.1% greater at 35° and 45° vs. 25°; PTFE: 8.8% and 17.5% greater at 35° and 45° vs. 25°).

The importance of MS is exemplified in the assessment of muscle performance in patients who are unable to maximally activate their muscles[2]. The current results suggest that experimenters must exercise caution when using MS, since joint angle manipulation was associated with differential changes to volitional vs. evoked estimates of performance. Furthermore, indices of magnetically-evoked performance capacity at knee angles proximal to full extension where key ligamentous structures are under greatest strain, may offer an over-estimation of performance capabilities (EMDV vs. EMDE).

PREVALENCE OF ELECTROCARDIOGRAPHIC ABNORMALITIES AND VARIATIONS IN ATHLETES.

GALINDO, M., CALDERÓN, F.J., BUTRAGUEÑO, J., CUPEIRO, R., DÍAZ, V., MORENCOS, E., PEINADO, A.B.

PHYSICAL ACTIVITY AND SPORTS SCIENCE COLLEGE. POLYTECHNIC UNIVERSITY OF MADRID.

The athlete's heart goes through certain adaptations as a consequence of the stimulus of continuous physical exercise training. These adaptations are seen in electrocardiography, which shows certain variations of normality. The aim of this descriptive study is to asses the prevalence of electrocardiographic abnormalities and variations in athletes undergoing a sport-medical examination in the Effort Physiology Laboratory of the Physical Activity and Sports Science College at Polytechnic University of Madrid. Methods: the population in this study includes 52 healthy asymptomatic athletes on a range of age from 14 to 49 years, training different endurance Sports (cycling, running, triathlon, and others), undertaking a sport medical examination including a 12 lead electrocardiography test. Athletes underwent a medical examination; afterwards, the 12 lead electrocardiography recordings were gathered and analyzed in order to value the prevalence of abnormal findings and variations in athletes. The electrocardiographic patterns were evaluated according to commonly used clinical criteria. Results: most frequently electrocardiographic variations found were sinus bradychardia (43,63%), early repolarisation pattern (34,54%), left ventricular hypertrophy signs (16,36%), incomplete bundle branch block (10,90%), first degree atrioventricular block (3,63%), non specific intraventricular conduction delay (3,63%) and left anterior fascicular block (1,81%). 15 individuals (27,27%) were found to have a completely normal electrocardiographic study. In conclusion, electrocardiographic variations in the athlete's heart are very common, however abnormal patterns suggesting cardiac disease has a much lower prevalence.

MORPHOLOGICAL AND MATURITY PROFILE OF YOUNG SOCCER GOALKEEPERS WITH 11-14 YEARS OF AGE

REBELO GONÇALVES, R., SEVERINO, V., GIL, N., COELHO E SILVA, M.J., FIGUEIREDO, A.J.

FACULTY OF SPORT SCIENCE AND PHYSICAL EDUCATION - UNIVERSITY OF COIMBRA. PORTUGAL

Studies regarding young soccer players have been increasing in the last decade. However, studies that associate age-group and field position are missing, particularly the characterization of young soccer goalkeepers. Regarding this limitation the purpose of this study is to define the morphological and maturational profile of young soccer goalkeepers according to their age-groups.

The sample consisted of 17 male soccer goalkeepers included in two age groups: 11-12 (n=8) and 13-14 (n=9) years-old. For morphological profile were included the following variables: height, weight, arm span, body mass index (BMI), bicristal/biacromial ratio, sitting height/height ratio, adiposity (sum of four skinfolds – tricips, subscapular, suprailiac and calf). Somatotype (Carter & Heath, 1990) was calculated. Maturation was assessed through somatic indicators such as maturity offset (Mirwald et al., 2002) and percentage of predicted adult height (%PAH – Khamis & Roche, 1994).

In sequence by age-group, 11-12 and 13-14 years old, respectively, the following trends were noted: Chronological age (12.0, 14.2) height (147.9, 166.9); weight (42.9, 59.8); arm spam (147.5, 171.5); BMI (19.43, 21.24); bicristal/biacromial ratio (72.8, 73.1); sitting height/height ratio (51.0, 50.6) and adiposity (42.0, 33.4). In both somatotypes mesomorphism is the most representative category (3.4-4.7-2.9, 2.3-4.4-3.3). However the 11-12 years-old group has a higher value for endomorphism and the 13-14 age-group a higher value for ectomorphism. Looking at the mean values for the maturational indicators, the maturity offset (-2.02, 0.15) shows that the 13-14 years-old players have already cross the peak height velocity, being this difference in the maturity process corroborated by the %PAH (84.9, 91.6).

Malina et al., 2004 found similar results for height and weight in young soccer players for different field positions (defense, midfield and forward). This suggests that, at these ages, the morphological profile of young soccer goalkeeper is not different from that shown by other players in different positions. However more studies regarding the characterization of young soccer goalkeepers using a more extensive pool of variables are needed.

HEMOGLOBIN AND HEMATOCRIT VALUES DUE TO TWO DIFFERENT MEASUREMENT SYSTEMS

ACHTZEHN, S., SPERLICH, B., DE MARÈES, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: The measurement of hemoglobin (Hb) and hematocit (Hc) is of great interest to exercise science as well as in high performance sport. Especially the effect of high altitude training is presented trough Hb and Hc measurement. High Hb concentrations measured in athletes during competitions can have profound consequences to them. From this point, the measurement of hematological parameters needs to be at high quality. But unfortunately it is not always possible to use the same devices to control these parameters or to document time series. The aim of the study was to detect inter-device variability in the measurement of Hb and Hc.

Methods: For this, blood samples of 95 athletes where measured with two different devices: KX-21N, Sysmex (A), Germany and ABX Micros 60 (B) from Horiba, France. The results were classified (device A as reference method) and absolute value differences were demonstrated. Mean differences of Hb and Hc classes were statistically calculated.

Results: With device A the lowest Hb of 11.2 g/dl and highest of 17.0 g/dl was measured. The range from device B ranged from 10.8 g/dl to 15.3 g/dl. The average of the value differences is 0.6 g/dl with a standard deviation of 0.6 g/dl. For example Hb (g/dl) of 15.6 (A) vs. 13.4 (B) an 17.0 (A) vs. 14.9 (B) were found. Although the correlation of the two devices is high (r=0.88) significant statistical differences in all Hb-classes between the two devices were found (p=<0.001). Device B shows systematically lower values. The differences of Hc values (%) seems to be lower and the correlation is very high (r=0.96). Also, the mean differences are significant (p=<0.05).

Discussion: The data collected in this study shows that it is necessary to detect the measurement variability between devices. Further, it is important to define a standardized method/machine for the determination of Hb and Hc concentration which can to be used for blood profiles or anti doping testing.

HYDRATION AND SWEATING RESPONSES TO HOT WEATHER FOOTBALL COMPETITION

SHIRREFFS, S.M., MAUGHAN, R.J., OZGÜNEN, K.T., KURDAK, S.S., ERSÖZ, G., BINNET, M.S., DVORAK, J.

LOUGHBOROUGH UNIVERSITY (LOUGHBOROUGH, UK), ÇUKUROVA UNIVERSITY (ADANA, TURKEY), ANKARA UNIVERSITY (ANKARA, TURKEY), F-MARC (ZURICH, SWITZERLAND)

Introduction: Football is played worldwide and takes place in a variety of environmental conditions. Competitions are often held in environments which differ from the conditions that players typically experience. The aim of this study was to investigate hydration and sweating responses of players during a match played in hot weather conditions.

Methods: Twenty-two males completed a FIFA-regulation football match in 34.3±0.6oC, 64±2% relative humidity. On arrival at the stadium, ~45min prior to the match start, players emptied their bladder and the specific gravity of the urine (Usg) was determined by refractometry. Then from 30-15min prior to the match start all players were weighed to the nearest 20g on an electronic balance when wearing only underwear. Immediately after being weighed players were prepared for sweat sample collection (Maughan et al 2007). Sweat collection patches were removed at half-time and samples were analysed for sodium and potassium concentration by flame photometry. On match completion players were reweighed wearing only underwear within 15min of the match end. During the match players had access to drinking water via individually numbered bottles. Drinking was neither encouraged nor discouraged during the match and players were left to behave as they wished with regards to drinking. All drink bottles were weighed on electric scales measuring to the nearest 1g, prior to and at the end of the match to determine the volume consumed by each player. Data are presented as mean±SD.

Results: Pre-match Usg (1.011±0.006) indicated that players started the match in a euhydrated state. Players lost 1.51±0.64kg over the duration of the match ranging from a gain of 0.12kg to a loss of 2.92kg. This is equivalent to a body mass loss of 2.2±1.0%. Players drank 1653±487ml, so their estimated sweat volume was 3.1±0.6l. Sweat sodium concentration was 45±9mmol/l and potassium concentration 3.5±0.4mmol/l. This translated into losses of 139±39mmol of sodium or ~8.1±2.3g of salt.

Discussion: Although Usg indicated that most players started the match in a euhydrated state (<1.020; Sawka et al, 2007), individual data indicated that two players presented with pre-match USg greater than 1.020 which may be indicative of hypohydrateion.

It is clear that some players developed significant hypohydration over the course of the match, and it would be predicted that their performance would be reduced. None-the-less, because of the high sweat rates in some players (in the order of 2.5l/h) these individual are unlikely to be able to prevent the development of hypohydration with the current match format.

NO EFFECT OF MUSCLE FIBER TYPE ON MECHANICAL EFFICIENCY DURING CYCLE EXERCISE AT 1.5 HZ

MEDBØ, J.

NATIONALE INSTITUTE OF OCCUPATIONAL HEALTH

Background: There are conflicting views on the effect of muscle fiber type on mechanical efficiency during exercise. Former studies have possible experimental shortcomings that may have influenced their conclusions. Therefore, in properly standardized experi-ments, the mechanical efficiency has been determined for 23 healthy young men with different proportions the two main fiber types to study possible effects of muscle fiber type on efficiency during cycle exercise.

Methods: Each subject cycled for 10 min at in average 19 different powers ranging from 1.0 to 4.6 W/kg (70–370 W) while the pedaling frequency was kept constant at 1.5 Hz. The rate of energy release was determined from the steady state O2 uptake measured near the end of each 10 min exercise period. Delta efficiency was taken as the inverse of the slope of regression of O2 uptake on power (dP/dnO2). Gross effi-ciency at 3 W/kg was established, and finally, the efficiency was taken from each subject's slope of O2 uptake versus power using a common, fixed Y-intercept. Several muscle biopsies were taken from the lateral portion of the knee extensor muscle of each subject, and muscle fibers were classified as type 1 or type 2.

Results: The proportion of type 1 fibers was 0.50 ± 0.13 (mean ± s), delta efficiency was 0.262 ± 0.010, and gross efficiency was 0.213 ± 0.005. There was no significant correlation between any efficiency measure and the proportion of type 1 fibers. A two-sided 95% confidence interval on the data suggests that if the efficiency of the two fiber types differed, the differ-ence was less than 12%. For the same subject the efficiency did not differ more than a few percents between low powers where type 2 fibers may be little engaged and high powers where both fiber types are active.

Conclusion: The data support the idea that the efficiency does not differ between type 1 and type 2 fibers during cycling at 1.5 Hz.

ADIPONECTIN RESPONSE TO MAXIMAL CYCLING EXERCISE IN ELITE MALE CYCLISTS

LAKHDAR ATTIA, N.

FACULTY OF MEDECINE

Introduction: Less is known about the effects of acute exercise on adiponectin concentrations (Simpson and Singh, 2008). Few studies have investigated the adiponectin response to acute exercise in trained subjects (Jurimae et al., 2005; 2006). Actually, two trials reported significant delayed increases (30 min) in adiponectin concentrations (Jurimae et al. 2005; 2006). The aim of the present study was to analyse the effects of acute maximal exercise followed by 60 minutes of recovery on plasma concentration of adiponectin, insulin and glucose in elite male cyclist.

Methods: Eleven elite male cyclists participated in this study (mean and SD) (age : 19.82 ± 4.67 years; body mass: 65.64 ± 6.09 kg; height: 176.82 ± 7.19 cm; BMI : 20,97 ± 1.35 kg.m-2; VO2max: 59.68 ± 4.85 ml.min.kg-1). Subjects performed maximal cycling exercise followed by 60 minutes passive recovery. Blood samples were obtained before, at the end and after 30 and 60 min of recovery.

Result: Adiponectin concentrations were unchanged after exercise and during recovery. However, insulin concentrations were significantly lowered during recovery (-13.66, $P<0.05$ after 30 min recovery and -77.57, $P<0.01$ after 60 min recovery). In the other hand, plasma glucose rose after 30 min of recovery (26.90, $P<0.01$).

Discussion: The present study indicated that acute exercise failed to induce significant changes in adiponectin concentrations in elite trained subjects. These results were confirmed by several other studies (Punyadeera et al., 2005, Jamurtas et al., 2006). Hyperglycemia was associated with hyperinsulinemia soon after a brief bout of exercise greater than 85% of VO2max (Kreamer et al., 2003). Further, there is evidence that insulin is an inhibitor of adiponectin gene expression (Fasshauer et al. 2001), yet with an increase in circulating insulin concentrations in the present study, no discernible changes in adiponectin were observed. Our results suggested that acute maximal exercise not stimulate the production and the release of adiponectin during 60 min recovery post-acute exercises. Furthermore, it appears that after acute maximal exercise adiponectin is not associated with insulin and/or glucose modifications in elite cyclists.

NON-LINEAR INCREASE IN RPE DURING CONSTANT LOAD EXERCISE TO VOLITIONAL EXHAUSTION

RENFREE, A., GURNEY, T.

UNIVERSITY OF WORCESTER

It has been proposed that during constant load exercise to exhaustion, the increase in RPE throughout is linear and that termination usually occurs prior to attainment of the highest possible RPE score (Noakes 2004). This suggests that the rate of increase in RPE during constant load exercise, in addition to the highest RPE that can be sustained, determines the duration that a constant workload can be maintained for. This study models the increase in RPE during constant load exercise to exhaustion at supra lactate threshold intensity using both the Borg Category (C20) and Category-Ratio (CR10) scales.

Ten recreationally active male participants performed an incremental exercise test on an electronically braked cycle ergometer to allow visual identification of the workload that coincided with the lactate threshold (LT). Participants then performed two trials to volitional exhaustion at a workload 60W above LT. RPE was recorded at 60s intervals using either the C20 or CR10 scale. Participants were familiarised with the scales in advance, and the order was randomised. For both scales, RPE data was subsequently scaled as a percentage of total exercise duration for each participant.

Total exercise duration was similar regardless of whether participants reported RPE using the C20 (16.7+5.3min) or CR10 (17.1+8.1min) scales (P>0.05). During every individual trial, participants reported achieving maximum possible RPE regardless of the scale used. When reporting RPE using C20, termination coincided with achievement of maximal RPE in 30% of participants. When reporting RPE using CR10, on no occasion did termination coincide with achievement of a maximal RPE. As a group, participants spent 17+14.2 % of total exercise duration at maximal RPE when using the C20 scale, and 21 +12.0% when using the CR10 scale.

These results suggest that in recreationally active participants, the rate of increase in RPE during constant load exercise is not linear and that termination does not always coincide with attainment of the highest possible values. Therefore, regardless of the RPE scale used, the findings of this study disagree with the contention of Noakes (2004) that RPE is the real determinant of the fatigue point during prolonged sub maximal exercise at a fixed work rate. It is possible, however, that the observed relationship between RPE and termination of exercise may depend to some extent on the training status and experience of participants in these studies.

TASK FAILURE DURING HIGH-INTENSITY EXERCISE IS ASSOCIATED WITH A CRITICAL REDUCTION IN TISSUE OXYGENATION

BISHOP, D., BORTOLOTTI, S., FERRI, A.

UNIVERSITÀ DEGLI STUDI DI VERONA

Introduction: Task failure is an important feature of performance, ageing and many diseases. Three popular models suggest that task failure may be due to: a) a failure of skeletal muscle motor unit recruitment (1); b) depletion of a fixed, critical, muscle energy store (2); or c) a critical reduction in tissue oxygenation (3). The purpose of this study was to assess the hypothesis that task failure during high-intensity, whole-body exercise may be associated with a critical reduction in tissue oxygenation.

Methods: Six well-trained cyclists (VO2max: 67.6 +/- 6.3 mL/kg/min) performed an incremental test to exhaustion on a cycle ergometer. They then performed a familiarisation session, followed by, in a random order, constant-load exercise tests at 100, 110 and 120% of VO2max until task failure. During these trials, near-infrared spectroscopy (NIRS) was used to monitor changes in the concentration (μM) of oxygenated haemoglobin (Hb) and myoglobin (Mb) (delta[02Hb]), deoxygenated Hb+Mb (delta [HHb]) in the right vastus lateralis muscle and the frontal cerebral cortex. Oxygen uptake (VO2) and rating of perceived exertion (RPE) were also monitored during all 3 trials. The study had ethics approval and all subjects signed a statement of informed consent prior to the study.

Results: At task failure, there was no significant difference between the three conditions for delta[HHb] (40 +/- 5 vs 39 +/- 8 vs 37 +/- 7 μM; P>0.05), delta[02Hb] (23 +/- 5 vs 26 +/- 6 vs 22 +/- 3 μM; P>0.05), VO2 (67.6 +/- 4.5 vs 67.4 +/- 3.8 vs 64.7 +/- 4.1 mL/kg/min) or RPE (20 vs 20 vs 20; P>0.05). There were also no significant differences between trials for cerebral oxygenation levels.

Discussion: Our delta[02Hb] and delta[HHb] values, for both the right vastus lateralis muscle and the frontal cerebral cortex, are similar to those previously reported in the literature (3). We report for the first time however, that task failure during 3 different exercise intensities occurred at similar tissue oxygen (and oxygen consumption) levels. While further research is required, our results raise the possibility that task failure during high-intensity exercise (at sea level) may be associated with an inability to further increase the rate of aerobic energy supply.

CARBOHYDRATE SUPPLEMENTATION PREVENT PROTEIN METABOLISM IN A LONG DISTANCE MOUNTAIN BIKE TREADMILL

MOTA, M.P., SOARES, J., TEIXEIRA, R., JOÃO, P.

UNIVERSIDADE DE TRÁS-OS-MONTES E ALTO DOURO

Introduction: As a consequence of its intensity and duration, Mountain Bike (MTB) can induce an increase in serum urea concentration as the final product of protein metabolism. This may be explained by the significant reduction in muscle glycogen with the duration of the event. In order to prevent muscle glycogen depletion and afterward protein metabolism, we searched if carbohydrate ingestion during a long distance MTB treadmill can prevent protein metabolism.

Methods: Ten male athletes aged between 15 and 46 yrs took part in this study (average=32±8.7 yrs). All the subjects performed a 59.14 km MTB treadmill in 5.71 hours (±0.76) during which a carbohydrate supplementation (glucose concentration of 0,7g/Kg/h) was given to each athlete and heart rate was monitored through Polar S625X.

Results/Discussion: Bearing in mind heart rate data, our results revealed that the MTB treadmill was performed with an average intensity of 82.4%. Although relative values of serum urea concentration were significantly increased (15.55%; p=0,012) at the end of the MTB

treadmill, in what concerns to absolute values (22.79 and 26.36 mg/dl respectively before and after the MTB treadmill), they remained normal. The results of this study pointed out for a contribution of protein metabolism to energy production in MTB events of long distance that could be prevented by an adequate carbohydrate supplementation.

EFFECTS OF STATIC STRETCHING ON PROLONGED INTERMITTENT EXERCISE PERFORMANCE

MIYAHARA, Y., MIEDA, K., EBASHI, H.

UNIVERSITY OF EAST ASIA

PURPOSE: The purpose of this study was to investigate effects of static stretching on prolonged intermittent exercise performance. METHODS: Eight male university football players (age; 20±1 yr, height; 172.5±5.3 cm, weight; 65.6±4.9 kg, mean±SD) participated in this study. They completed two 30min intermittent pedaling exercises with a 10min interval under three experimental conditions (passive rest (PR), active rest (AR), and static stretching (SS)). The intermittent exercise protocols consisted of thirty sets, each set including 5-s maximal sprint against a resistance of 7.5% body mass, 25-s active recovery, and 30-s passive rest. During the maximal sprint, peak-pedaling frequency, mean power output, and mean power rate against peak power were evaluated and mean values of 30 sets were used for analysis. Rate of perceived exertion (RPE) and blood lactate concentration (La) were determined at rest, 10, 20, and 30th set during the first intermittent exercise, five and ninth min in the interval, and 10, 20, and 30th set during the second intermittent exercise. In addition, a recovery rate of La was calculated as follows: La recovery rate = (mean La at the first intermittent exercise – mean La at the interval) / (mean La at the first intermittent exercise - La at rest). In the interval between exercises, subjects were performed three treatments as follows; 6min PR, 6min AR or 6min SS. For PR, subjects were required to sit the chair in a relaxed position for 6min. For AR, subjects performed light pedaling on a cycle ergometer (10%load of 0.075kp/kg) at 50rpm for 6min. For SS, thigh (hamstrings and quadriceps) and hip were stretched to the point where they perceived discomfort. During the SS, subjects held at the stretch position for 30s and repeated it two times for each leg. The experimental conditions order was randomly assigned on three non-consecutive days, to rule out order effects. RESULTS: La was significantly decreased by all treatments but the La recovery rate did not different among conditions (PR; 31.6±15.2%, AR; 42.4±21.5%, SS; 39.3±13.5%). Peak pedaling frequency and mean power were not altered by any conditions (peak pedaling frequency: PR; 163±10, 162±11rpm, AR; 161±6, 160±8rpm, SS; 164±10, 164±10rpm, mean power: PR; 675.3±100.1, 672.1±94.2W, AR; 657.2±73.2, 663.9±83.5W, SS; 672.8±92.0, 685.8±88.0W). Mean power rate significantly increased after SS ($p < 0.05$) whereas PR and AR produced no changes in mean power rate (PR; 85.8±5.1, 86.0±5.2%, AR; 85.2±4.5, 86.0±4.4%, SS; 85.0±3.0, 87.0±3.2%). CONCLUSIONS: The SS may increase the prolonged intermittent exercise performance although the SS does not facilitate La removal.

PREDICTION OF MAXIMUM AEROBIC POWER AND MAXIMUM POWER OUTPUT FROM THE RESULTS OF 30-S ANAEROBIC WINGATE TEST

VODICKA, P., HELLER, J.

FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY,

Introduction: Laboratory exercise testing in athletes is based on aerobic and anaerobic tests. In general, aerobic exercise tests are time consuming and demand for highly sophisticated equipment, e.g. gas analysers and ventilometers that should be precisely calibrated. Contrary to this, anaerobic exercise test are usually less time consuming and based on relatively simple principles. The aim of the study was to verify the possibility to predict the main parameters of aerobic tests from the results of anaerobic exercise test, i.e. 30-s Wingate test.

Methods: Altogether 152 top league ice-hockey players (age: 25.96 +/- 4.72 (SD) years; mass: 87.73 +/- 8.17 kg; height: 182.4 +/- 5.7 cm) participated in the study. They were examined at the end of preparatory period before the season. In the same day they were tested by a 30-s Wingate test at a resistance 6 W.kg-1 (=0.104 kg.kg-1), and after 2-hour-lasting recovery break they were loaded by the stepwise maximum cycle ergometry. The statistics included multiple stepwise linear regression analysis using SPSS statistical package. Age, body mass, height, fat-free mass, and Wingate test results were considered independent variables whereas maximum aerobic power (VO2max) and maximum power were considered dependent variables. As peak blood lactate concentration (LA) in the Wingate test is sometimes (but not as a standard) included to the results of the Wingate test, the results were computed both with and without LA as an independent variable.

Results: Pmax [W] = 351.227 + 0.322*Pmin [W] – 2.867*MP/PP [%] + 0.880*Age [y]

r= 0.685; SEE= 25.159; sign. 2.976E-20

Pmax/kg [W.kg-1] = 9.016 – 0.055*Body mass [kg] – 0.004*Pmin [W] – 0.039*MP/PP [%] + 0.012*Age [y]

r= 0.694; SEE= 0.287; sign. 3.559E-20

VO2max [l.min-1] = 0.487 + 0.003*Pmin [W] + 0.015*Body mass [kg] + 0.053*LA [mmol.l-1]

r= 0.662; SEE= 0.372; sign. 1.750E-18

VO2max [l.min-1] = 1.375 + 0.003*Pmin [W] + 0.015*Body mass [kg]

r= 0.641; SEE= 0.380; sign. 7.453E-18

VO2max/kg [ml.kg-1.min-1] = 36.437 + 2.935*Pmin/kg [W.kg-1] - 0.166*Body mass [kg] + 0.603*LA [mmol.l-1]

r= 0.539; SEE= 4.301; sign. 4.972E-11

VO2max/kg [ml.kg-1.min-1] = 47.670 + 2.797*Pmin/kg [W.kg-1] - 0.174*Body mass [kg]

r= 0.506; SEE= 4.388; sign. 2.621E-10

Discussion: Regardless the substantial differences in the nature of the aerobic cycle ergometer test and anaerobic Wingate test the results had demonstrated the possibility to predict the parameters of aerobic tests from the results of the 30-s Wingate test. The standard errors of the estimate obtained form these equation seem to be considerably low and therefore acceptable, however coefficients of correlation (r) ranging 0.506 to 0.694 and/or coefficient of determination (R2) 0.256 to 0.482 may limit the predictive validity of VO2max and Pmax from the Wingate test Results: References

COMPARISON OF SLEEP BETWEEN ATHLETES RUNNING SEVEN MARATHONS ON SEVEN CONTINENTS IN SEVEN DAYS (7MM)

GAMBLE, D., GLASGOW, P., JENNINGS, D., MADIGAN, S., WEBB, M.

SPORTS INSTITUTE NORTHERN IRELAND

The completion of seven marathons, on seven continents, in seven consecutive days involved circumnavigating the globe, travelling more than 35,000 miles, through 24 different time zones and required substantial physical and psychological endurance. Intercontinental travel results in the disruption of normal circadian rhythms and is associated with fatigue and a range of symptoms, commonly referred to as jet lag. Disturbance in the sleep-wake cycle is of particular concern as appropriate sleep is vital to promote the recovery process post-exercise and facilitate subsequent physical performance. Exposure to day light is required to facilitate re-entrainment of circadian rhythms. Thus the disruption in sleep may be exacerbated in a visually impaired (VI) athlete.

PURPOSE: To compare the quantity of sleep achieved between a VI athlete and his guide (N) runner during an extreme endurance challenge.

METHODS: Sleep was possible during the 63 h and 40 min of total flight-time and 19 h 20 min of hotel visits. Sleep was measured using a body monitoring device, which was placed on the right tricep of each runner throughout the duration of the challenge. A classification algorithm incorporating structured statistical measures from aggregated observations was used to detect sleep. This involved evaluation of instantaneous agitation and sequences of motion, differential and proportional changes in heat-flux and skin temperature, the galvanic skin response and the proximity to motion signatures. Comparisons in the quantity of sleep obtained between each marathon were made using a one-way ANOVA.

RESULTS: The mean quantity of sleep achieved was 3 h 20 min + 1 h 23 min (range 1 h 0 min – 4 h 45 min) vs 5 h 27 min + 2 h 18 min (range 2 h 26 min – 7 h 26 min) for the VI and N runner, respectively. There was a subsequent difference in the total amount of sleep achieved, 19 h 58 min (VI) compared to 32 h 41 min (N). Although there was evidence of a disparity in the quantity of sleep achieved, this difference was not significant ($P>0.05$).

CONCLUSION: This study indicates that the VI athlete experienced greater difficulty initiating and maintaining sleep throughout this extreme challenge. This information may be relevant for practitioners developing preparation strategies for visually impaired athletes requiring travel through multiple time zones to competition venues.

COMPARISON OF VO2 KINETICS IN WALKING AND RUNNING AT THE 'ENERGETICALLY OPTIMAL' GAIT TRANSITION SPEED

SENTIJA, D.

FACULTY OF KINESIOLOGY, UNIVERSITY OF ZAGREB

Background: The metabolic costs for walking and running intersect at a speed (termed the energetically optimal transition speed, EOTS) that is significantly higher than the preferred gait transition speed (Hreljac 1993; Brisswalter and Mottet 1996; Tseh et al. 2002). None of the studies to date, considered the influence of a slow component of VO2 kinetics for walking and running in the determination of EOTS.

Purpose: The aim of this study was to examine VO2 kinetics during walking and running at the energetically optimal gait transition speed (EOTS).

Methods: Twenty-two physical education students (21.4±2.4y, 182±7cm), performed three incremental treadmill tests for determination of EOTS, the aerobic gas exchange thresholds (for walking, ATw, and running, ATr) and VO2max. Thereafter, they completed two square-wave 30-minute walking (W30) and running (R30) tests at the EOTS; VO2 was determined breath-by-breath, and computorised non-linear regression techniques were used to describe either a mono-, bi- exponential or exponential+linear VO2 response. ANOVA for repeated measurements was used to test for differences between walking and running parameters.

Results: The VO2 and speed of locomotion at the EOTS were 32.8 ml/kg and 8.2±0.2 km/h, respectively. Four subjects had to discontinue the W30 test before completion, due to fatigue and pain in the shins. All W30 tests were distributed within the heavy and very heavy intensity domains, while all R30 tests were distributed within the moderate and heavy intensity domains. The time constant for the fast VO2 component (tau1) in the 30-minute tests was significantly smaller for running than for walking (29.0±9.1 s vs 33.7±9.8 s, $p<0.01$), while the amplitudes of the primary VO2 response (A1) did not differ (18.1±1.9 vs 17.9±1.9 ml O2/min/kg). The VO2 slow component was greater for W30 than R30 (275±220 ml/min vs 146±104 ml/min, $p<0.05$) and more often present (22/22 vs 19/22). A steady-state VO2 was reached by 12/22 subjects in the W30, and by 18/22 in the R30 test. The aerobic energy cost derived from VO2 centered at the 3rd minute of exercise (C3) was significantly lower than the one derived from the steady-state VO2 (Css) in both, W30 (187±17 vs 208±23 ml O2/kg/km) and and R30 (188 vs 199±17 ml O2/kg/km) ($p< 0.05$). Only in the R30 test, C3 explained effectively the variability of Css ($r2 = 0.94$ and 0.50, for R30 and W30, respectively).

Conclusions: Current methods used for EOTS determination are inadequate, as the slow component of the VO2 kinetics has to be considered. The VO2 kinetics (tau1) are significantly faster in running compared to walking at the energetically optimal gait transition speed in young, healthy subjects. Pain located in the shin region may cause an increased perception of local effort, and cause exhaustion in less than 30 min of walking at the EOTS.

EFFECTS OF PRIOR EXERCISE USING REMOTE MUSCLE GROUPS ON INDICES OF AEROBIC FUNCTION AND THE POWER-TIME RELATIONSHIP

JOHNSON, M., SHARPE, G.R., BROWN, P.I.

NOTTINGHAM TRENT UNIVERSITY

The tolerable duration of high-intensity exercise is described by a hyperbolic function of the power output, whose asymptote and curvature constant denote critical power (CP) and anaerobic work capacity (W'), respectively. W' has been described as a finite intramuscular energy store that is utilised when exercise intensity exceeds CP (Ferguson et al. 2007). Alternatively, exercise intolerance above CP may result from the accumulation of fatigue-inducing metabolites at a rate proportional to the rate of W' utilisation. We therefore examined the

effects of metabolite accumulation, achieved by prior exercise using remote muscle groups, on responses to incremental cycling exercise and the power-time relationship.

Five recreationally active males performed a maximal incremental cycling test (20 W/min, starting at 20 W) and four exhaustive constant power tests (exercise duration: 3-15 min) to determine the hyperbolic power-time relationship. The battery of cycling tests was then repeated following prior high-intensity intermittent arm-cranking exercise comprising 8 x 1 min exercise bouts, interspersed by 30 s rest intervals, at an intensity of 1.5-2.0 W/kg body mass. Upon completion of the arm-cranking exercise subjects transferred to the cycle ergometer and rested for 4 min before performing the prescribed cycling test. Arterialised venous blood was sampled from a dorsal hand vein.

Compared to rest the arm-cranking exercise performed prior to the incremental test caused a reduction in blood pH (mean (SD)) (7.400 (0.001) vs. 7.256 (0.018), P<0.01) and an increase in blood lactate concentration ([La]B) (0.78 (0.35) vs. 9.59 (1.15) mmol/L, P<0.01); similar changes were observed when arm-cranking exercise preceded constant power exercise. [La]B following the incremental test (11.04 (1.70) mmol/L) was not different from that measured when the test was preceded by arm-cranking exercise (9.39 (1.48) mmol/L), although blood pH was lower (7.232 (0.024) vs. 7.293 (0.023), P<0.05). Prior arm-cranking exercise caused reductions in the aerobic gas exchange threshold determined using the v-slope method (oxygen uptake = 2.95 (0.48) vs. 2.08 (0.35) L/min) and maximal values for cycling power (350 (29) vs. 318 (31) W, P<0.01), oxygen uptake (4.19 (0.64) vs. 3.47 (0.41) L/min, P<0.05), and minute ventilation (160.4 (20.7) vs. 139.7 (36.4) L/min, P<0.01). CP was unaffected by prior exercise (268 (25), SEE = 1 (1) vs. 260 (29), SEE = 3 (1) W), whereas AWC was reduced (13.5 (3.1), SEE = 0.8 (0.4) vs. 10.3 (2.0), SEE = 1.3 (0.6) kJ, P<0.05).

In conclusion, our data suggest that metabolite accumulation resulting from prior exercise using remote muscle groups causes reductions in several indices of aerobic function during incremental exercise. The reduction in W' due to prior exercise using remote muscle groups also supports the notion that W' reflects, in part, metabolite accumulation to a critical level.

CARDIOVASCULAR AND THERMOREGULATORY RESPONSES TO PROLONGED EXERCISE IN HOT-DRY AND HOT-HUMID CLIMATIC CONDITIONS

THOMPSON, M.W., CHE MUHAMED, A.M.

THE UNIVERSITY OF SYDNEY, UNIVERSITY OF MALAYA

Introduction: Sweat evaporation plays a critical role in maintaining body temperature during exercise in the heat. During intense prolonged exercise sweat production may exceed 2 L.hr-1 resulting in a significant body water deficit. In a hot-dry environment most of the sweat produced is evaporated. However in a hot-humid environment the small difference in vapour pressure between the skin surface and surrounding environment limits evaporative heat loss. The resulting skin wettedness has been associated with the phenomenon of hidromeiosis, whereby sweating is reduced in humid conditions. This study examined whether sweat rate was impaired with prolonged exercise in a hot-humid (HH) condition.

Methods: Eleven un-acclimatised male distance runners (age: 36±9 yrs; VO2max: 63±6 ml.kg -1.min-1) were randomly assigned to undertake treadmill running exercise in a climate chamber for 60 minutes at 70%VO2max in a hot-dry (HD, 30oC and 20%rh) and a HH (30oC and 70%rh) condition. A rectal temperature probe and 4 skin thermocouples provided continuous monitoring of body core temperature and skin temperatures. Change in bodyweight provided an estimate of sweat rate. Heart rate was measured continuously via heart rate telemetry and respiratory gas exchange and cardiac output (CO2 rebreathing method) measures were taken at 10, 30 and 60 minutes.

Results: Both rectal temperature (Tre) and mean skin temperature (Tsk) were significantly (P<0.05) higher post exercise in the HH compared with the HD environment (Tre 39.5  0.3oC vs. 38.7  0.3oC; and Tsk; 33.2  0.8oC vs. 31.7  0.9oC, respectively). While the skin surface area was fully saturated (ω ≥ 100%) in the HH condition, there was no significant difference between the HH and HD condition in sweat production (49.1 ± 5.5 g.min-1 and 47.0 ± 4.9 g.min-1 respectively). Thermal comfort (TC) and perceived exertion (RPE) ratings showed that subjects felt warmer and found exercise more difficult to perform in the HH environment compared with the HD trial (TC: 15  3 vs. 13  3, respectively; and RPE: 6.7  0.5 vs. 5.8  0.9, respectively). There was a significant (P<0.05) increase in VE in HH compared with HD at 60minutes, while there was no difference between all other respiratory exchange measures. Heart rate steadily increased in both HH (+21bpm) and HD (+16bpm) to reach 92%HRmax and 90%HRmax respectively. Cardiac output remained constant (20 – 21 L.min-1) in both conditions over time.

Discussion: This study has shown that the drive for sweating is maintained in well trained endurance runners undertaking prolonged exercise in HH conditions, despite considerable skin wettedness. Although we were unable to quantify the sweat drippage that occurred in the HH condition, the significant increase in rectal temperature in this condition suggests that a volume of sweat produced was ineffective in terms of heat dissipation. The upward drift in VE and HR in the HH condition is a typical response associated with an elevated body temperature.

HEAT ACCLIMATION AND ACTIVATION OF A CYTOPROTECTIVE PATHWAY

FATSEAS, G.

THE UNIVERSITY OF NEW SOUTH WALES

Heat acclimation and activation of a cytoprotective pathway

George Fatseas1, David Simar1, Corinne Caillaud2

1 School of Medical Sciences, Faculty of Medicine, University of New South Wales, Sydney NSW 2052 Australia

2 Faculty of health science, The University of Sydney, Cumberland Campus, Lidcombe NSW 1825, Australia

Animal studies have shown that heat acclimation (HA) is neuro-protective against traumatic brain injury, and provide cardio-protection, following an ischaemic attack. The pathways associated with HA and its protective nature, have been found to be linked in animals with the induction of hypoxia inducible factor 1α(HIF-1α) and heat shock protein 72(Hsp72). HA has also been shown to upregulate Epo receptor (EpoR), a target gene for HIF-1α, providing neuron and myocardium protection in animals. However, whether similar protective adaptations to HA occur in humans is yet to be confirmed. The aim of this study was to investigate the impact of HA on HIF-1α and Hsp72 induction and their effect on EpoR regulation in human subjects. We hypothesise that HA will upregulate HIF-1α and Hsp72 and this upregulation will increase EpoR expression.

To test this hypothesis, healthy, highly trained male cyclists/triathletes, with a mean age of 30.26±7.49 yrs and a VO2max of 58.55±5.91 ml/kg/min, were randomly assigned to a heat group (HG = 10 subjects) or a neutral group (NG = 11 subjects). Aerobic fitness and acute exercise have been shown to impact on Hsp72 and HIF-1 regulation. In an effort to limit the impact of these potentially confounding factors, only highly fit subjects were recruited and maintained the same level of training during the HA. Subjects in HG trained for 6 consecutive days on a bike for 1 hour per day at 70% of their VO2max, in 35° C and 40% humidity. Subjects in NG performed the same training sessions at 22° C and 40% humidity. Venous blood samples were collected at rest, and 60 minutes into recovery following the 1h exercise. Flow cytometry was used to assess levels of HIF-1α, Hsp72 and EpoR expression in monocytes at the various time points.

There was no significant difference between the 2 groups before HA in terms of anthropometric data or on proteins expression. Following the intervention, HG showed an average drop in core body temperature of 0.3° C post-exercise, a hallmark of acclimation to heat. Post intervention, no significant increase in HIF-1α, Hsp72 or EpoR levels was observed in the NG. In contrast, , a significant increase in resting HIF-1α, Hsp72 and EpoR expression (average upregulation of 111%, 29% and 13% respectively) was observed in the HG.

HIF-1α targeted pathways are activated by HA in animal studies, and contribute to various tissue protection. HA in human subjects also involves an upregulation of HIF-1α, Hsp72 and EpoR potentially implicating these proteins in the protective pathways associated with HA. Further work is required to investigate these proteins and their protective nature in human tissue.

THE EFFECT OF MENSTRUAL CYCLE ON CARDIOVASCULAR AND SUBJECTIVE RESPONSES DURING PROLONGED SUB-MAXIMAL EXERCISE IN THE HEAT.

ISHIJIMA, T., HASHIMOTO, H., SATOU, K., KANOSUE, K., MURAOKA, I., SUZUKI, K., HIGUCHI, M.

WASEDA UNIVERSITY

Purpose: Women before menopausal are exposed physiological and psychological changes by hormonal variation during menstrual phase. Although only a few studies with hormonal verification have investigated cardiovascular and subjective responses to submaximal exercise in the heat, no changes were found over the menstrual cycle for these responses. As the cause of "no changes", it should be pointed out the problem of the exercise protocol (exercise intensity and duration). This study was examined the effect of menstrual cycle on cardiovascular and subjective responses during prolonged submaximal exercise for young adults women in heat.

Methods: Six healthy young women with regular menstrual cycle (age=21.7±0.7yr, VO2max=35.7±3.4ml/kg/min) completed two trial consisting of 90 minutes cycling exercise at 50%VO2max in the heat (temperature; 30℃, humidity; 50%) during the folicular phase (FP; day 2-7) and luteal phase (LP; day 18-24) of their menstrual cycles in a randomized, crossover design. Before and after exercise, blood sample was taken to measure sex hormone concentrations. Subjects did not ingest any fluid during cycling exercise. During cycling exercise, VE, VO2, VCO2, respiratory rate (RR), respiratory exchange ratio (RER), heart rate (HR), body core temperature (BCT), RPE-Overall (RPE-O), RPE-Cardiovascular (RPE-C) and RPE-Legs (RPE-L), blood glucose, blood lactate were measured every 15 minutes.

Results: Serum estradiol and progesterone concentration were higher during LP compared FP (estradiol; 162±45 vs. 74±25pg/ml, P<0.05, respectively, progesterone; 7.9±1.9 vs. 1.2±0.5pg/ml, P<0.05, respectively). During cycling exercise in the heat, body weight loss at LP trial was higher than FP trial (1.13±0.16 vs. 0.93±0.13kg, P<0.05, respectively). During cycling exercise, VO2, HR, RR and BCT were significantly increased at both FP and LP trials. Although RER during LP trial was higher than FP during cycling exercise, any other cardiovascular parameters did not differ between FP and LP trial. All RPEs were significantly increased during cycling exercise at both trials. RPE-Overall and RPE-Legs during LP trial were higher than FP trial all over the cycling exercise (RPE-Overall; 14.2±1.2 vs 13.2±1.5, P<0.05, RPE-Legs; 14.8±1.1 vs 13.7±1.4, P<0.05, respectively, at the end of exercise).

Discussion; This study suggested that a physiological and psychological strains increased for the luteal phase during prolonged submaximal exercise in heat condition. VO2, VE, HR, BCT and RPE-Cardiovascular did not change over menstrual cycle. These results support most previous studies that cardiovascular responses during prolonged exercise in the heat were not changed over menstrual cycle. The higher RPE-Overall and RPE-Legs found for LP trial accompanied by a higher RER. Furthermore, these results may lead to a decrease in prolonged exercise performance in the heat.

NO CUMULATIVE EFFECT OF HOT AND HYPOXIC ENVIRONMENT ON THERMAL, CARDIOVASCULAR OR METABOLIC STRAINS DURING EXERCISE

GIRARD, O., RACINAIS, S.

ASPETAR - QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL

Introduction: Exercise in either hot or hypoxic conditions poses a severe challenge to multiple regulatory systems. However, the cumulative effect of these environmental stressors on exercise performance and underpinning limiting factors is still unknown. This study aimed to determine whether performance limitation when exercising in both a hot and hypoxic environment is associated with different thermal, cardiovascular and metabolic strains and perception of effort when compared to each individual environment condition.

Methods: 11 recreational athletes cycled to exhaustion at an intensity corresponding to 66% of their VO2max in four different conditions [Neutral/Sea level (CON), Hot/Sea level (HOT), Neutral/Hypoxia (HYP) and Hot/Hypoxia (H+H)]. Neutral and hot conditions were 22°C/30%rH and 35°C/40%rH, respectively; Hypoxia corresponded to a simulated altitude of 2500 m. The following parameters were recorded at exhaustion: core (Tcore, ingestible pill) and skin (Tskin, adhesive patch on the calf) temperatures, heart rate (HR), percent arterial oxygen saturation (SpO2), rating of perceived exertion (RPE, Borg scale) and blood lactate concentration ([La], fingertip). Data were compared by a two-way ANOVA (Temperature x Altitude) for repeated measures.

Results/Discussion: As expected, time to exhaustion was reduced (P < 0.05) in HOT (39 min 33 s ±20 min 59 s) or HYP (37 min 44 s ±14 min 39 s) when compared to CON (61 min 17 s ±27 min 48 s). H+H further decreased (P < 0.05) performance (26 min 32 s ±9 min 0 s), suggesting a parallel and cumulative effect of these two stressors on performance.

Hot conditions increased significantly HR (+9 ±5 bpm) and Tskin (+5 ±1°C) independently of the simulated altitude (both P < 0.001), whereas altitude exposure reduced SpO2 independently of the environmental temperature (96 ±1 vs. 88 ±4% in sea level and hypoxic conditions, P < 0.001). [La] values failed to be significantly different within conditions (5.6 ±3.4, 8.7 ±2.6, 7.9 ±6.2 and 10.0 ±5.4 mmol.L-1 in CON, HYP, HOT and H+H, respectively). There was no significant interaction effect between temperature and altitude on HR, Tskin, SpO2 and [La].

However, our data displayed a significant (P = 0.011) interaction effect on time to exhaustion. This interaction was due to a slightly reduced effect of either a hot (-34.6 ±14.8% from CON to HOT vs. -25.6 ±19.9% from HYP to H+H) or an altitude (-35.7 ±14.5% from CON to HYP vs. -26.0 ±19.7% from HOT to H+H) exposure when the other stressor is already present. That suggests that some limiting factors for performance are common to both a hot and hypoxic environment. In line with this, subjects stopped exercising at equivalent Tcore (38.5 ±0.6, 38.2 ±0.6, 38.4 ±0.7 and 38.4 ±0.5°C) and RPE (18.7 ±1.7, 19.3 ±1.0, 19.2 ±1.3 and 19.3 ±0.9) in CON, HYP, HOT and H+H.

Conclusion

There is no cumulative effect of combining hot and hypoxic environment on cardiovascular, metabolic or perceived strains despite exercise performance being reduced.

HYPERTHERMIA INDUCES OXIDATIVE STRESS IN RESTING BUT NOT IN EXERCISING HUMANS

LAITANO, O., KALSI, K.K., POOK, M., TRANGMAR, S., OLIVEIRA, A.R., GONZÁLEZ-ALONSO, J.

BRUNEL UNIVERSITY, UK. UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL, BRAZIL.

Hyperthermia imposes a severe stress to multiple regulatory systems including the redox system which is important for maintaining cellular homeostasis in resting and exercising humans. Glutathione (GSH) protects cells against oxidation by providing a substrate for glutathione peroxidase. GSH removes hydrogen ions and organic peroxides resulting in the formation of oxidized glutathione (GSSG). Therefore, the GSH/GSSG ratio is a sensitive marker of oxidative stress. The aim of this study was to determine the effects of isolated hyperthermia on oxidative stress in resting and exercising humans. We hypothesized that isolated hyperthermia would increase oxidative stress as indicated by alterations in GSH metabolism reflecting a decrease in GSH/GSSG ratio ([GSH-GSSG]/[GSSG]). Eight healthy males took part in this study. Participants wore a water-perfused suit and performed a 6 min one-legged knee extensor exercise at 50% of their predetermined maximal peak power output both under control and hyperthermic conditions while maintaining euhydration by ingesting1.3 ± 0.3 L of water. Following the control trial and a 15 min resting period, hot water (~ 48°C) was perfused through the suit for ~75 min in order to increase rectal temperature from 37.0 ± 0.3 to 38.3 ± 0.4 °C and skin temperature from 33.1 ± 1.6 to 38.7 ± 0.9°C. Blood samples were withdrawn before and at the fifth minute during both exercise bouts for determination of GSH and GSSG concentration by spectrophotometry assay. At rest, hyperthermia did not alter GSH (620 ± 289 vs 693 ± 379 µM, p= 0.093), but increased GSSG (6 ± 4 vs 12 ± 8 µM, p = 0.012), thereby leading to a significant reduction in the GSH/GSSG ratio (127 ± 84 vs 64 ± 51 µM, p= 0.017). This indicates an independent hyperthermia-induced oxidative stress. Conversely, during exercise hyperthermia increased both GSH (569 ± 313 vs 821 ± 440 µM, p = 0.036) and GSSG (6 ± 3 vs 16 ± 17 µM, p = 0.012). Consequently, GSH/GSSG ratio did not change (108 ± 71 vs 88 ± 67, p = 0.208). In conclusion, these results in humans demonstrate that hyperthermia induces oxidative stress at rest but not during exercise because a parallel increase in antioxidant defense offsets hyperthermia-induced oxidative stress.

EFFECT OF WORKING IN HOT ENVIRONMENT ON HEALTH AND PHYSICAL ABILITIES: AN OIL AND GAS INDUSTRY STUDY

RACINAIS, S., GIRARD, O., WALSH, A., KNEZ, W., GAOUA, N., GRANTHAM, J.

ASPETAR

Purpose: To investigate the alterations in physical work capacity occurring in the summer of a Middle Eastern country (Qatar – outside temperature between 40 and 50°C).

Methods: A group of 40 workers (oil and gas industry) with no previous experience of working in a Qatari summer volunteered to participate in a one-year follow-up project.

- Blood pressure and arterial oxygen saturation were obtained during the pre-experimental screening (April, before their first summer) as well as before (6 a.m.) and after (4 p.m.) work in the summer (August) and the following winter (January). Handgrip force was measured at the same time.
- Normalised physical activity (tri-axial accelerometer) and core temperature (ingestible pill) were recorded during the same working day.

Results: Blood pressure recorded before work decreased (P < 0.001) from April to August (from 136 ±13 and 84 ±11 to 125 ±11 and 77 ±9 mmHg for systolic and diastolic, respectively) but returned (P < 0.05) close to baseline values in January (130 ±16 and 80 ±11). Oxygen saturation decreased also (P < 0.01) from pre-screening (98.5 ±1%) to the summer (98.0 ±1%) and increased (P < 0.01) the following winter (98.5 ±1%). Both blood pressure and oxygen saturation were reduced (P ≤ 0.05) following the day of work but without interaction with the period of the year. Maximal handgrip force was significantly lower (P < 0.005) in August (38 ±7 kg) than in January (40 ±8 kg) independently of time-of-day.

Data at work. The normalised physical activity (acceleration) during the working hours was significantly (P < 0.02) lower in the summer (0.10 ±0.04 g) as compared to the winter (0.11 ±0.03 g). Average core temperature during work was significantly (P < 0.005) higher in August (37.4 ±0.2°C) than in January (37.2 ±0.2°C). However, no workers became hyperthermic as the highest observed value during the continuous recording was 38.3°C.

Discussion: The Company in which this survey was performed applies safety rules based on heat index (HI). The work/rest period (minutes) were reduced to 30/10 for a HI of 39-49, 20/10 for a HI of 50-53, and work stopped for a HI > 54. The summer data presented here were obtained on days with the highest HI (up to 53). Our data showed a reduced activity during the summer as a consequence of both these safety rules and the self-pacing of the worker. However, despite this reduced activity, central temperatures were higher in the summer month and workers presented with symptoms consistent with chronic fatigue (reduced blood pressure and saturation) associated with reduced maximal voluntary strength capacity.

Conclusion: None of these alterations were dependent of being tested before or after work suggesting that there were not linked to acute fatigue due to the day of work but rather to the presence of chronic alterations persisting during the summer months.

DOES PRECOOLING IMPROVE 1500 M SWIMMING PERFORMANCE?

KOCJAN, N., BOGERD, C.P., ALLENSPACH, P., PERRET, C., ROSSI, R.M.

EMPA, SWISS FEDERAL LABORATORIES FOR MATERIALS TESTING AND RESEARCH

Introduction: The literature suggests that precooling can increase exercise performance in a warm ambient. In particular, this is true for cycling and running performance (1, 2). However, it is unclear how precooling affects swimming performance. The present study aimed to investigate the effect of precooling on 1500 m swimming performance.

Methods: Eight subjects, 4 female and 4 male triathletes, participated in the study. Their average ± SD age was 29 ± 6 yr., height 173 ± 11 cm, weight 69.3 ± 12.1 kg and VO2peak 60.2 ± 6.3 ml•min-1•kg-1. Control (CON) and precooling (COOL) trials were performed on the same time of a day, at least one week apart. Both trials consisted out of: i)10 min warm-up at 40% of subject's VO2peak on a cycle-ergometer, followed by ii) 1500 m swimming at competition speed in water with the temperature of 27.6 ± 0.1 °C. In addition, during COOL trial subjects wore an ice vest (Arctic Heat, Burleigh Heads, QLD, Australia) 35 min preceding the warm-up and during the warm-up. During the trials, gastrointestinal temperature (Tc) and skin temperature on four body locations (Tsk) were continually registered. In addition, the subjects were asked to rate their thermal perception (TP) prior the warm-up and post swimming. Finally, the time for swimming 1500 m was noted.

Results: The effect of precooling was reflected in a significant 0.17 ± 0.18 °C decrease (p=0.045) in Tc and a 0.79 ± 0.33 °C decrease in Tsk (p=0.001). Lower Tc, observed for COOL trial, persisted till the end of swimming. In particular, Tc at the end of swimming was 37.89 ± 0.34 °C in COOL and 38.31 ± 0.34 °C in CON (p=0.049). In contrast, Tsk was not significantly different at the end of swimming among the trials. Prior to swimming, subjects rated TP in CON and COOL as slightly warm (1 ± 1) and cool (-2 ± 1; p=0.015), respectively. Likewise, at the end of swimming, subjects rated TP in CON trial as hot (3 ± 1), while in COOL trial as warm (2 ± 1; p=0.021). The swimming performance was with 22:29 ± 2:00 min significantly shorter in COOL trial compared to 23:04 ± 2:02 min observed for CON trial (p=0.014).

Conclusion

The observed results suggest that precooling with an ice vest, prior and during the warm-up significantly decreases Tc. Since lower Tc persisted through swimming it is suggested that this effect enables subjects to improve swimming performance.

THE EFFECT OF WORKING IN A HOT ENVIRONMENT ON MARKERS OF THE IMMUNE RESPONSE: AN OIL AND GAS INDUSTRY STUDY

KNEZ, W.L., RACINAIS, S., GIRARD, O., WALSH, A., GAOUA, N., GRANTHAM, J.

ASPETAR, QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL

Introduction: Physical activity in a high ambient temperature in comparison to neutral conditions has been demonstrated to impact on a number of immune markers. However, recent research shows little support for the previously held contention that physical activity in a hot environment further compromises the immune system in comparison to a neutral environment. However, due to ethical restrictions in laboratory-based research, investigations are limited to acute exposures of extreme heat. Indeed, some occupations involving fire fighters, soldiers and miners are required to live and/or work in extreme conditions. Subsequently, this study sought to determine the chronic effect of living and working in an extremely hit environment on immune system markers.

Method: The present study examined 30 apparently healthy (125/77 ± 11/9 mmHg systolic and diastolic blood pressure) male participants in hot (August; 410C) and neutral (January; 220C) conditions. Throughout the day, changes in core temperature were assessed by ingestible pills. In addition, blood was sampled from the antecubital vein before (5:30am to 7:00am) and after (3:30 to 5:00pm) their working day to assess changes in immune markers. A two-way repeated measures ANOVA was used to determine significant main effects and interactions.

Results: Mean core temperature was significantly ($p<0.01$) higher in August than in January (37.4±0.2 0C vs. 37.2±0.20C). There was a significant main effect of time-of-year ($p<0.05$ & $p<0.001$) for monocytes (7.1%) and lymphocytes (13.0%) with higher values obtained in August compared to January. A significant time-of-day effect ($p<0.001$) was observed from pre- to post-work in monocytes (16.1%), lymphocytes (26.3%) and neutrophils (7.0%). There was no significant time–of-year or time-of-day effects in interleukin-6, C-reactive protein or tumour necrosis factor. Furthermore, no significant interactions were identified.

Discussion: Despite significant increases in mean blood markers of immune function, the resultant values remained within a healthy reference range. Indeed, this result is not unexpected given the significant but modest changes observed in core body temperature. For safety reasons, the company involved in this study allowed their employees greater rest periods during times of extreme heat, which appeared to have a positive impact on the overall heat stress the employees experienced.

Conclusion: The present study showed that working in extremely hot field-based environment does significantly raise core body temperature in comparison to a neutral condition. However, due to the safety procedures put in place by the company, this increase was still within a normal range and subsequently the impact on the immune system whilst significant, values were still within a healthy reference range.

THE RELATIONSHIP BETWEEN FINGER SKIN TEMPERATURE AND THERMAL SENSATION DURING COLD WATER IMMERSION

TAIMURA, A., MATSUNAMI, M., NAKAGAICHI, M., SUGAWARA, M.

1. NAGASAKI UNIVERSITY (NAGASAKI, JAPAN), 2. BEPPU MIZOBE GAKUEN COLLEGE (BEPPU, JAPAN)

Introduction: We reported that mean finger skin temperature during ice water immersion and the coefficient of variation obtained from its standard deviation were useful indicators of cold-induced vasodilation (CIVD) response patterns and for evaluating local resistance to cold stress in different groups (Taimura et al., 2007, 2008). The purpose of this study was to analyze the relationship between finger skin temperature and thermal sensation during fingertip immersion in cold water.

Methods

Subjects were 17 male and 13 female college students who consented to participate in the present study. Subjects were not permitted to consume alcohol on the day before the test, engage in exercise on the day of the test, or eat during the 2 hours prior to the start of the test. After 60 min resting state in a controlled environment (room temperature, 27°C; relative humidity, 50%), a thermistor thermometer was placed on the middle finger. The middle finger was immersed in cold water (5.0°C), and finger skin temperature and thermal sensation were measured for 30 min. From the skin temperature and thermal sensation during cold water immersion, the CIVD and thermal sensation parameters were calculated.

Results: Subjects were divided into two groups those who had a rise in temperature before thermal sensation of the first rise (n=16, temperature first group (T)) and those who had a rise in thermal sensation before temperature of the first rise (n=14, sensation first group (S)). Mean skin temperature (MST), temperature of the first rise (TFR), time of temperature of the first rise (TTR), and amplitude of temperature and thermal sensation (AT) in the T-group and S-group were 9.92±1.91°C, 10.64±1.88°C, 7.27±1.67°C, 7.93±1.79°C, 5.79±1.56 min, 5.46±0.79 min, 5.36±2.12°C, and 5.33±2.92°C, respectively. Mean thermal sensation (MSS), thermal sensation of the first rise (SFR), time of thermal sensation of the first rise (TSR), and amplitude of thermal sensation (AS) in the T-group and S-group were 1.73±0.69, 2.49±0.58, 1.22±1.06, 0.83±0.56, 8.33±4.32 min, 3.82±0.86 min, 2.59±1.22, and 3.44±1.50, respectively. There were significant differences in TSR and MSS between the two groups. The mean values of AS/AT in the S-group (2.49±0.58) were significantly higher than that of the T-group (1.73±0.69). The time difference of TTR and TSR was smaller in the S-group.

Conclusion: The sensitivity of the thermal sensation was higher in the S-group during finger immersion in cold water. These findings suggest that the resistance to cold stress of the S-group is higher than that of the T-group, and this difference is related with complaints of unusual coldness. In future studies, we plan to investigate the relationships among factors such as sex, age, and level of exercise and training.

THE EFFECT OF CRUSHED ICE INGESTION ON 40 KM CYCLING TIME-TRIAL PERFORMANCE.

PEELING, P., IHSAN, M., LANDERS, G.

THE UNIVERSITY OF WESTERN AUSTRALIA

Pre-cooling is a temperature regulation strategy whereby core temperature (Tc) is lowered prior to exercise, and has been consistently shown to improve endurance capacity and athletic performance. However, pre-cooling protocols such as water immersion and cold air exposure are time consuming, logistically demanding and in some instances may result in adverse thermal responses, making these conventional methods impractical as a pre-event strategy.

Endogenous cooling methods (i.e. fluid ingestion) have been shown to attenuate the rise in Tc during exercise. Despite the positive effects of fluid ingestion on Tc responses to exercise, the effect of fluid temperature has been less established. As such, it was the purpose of this study to examine the effect of crushed ice ingestion as a pre-cooling method on body temperature response and cycling time-trial performance.

Seven trained male athletes completed a familiarisation, and two experimental 40 km cycling time trials (CTT) on a wind-braked cycle ergometer in a climate controlled chamber, set to 30oC and 75% relative humidity. The two experimental CTT included one trial preceded by a 30 min period of thermoneutral (26.8 ± 1.3°C) water consumption (CON), and the other by a 30 min period of pre-cooling via crushed ice (1.4 ± 1.1°C) consumption (ICE). The fluid volumes in each trial amounted to 6.8 g•kg-1 body mass. The order of trial completion was randomised, counterbalanced and completed within 14 days following the initial session. Each 40 km CTT required athletes to complete 1200 kJ of work in the fastest time possible. During the CTT, skin temperature (Tsk), Tc, cycling performance time, power output, heart rate (HR), blood lactate (BLa), and ratings of perceived exertion (RPE) / thermal sensation (RPTS) were measured at set intervals of work.

Pre-cooling lowered the Tc after ICE (36.74 ± 0.67°C) significantly more than CON (37.27 ± 0.24°C), ($p>0.05$). This difference remained evident until 200 kJ of work was completed on the bike (ICE: 37.43 ± 0.42°C, CON: 37.64 ± 0.21°C). The CTT completion time was 6.5% faster in ICE when compared to CON ($p<0.05$). No significant differences existed between conditions at any time point of the CTT for Tsk,, HR or RPE ($p>0.05$). The RPTS was significantly higher in CON at 200 kJ of cycling compared to ICE ($p<0.05$).

Ice ingestion was effective in lowering Tc and improved subsequent 40 km cycling performance in a hot / humid environment. A reduced thermal strain was evident in ICE compared to CON at the start of the CTT. Interestingly, split time data indicated that the latter parts of the CTT (900-1100 kJ) were significantly faster in ICE compared to CON despite no significant differences in HR, BLa, Tc, RPE and RPTS. The lower thermal strain evident in ICE compared to CON at the start of the CTT may have provided a greater heat storage capacity and muscle energy reserve that was used towards the end of the CTT, resulting in an enhanced time trial performance.

LOWER HEAD TEMPERATURES DID NOT AFFECT SELF-PACED RUNNING VELOCITY IN CHILDREN WEARING A CAP UNDER THE SUN

PRADO, L.S., FEREIRA JR, J.B., MARTINI, A.R., BORBA, D.A., COELHO, L.G.M., PINTO, J.U., OLIVEIRA, B.M.S., RODRIGUES, L.O.C.

FEDERAL UNIVERSITY OF MINAS GERAIS

Objective: Aim of the present study was to test the hypothesis that the use of a cap represents a barrier against sun radiation which would allow a lower heat accumulation during a 6 km self-paced run in children and, therefore, a higher running speed. Methods: Nineteen healthy boys and girls inhabitants of a tropical region (19,9° S of latitude and 43,9° W of longitude) (10,3 ± 0,7 and 10,2 ± 1,0 years old; 148 ± 6 and 145 ± 8 cm body height; 39,1 ± 6,1 and 34,8 ± 4,1 kg body mass; 1,3 ± 0,1 and 1,2 ± 0,1 m2 BSA, 17,8 ± 2,1 and 16,6 ± 1,8 BMI and VO2peak of 45,9 ± 1,9 and 42,5 ± 2,4 mL.kg-1.min-1 for boys and girls, respectively), took part in 4 experimental situations: 2 initial exercise sessions for familiarization and 2 self-paced 6 km runs with (CAP) and without (NOCAP) a cap (an all white polyester "Nike Dry-fit" cap, 7 cm brim length). CAP and NOCAP had their order randomized and balanced, were carried out in an external environment under sun radiation and at least 3-7 days apart. Each 6 km run was divided in 4 x 1,5 km exercise bouts with 3 minutes rest intervals. Subjects received information regarding distance yet to run every 100 m. Environmental variables were measured every 10 minutes during exercise protocols and physiological variables immediately before and after each run, and during the 3 minute rest intervals. Results: WBGT temperature, environment luminosity, running velocity (Vrun) and average skin temperature diminished during CAP and NOCAP, but were not significantly different. A higher Vrun was observed for the boys in both CAP and NOCAP, but no significant differences were observed between CAP and NOCAP for boys and girls, and also for all subjects when genders were treated together. Vrun decreased during the exercise bouts in all exercise situations. Mean luminosity at the forefront was reduced in 218 Lux (93%) and

mean head temperature was 1,7 ºC lower in CAP for boys and girls together. Mean heart frequency (HF) during rest periods was lower than during the exercise bouts, but was not statistically different between CAP and NOCAP. RPE and perception of thermal comfort (PTC) were not altered due to cap use, but increased during the exercise bouts in CAP and NOCAP. A positive correlation was observed between Vrun and VO2peak (r=0,64; p=0,002; r2=0,4). Conclusions: Cap use led to a decrease in mean head temperature. However, it was not sufficient to alter Vrun. Vrun decreases during all exercise bouts may have occurred due the action of a neural mechanism for homeostasis protection.

EFFECTS OF EARLY-EVENING EXERCISE ON ACYLATED GHRELIN, LEPTIN AND PERCEIVED HUNGER MEASURED DURING A SUBSEQUENT SIMULATED NIGHT-SHIFT

MORRIS, C., FULLICK, F., GREGSON, W., CLARKE, N., DORAN, D., MACLAREN, D., ATKINSON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: Shift-work, and particularly night-work, is common in Europe and is an independent risk factor for obesity (Atkinson et al., 2008). Shift-workers tend to 'graze' on high-fat foods during a night-shift and postprandial thermogenesis is lower at night, which, in combination, may compromise energy balance (Romon et al., 1993). Thus, a reduction in energy intake, by suppressing hunger could benefit the night-worker. Exercise in the late morning suppresses perceived hunger and associated regulators such as ghrelin (Broom et al., 2007) and leptin, for many hours. Although it is known that these hormones show circadian variation when measured at rest, no examination of the responses of these variables to exercise over a subsequent period of night-work has been attempted. We hypothesise that the responses of perceived hunger, ghrelin and leptin are different when awake and eating at night compared with previous studies undertaken during the day.

Methods: Six healthy males (age: 30±8 y, body mass: 74.1±6 kg, height: 178±8 cm) completed two trials (exercise and control) in a random order. In the exercise trial, participants fasted from 10:00 h, consumed a test meal at 18:00 h and then cycled at 50% peak oxygen uptake between 19:00-20:00 h. Participants then remained awake until 05:00 h, consuming two identical meals at 22:00 and 02:00 h. Participants rested between 19:00 and 20:00 h in the control trial. During each trial, venous blood samples were drawn at 1-h intervals between 20:00-05:00 h for the determination of acylated ghrelin, leptin, insulin and glucose concentrations. Perceived hunger was also recorded at these times. Data were subtracted from baseline and analysed with two factor (trial x time) linear mixed models. Data are described as mean±SD.

Results: Perceived hunger increased by 0.3±2.0 units throughout the night-work after exercise compared with a reduction of 1.2±2.3 units in the control trial ($P<0.0005$). Acylated ghrelin increased by 25.7±40.1 pg/ml during the night after exercise compared with 11.6±51.5 pg/ml in control ($P=0.004$). Insulin decreased by 37.8±136.8 pg/ml after exercise compared with a decrease of 95.0±116.2 pg/ml in control ($P=0.008$). Changes in glucose and leptin concentrations during the night-shift were unaffected by prior exercise ($P>0.05$).

Conclusions: We report, for the first time, that evening exercise increases perceived hunger and acylated ghrelin concentration during a subsequent night-shift. These data are in contrast to those from studies on diurnally-active individuals in which an exercise-mediated suppression of acylated ghrelin was observed (Broom et al., 2007). Therefore, the effects of exercise on appetite and its regulators appear different in the nocturnal period, which may help to explain the higher long-term risk of obesity in shift-workers.

SHORT-TERM MEMORY IN POSTMENOPAUSE. WEIGHT OF DIFFERENT PREDICTORS VARIABLES

DI BLASIO, A., DI DONATO, F., DI RENZO, D., GALLINA, S., NAPOLITANO, G., VALENTINI, P., RIPARI, P.

G. D'ANNUNZIO UNIVERSITY, CHIETI

Introduction: Literature widely shows the memory decline age-related, even if, on the other side, it documented the protective role of physical exercise, diet, and both hormonal and anthropometric pattern on memory. Aerobic fitness protects and enhances memory through hippocampal neurogenesis related to the increase of cerebral blood flow exercise-dependent. The dietary habitudes play a fundamental on the memory functions through its quantitative and qualitative characteristics that can lead to diabetes, hypertension, stroke and excessive oxidative stress altering brain structure and functions. Both estrogens and leptin patterns have positive functional implications in memory processes, as excessive stress hormones have a negative role. So that, menopause-related hormonal modifications becomes important in memory decline. Because the aromatasic activity of adipose tissue may partially replace estrogens deficit after menopause, in this period, body fat (FM%) has been shown positively related to memory. The aim of this study was to investigate the influence of dietary, anthropometric, and physiological parameters on short-term memory (STM) in postmenopause.

Methods

25 postmenopausal healthy sedentary women (53.46±3.32 yrs) were recruited by general physicians attesting no metabolic, cerebrovascular and cognitive diseases. Body composition was assessed by multi-frequency electrical bioimpedance (Ds Medica, Italy). Qualitative and quantitative characteristics of daily meals were estimated by a dietician from three-day dietary records, covering two weekdays and one weekend day, using WinFood-due software (Medimatica, Italy). STM was measured though Digit Span Test, composed by both forward and backward numbers repetition, included in Attenzione e Concentrazione software (Erikson, Italy). VO2max was estimated (VO2maxest) by Rockport Fitness Walking Test after the STM test.

Results: Nobody had results of STM test below the reference values. Participants had 35.01±6.92 of FM% and a VO2maxest comprised between 26.90 and 40 ml/kg/min. A multiple regression model (p=0.008) was performed taking Digit Span Test score as dependent variable, while VO2maxest, FM%, diastolic blood pressure, intake of percentage lipids and carbohydrates, folic acid, vitamin A, D, B complex, and E were predictors variables. Only vitamin D intake (coeff. est.=0.732, t=4.950, p<0.001) was significant as predictor of STM. The same was obtained taking only backward numbers repetition result as dependent variables.

Discussion

Vitamin D intake seems to be the best predictor of STM in an integrated regression model taking into account several influencing variables. Literature suggest that the neurocognitive benefits of vitamin D seems to be related to the increase of acetylcholine concentration, neurotrophin synthesis and antioxidant capacity in the brain. So, to reach the recommended daily intake of vitamin D could lead to have both cognitive and skeletal health in postmenopause.

IS THERE A MINIMUM REQUIREMENT FOR FAT INTAKE IN ATHLETIC NUTRITION?

TOMTEN, S.E., HØSTMARK, A.T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: In contrast to extensive research on the significance of dietary carbohydrates and proteins for performance and health, the possible existence of a minimum requirement of fat in athletic nutrition has received little attention.

The intake of important fat soluble vitamins may be limited when the nutritional content of fat is reduced, and increasing evidence of low dietary intake of vitamin E in modern Western societies has been presented within the general population. population (Maras et al., 2004). Additionally, a low fat diet is suspected to reduce the absorption and bioavailability of vitamin E (Wolf, 2007), making dietary estimates an uncertain predictor for vitamin E status.

Among the components of vitamin E in blood, alpha-tocopherol is the most potent antioxidant, protecting cell membranes from oxidative damage, and as athletic anemia has been frequently discussed, it was of interest to investigate if a low vitamin E bioavailability in athletes on a low fat diet could possibly cause damage to red blood cells.

Subjects and Methods: To investigate this aspect two groups of sub-elite athletes participated. One group had regular menstrual function R and the other was irregular (IR). The two groups had similar height, weight and athletic success.

While intakes of protein and carbohydrates were similar and within normal range in the two groups, the daily intake of fat was significantly lower in the IR group (61± 6g; 1.1±0.1g/kg), than in the R group(98±12g; 1.7±0.2 g/kg). In order to determine the resistance of red blood cells to haemolysis, 13 participants, exercised for 20 min at the anaerobic threshold (HF =171±2 in R and HF = 172±3 in IR).

Results: Normal serum levels of alpha-tocopherol was found in the R group (27.3±3.6 micromol/L), while the IR group had a very low content (15.7 ± 0.8 micromol/L).

In blood sampled after the exercise, osmotic fragility of red blood cells (%hemolysis) was found to be significantly negatively related to serum levels of alpha-tocopherol.

Conclusion: A low fat content in the food may indicate a reduced alpha-tocopherol levels in blood which seems to render the red blood cells more susceptible to haemolysis in connection with physical activity. This should be taken into account when nutritional guidelines are given.

PHYSICAL ACTIVITY AND ADHERENCE TO THE MEDITERRANEAN DIET INCREASES TOTAL ANTIOXIDANT CAPACITY: THE ATTICA STUDY

ARNAOUTIS, G., KAVOURAS, S., PANAGIOTAKOS, D., PITSAVOS, C., CHRYSOHOOU, C., SKOUMAS, Y., STEFANADIS, C.

HAROKOPIO UNIVERSITY

Introduction: The beneficial effects of the Mediterranean diet on human health are well documented. Simultaneously, physical activity has been evolved as a significant factor in the prevention of many cardiovascular and metabolic diseases as well as some kinds of cancer, while the determination of antioxidative capacity is a well established tool in medical diagnosis and treatment of such diseases. One of the most widely accepted index of whole body antioxidant ability is the total antioxidant capacity (TAC). Therefore, the aim of this study was to investigate the association of physical activity and the Mediterranean diet, on total antioxidant capacity.

Methods: A random sample of 1514 men and 1528 women was selected from all areas of Attica region (including 78% urban and 22% rural areas). Physical activity was assessed with a translated version of the validated "International Physical Activity Questionnaire" (iPAQ) categorizing the subjects to: inactive, minimally active and HEPA active (health enhancing physical activity; a high active category). Food consumption was evaluated through a validated FFQ. Adherence to the Mediterranean diet was assessed by the MedDietScore that incorporated the inherent characteristics of this diet.

Results: TAC was positively correlated with the degree of physical activity (p<0.05). TAC was also positively correlated with MedDietScore (r=0.24, p<0.001). Stratified analysis by diet status revealed that the most beneficial results were observed to highly active people (HEPA active) compared to inactive, who also followed the Mediterranean diet (19.7±7.4 μmol/L, p=0.03), after adjusting for various confounders.

Discussion: Both, intense physical activity and Mediterranean diet were positively correlated with increased total antioxidant capacity, with the most beneficial results observed among people that have both the highest level of physical activity and the greater adherence to

the Mediterranean diet. Therefore it is concluded, that the combination of increased and frequent exercise and the adoption of low fat dietary patterns, like the Mediterranean diet, enhances antioxidant defenses.

IRON STATUS IN YOUNG ELITE ATHLETES: INFLUENCE OF DIET, EXERCISE AND GENDER

KOEHLER, K., BRAUN, H., ACHTZEHN, S., PREDEL, H.G., MESTER, J., SCHAENZER, W.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Despite widespread research and education, iron still has to be considered as one of the most critical nutrients in public health as well as in exercise nutrition. The prevalence of iron depletion among athletes tends to be higher than in the general population. Additionally, there is sufficient evidence that suboptimal iron status may influence exercise capacity and/or sport performance.

Hence, the present study was designed to identify the influences of gender, diet and exercise on iron status across a wide range of sports and levels of competition in young elite athletes.

METHODS: Diet, exercise and haematological data from 177 junior elite athletes (100 f, 77 m; 16.3 +- 3.0 y, 64.8 +- 13.5 kg, 174.3 +- 10.9 cm) from 32 different sports were analyzed retrospectively. Diet and exercise data were collected during seven days using a standardized and validated record. Following the recording period, fasting blood samples were obtained from the athletes.

RESULTS: Among all athletes, approximately 40 % had reduced serum ferritin levels. About 4 % of the athletes were anaemic. Female athletes had significantly more abnormal haematological values and consumed significantly less dietary iron, cobalamin (both $p < 0.001$) and folic acid ($p < 0.01$).

Athletes with low ferritin levels indicative of iron depletion consumed significantly less meat and fish ($p < 0.01$) than athletes with regular levels. Female athletes with iron depletion had a significantly lower iron density in their diet (5.8 +- 0.9 vs. 6.5 +- 1.1 mg/1000 kcal, $p < 0.01$), which was not the case in male athletes. However, only in male athletes ferritin levels were significantly affected by practice duration and energy expenditure ($p < 0.05$).

DISCUSSION: There were a noticeable number of cases with low ferritin levels indicative of iron depletion among young elite athletes. Our results suggest that the interrelations between an athlete's iron status and his/her diet and exercise regimen is affected by the athlete's gender: in female athletes, iron depletion was more prevalent and serum ferritin levels were primarily affected by dietary iron density; in male athletes, energy expenditure and practice duration seemed to influence iron status strongly.

DEVELOPMENT AND VALIDATION OF A FOOD FREQUENCY QUESTIONNAIRE TO ASSESS SHORT TERM ANTIOXIDANT INTAKE

BRAAKHUIS, A.J., HOPKINS, W.G., LOWE, T.E., RUSH, E.C.

WAIKATO INSTITUTE OF TECHNOLOGY

A quantitative food-frequency questionnaire was developed to determine habitual antioxidant intake. Measures of semi-concurrent validity were obtained for 81 participants by comparing antioxidant intakes from the questionnaire with those from a 7-d food diary completed in the week following administration of the questionnaire. Measures of construct validity were obtained for 96 participants by comparing concentration of a biomarker of antioxidant capacity (ferric reducing ability of plasma) in a blood sample taken at the time of administration of the questionnaire with antioxidant intakes from the questionnaire. Validity between the food diary and antioxidant biomarker was obtained for 63 participants. The correlation between the diary and questionnaire energy-adjusted estimates of antioxidant intake was modest ($r = 0.37$; 90% confidence limits, ±0.14). The correlation between the questionnaire estimate and biomarker was also modest ($r = 0.33$; ±0.15), whereas the correlation between the diary estimate and biomarker was negligible ($r=-0.06$; ±0.15). The correlation between the food diary and questionnaire food groups were high for both cereals ($r = 0.55$; ±0.11) and coffee and tea ($r = 0.51$; ±0.15), moderate for fruit ($r = 0.31$, ±0.16) and vegetables ($r = 0.34$; ±0.16). Cereals contributed a major proportion (31.6%) of the total antioxidant intake. One-week test-retest reliability of the questionnaire's estimates of antioxidant intake in 20 participants was high ($r = 0.81$; ±0.16).

The food-frequency questionnaire is less labour intensive for participant and researcher than a diary and appears to be at least as trustworthy for estimating habitual antioxidant intake.

PILOTSTUDY: ROLE OF MOTIVATION IN ELITE AND NON-ELITE YOUTH BASKETBALL PLAYERS

TROMP, E.J.Y., ELFERINK-GEMSER, M.T., JONKER, L., TOERING, T.T., VISSCHER, C.

UNIVERSITY OF GRONINGEN

Personality characteristics could be a critical factor in distinguishing successful players from their less successful counterparts (Williams & Reilly, 2000). Motivation is claimed to be such a personality characteristic and is best predicted by two attributes, i.e., effort and self-efficacy (Hong & O'Neil, 2001). Effort is believed to be a crucial component to commit to the deliberate practice that is needed to reach successful performance (Ericsson, Krampe & Tesch-Römer, 1993). Self-efficacy refers to the beliefs about one's capability to execute actions in order to reach a certain goal (Bandura, 1997). Even though motivation plays a crucial role, it is still not fully understood whether motivation should be measured as a more general personality characteristic, or as a more domain-specific personality characteristic related to reaching (top) sport performance.

This study is a part of a larger study that will examine the role of motivation in a wider range of elite and non-elite youth indoor ball team sport athletes. To gain more insight in the role of motivation, it was decided to first examine possible differences in generalized effort and self-efficacy. The purpose of this pilot study is therefore to examine the role of motivation between elite (n=22, mean age ± SE: 15.13 ±

1.45 yrs) and non-elite youth male basketball players (n=18, mean age ± SE: 14.06 ± .998 yrs). Players were classified elite when they were playing in international or national youth competitions and were classified non-elite when they were competing at regional level. Motivation was assessed with a questionnaire pertaining questions about two aspects of motivation: generalized effort and self-efficacy. Multivariate analysis of covariance with performance level as factor (elite versus non-elite) and age as covariate was conducted. A significance level of .05 was adopted. The results revealed no significant differences between elite and non-elite players on either effort or self-efficacy ($p > .05$). However, there was a trend with elite players outscoring their non-elite counterparts with moderate effect sizes on both motivational attributes ($d = .42$ on effort and $d = .43$ on self-efficacy). The findings of our study showed that elite athletes did not score higher on either generalized effort or self-efficacy. Nevertheless, based on the medium effect sizes found, the results might mean that general motivation is partly needed to reach higher sport performance. Yet, it would be interesting to further examine whether larger differences can be found when motivation would be measured more sport specific.

TOWARDS AN UNDERSTANDING OF DEBRIEFING IN SPORT

MCARDLE, S.
DUBLIN CITY UNIVERSITY

Over the past twenty years, post performance evaluation has been increasingly utilized in sport to facilitate learning, to inform training and to improve performance (Hogg, 2002). Debriefing has been described as an extension of post performance evaluation in that in addition to learning and performance improvement, it incorporates the aim of facilitating mental and emotional recovery post competition (Hogg, 2002). Whereas post performance evaluation has received a significant amount of attention in the motor learning, behaviour and control literature, very little attention has been given to the process of debriefing in applied sport psychology (Hogg, 2002). The purpose of this study was to ascertain if athletes' and coaches' experience and understanding of debriefing aligned with the existing conceptualization of debriefing in sport (see Hogg, 2002). Factors thought to influence the debriefing process (e.g. timing of the debrief) were also investigated.

This study used a qualitative method of inquiry to explore the participants' subjective debriefing experiences. Seventeen participants, six coaches and eleven competitive athletes from both team and individual sports participated in semi-structured interviews. Athletes ranged in age from 18 to 29 years ($M=21.09$, $SD=3.30$). Employing inductive analysis, the results indicated that coaches' and athletes' understanding of debriefing was similar to Hogg's (2002) model of debriefing in sport in many respects. Both coaches and athletes perceived debriefing as an opportunity to exchange views on performance so that the athlete or athletes could learn from the experience. It was also generally believed that debriefing provided a focus for training and fostered motivation. However, no coach or athlete explicitly stated that they viewed debriefing as a means of facilitating mental and emotional post performance recovery.

Similar to empirical research in clinical psychology, the results indicated very little consensus as to "the ideal time" to conduct a post performance debrief. Athletes who participated in team sports were more likely to experience 'delayed' debriefing whereas those in individual sports were more likely to experience 'immediate' debriefing. Overall, the results suggest that athletes' and coaches' experience and understanding of the debriefing process was more closely aligned to models of debriefing in education versus the current conceptualization of debriefing in sport. Given the paucity of studies in the area of debriefing in sport, the current study provides a useful starting point for this line of research.

SUCCESSFUL ICE HOCKEY OFFICIATING: WHAT SKILLS ARE NECESSARY?

DORSCH, K., CHOMOS, A., RAAKMAN, E., SCHINKE, R.S., PASKEVICH, D.M., RIEMER, H.A.
UNIVERSITY OF REGINA, JUSTPLAY SPORT SERVICES, LAURENTIAN UNIVERSITY, AND UNIVERSITY OF CALGARY

Introduction: Self-efficacy is the degree to which an individual feels confident in their abilities to execute specific skills necessary for successful completion of their task (Bandura, 1997). In the context of sport, self-efficacy research has been conducted and applied mainly with athletes and coaches. There is, however, a group of individuals on the playing field that have, for the most part, been neglected. We recognize this group as sports officials. To be able to understand the antecedents and consequences of self-efficacy of sports officials, the first step is to determine what skills and abilities are necessary for successful officiating. The purpose of this research is to identify specific skills and abilities deemed essential by officials for successful officiating experiences in the sport of ice hockey.

Methods: Through collaboration with Justplay Sport Services, data were collected via a secure internet website. Participants were asked to complete an open-ended questionnaire. designed to identify those skills necessary for officiating.

Results: Responses from 121 ice hockey officials were obtained. Through content analysis, responses were coded as either technical skills (abilities that require the application of a specific technique) or as mental skills (abilities that involve the mind and various mental processes). Further analyses showed the predominant technical skills to include: knowledge of game/rules; communication skills; physical abilities/attributes; experience. The mental skills included: heightened awareness; decision-making processes; attitudinal skills; judgment skills; confidence; affective capabilities; passion; conflict management skills; mental preparation abilities.

Discussion: The identification of the skills ice hockey officials feel are crucial for successful performance is the first step in understanding the relationship between self-efficacy for ice hockey officiating and officials' performance, training, and retention. The information gathered by this research will be essential in the development of sound psychometric instruments assessing self-efficacy for ice hockey officiating.

DIFFERENTIAL COUNSELING FOR LEISURE SPORT AND EXERCISE - A CLUSTER-ANALYTICAL APPROACH

CONZELMANN, A., SUDECK, G., LEHNERT, K., AMACKER-MÜLLER, C.

UNIVERSITY OF BERN

Current reviews concerning the psychological benefits of physical exercise often conclude that the low to moderate effects can't be generalized. There is little knowledge about the causal mechanisms and additionally a lot of moderators have to be considered. Further research has to address the question, for which person could which kind of exercise lead to which psychological effects under which circumstances. Answers to this question can partly illuminate the affect-adherence-link, which is assumed to be of particular relevance for the maintenance of physical exercise.

Our study approach faces this question by analyzing the effects of individually matched exercise programs on psychological well-being and exercise adherence in a quasi-experimental design. We argue that an individually matched exercise program has to fit the individual needs and expectations to attain improvements of psychological well-being in the long run. If the exercise program succeeds in this regard, exercise adherence will be promoted as well.

The study design started with a matching process, which at first included a comprehensive assessment of n = 231 middle-aged adults. During a 90-minutes test session the participants were interviewed about their past and current physical exercises and sport activities. Furthermore, we used a computer-assisted assessment of various motives for leisure sports and we tested the participants' motor abilities. In a next step we conducted a cluster-analytical classification of the target group with respect to their motives for leisure sports. After that we developed target-group specific exercise programs and invited the participants to take part in two 13-week-intervention periods. The effectiveness of these individually matched programs was analyzed based on changes of psychological well-being and program attendance from the beginning to the end of the intervention periods. By comparison with a control group causal mechanisms were also examined.

In the paper, we present the results of the cluster-analytical classification of the target group in terms of nine typologies of motive profiles. Further these typologies will be compared with psychological and motor variables, which are known as important for the maintenance of regular exercise as well as for the designing of tailored exercise programs. Against this background we point out the five conceived intervention programs and we present results of the first intervention period in regards to effects on subjective well-being and related parameters.

STEROID HORMONES IN THE SALIVA OF ADOLESCENTS AFTER EXERCISE AND THEIR INFLUENCE ON COGNITION

BUDDE, H., VOELCKER-REHAGE, C., PIETRASSYK-KENDZIORRA, S.

SPORTSCIENCE HU-BERLIN

It is well known that physical activity increases serum steroid hormone (SH) levels such as Testosterone (T) (Maresh et al., 1988) and Cortisol (C) (Kirschbaum & Hellhammer, 1994). This is of particular interest since glucocorticoids (Lupien et al., 2005) and T (Hampson, 1995) in young adults have been shown to influence cognitive performance. Little is known, however, about the influence of different exercise intensities on cognition, the concentration of SH, or their interaction in adolescents. 60 high school students from the 9th grade were randomly assigned to two experimental (EG) and a control group (CG). Saliva collection took place after a normal school lesson (T1) and after a 12-minute resting control or exercise (T2) in a defined heart rate (HR) interval. Maximum HR (HR max) was measured one week prior to the investigation and used to ensure that the exercise levels were related to the individual HR max. (EG 1: 50-65%, n = 18; EG 2: 70-85% HR max, n = 20; CG: no intervention, n = 21). Saliva was analyzed for T and C. Cognitive performance was assessed using a working memory task (Letter Digit Span; LDS), which took place after T1 and T2. C and T levels of the high intensity group (EG 2) were significantly increased after 12 minutes of exercise training (T2). The repeated measure ANOVA revealed a significant group by test interaction, indicating an increase of C and T level for the EG 2 but not for EG 1 or CG. Results for the working memory task, showed a significant improvement due to exercise when groups were split into low and high performer at pre-test with a higher improvement of the low performers. In addition, there was a moderate correlation between T level and change in LDS-performance (r = -.40) in the EG 2, indicating a detrimental effect of increased T concentration on working memory. The results indicate that the concentration of the SHs C and T are intensity dependent, and that mainly low intensity exercise improves working memory in low performing adolescents. Only increased T, however, seems to be related to pre-to-post-test changes in working memory by having a detrimental effect on performance.

ARE THERE A CONNECTION BETWEEN SOCIAL REPRESENTATIONS OF AGGRESSION IN LIFE TODAY AND SPORT PRACTISE? THE CASE OF ATHLETIC AND NON-ATHLETIC YOUTHS

CHELLY, F., CHANTAL, Y., BRUNEL, P.

1. GROUPE DE RECHERCHE EN SOCIOLOGIE DU CENTRE OUEST EA 3815, UNIVERSITÉ DE LIMOGES, FRANCE, 2. DÉPARTEMENT STAPS, UNIVERSITÉ DE VERSAILLES SAINT QUENTIN EN YVELINES, FRANCE.

Introduction: Many authors suggest that our beliefs (SR) are related to our behaviour. They may influence the direction of aggressive comportments (Archer et al, 1997b). However, sport is a space of learning rules, duties and control of violence. Parisot, (1991) confirmed that the social skills developed in sport may be transferred in social life. The aims of our study are: on the one hand, we compared the SR of violence in sport and social life in athletic and non-athletic youths. On the second hand, we studied the link between daily social and sport representations of aggression among adolescent sport participants and non-participants.

Method

Participants:

265 adolescents (N = 123 athletics and N = 145 non-athletics) have answered on the Expagg and the social representation of violence in sport (QRVS) instruments.

Results: Only 23 questions in Expagg (9 expressive aggressions (EA)) and (16 instrumental aggressions (IA)) and 22 questions in QRVS (7 no violence (NVs), 6 verbal aggression (VAs) and 9 physical aggressions (PAs)) were retained after a Varimax Rotation exploratory factor.

Comparisons of scores

Compared to the non-participants in sport the athletic group scored less in total and IA of aggression (p<.001). Yet, there was no difference in EA. In SR of sport violence, the scores of PAs of the athletic group were weaker than those of the non-athletic adolescents (p<.001). There was no difference in VAs in the two groups. The athletic group scored more than the non-participants sport in NVs (p<.01).

Correlations in scores

There was a negative correlation between IA and PAs (r=-.20 p<.05) in the athletic group and a positive correlation in non-athletic youths (r=.35 p<.05). There was a negative correlation between VAs and EA in non-athletic youths (r=-.28 p<.05). But, no correlation was found in athletic youths.

Discussion: Our results of SR are similar of Bushman and al. (1999). Athletic adolescents are perhaps more self confident than non-athletic youths, that is why they have less aggressive beliefs than their fellows. The negative correlations in (IA and PAs) and (VAs and EA) confirmed that the connection between sport and daily life aggression is reversed. Athletic adolescents use sports like a space of violence to control social violence in every day life. They maintain a weak level of aggression compared to the non-athletic youths because they respect the rules and the duties in sport. We think that our research should be reinforced by the use of the aggression instrument to be more explicit in the study of the connection between SR and behaviour.

OP-HI01 History

THE POLITICAL USES OF SPORT IN THE UNITED STATES: HISTORICAL PATTERNS AND CONSEQUENCES

GEMS, G.

NORTH CENTRAL COLLEGE

This study will examine the political uses of sport in United States colonial and military occupational practices over the last century. Applying a Gramscian hegemonic framework it assesses the initiation and attempted cooptation of indigenous cultures through the introduction and inculcation of western sport forms. It also addresses the indigenous reactions to those practices in a variety of locations in Asia, Hawaii, and the Caribbean region.

The US has preached the doctrine and ideology of democracy, liberty, and equality; but actual practices have not always adhered to the rhetoric expounded. Dictators who upheld American commercial interests were supported and financed. US government initiatives to utilize sport as a means to sell American products were initiated as early as the 1920s.

There has been a close relationship between religion, race, and capitalism in the construction of an American empire. This study analyzes those relationships through the sporting practices of the American military, colonial governing bodies, and religious organizations to conclude that the historical patterns established more than a century ago are still prevalent in American Mideast policies today.

COLLECTIVE MEMORIES, POLITICAL MYTHS, TURNER IDEOLOGIES AND GERMAN IDENTITIES

PFISTER, G.

UNIVERSITY OF COPENHAGEN

Since the publication of Pierre Nora's monumental seven-volume "Les Lieux de Mémoire" (1992), research into "remembered places" is being carried out throughout the world with growing enthusiasm. The study of cultures of 'remembering' makes use of various research approaches and strategies. However, there is a consensus, that cultures reconstruct their pasts in communicative processes and incorporate those events into their collective memory, which they require for their current circumstances. Myths are a particular form of collective memory composed of narratives offering a selective and condensed account of events from the distant past. They appeal to the emotions, confer legitimacy on social organizations and structures, rationalize ideologies and norms, and lend meaning to a community's quest for self-reassurance (Flood 1996).

Myths of origin allude to persons, events and/or places who or which play a key role in the development of a community. Myth of origin are often combined with myths of persons, which focus on someone whose historical achievements are augmented, embellished and construed as being superhuman (Hein 2006). This is especially true of Friedrich Ludwig Jahn, the Turn Father in Germany, but also for the sport heroes in many countries.

The aim of this paper is, firstly, to examine the changing significance of Turnen festivals for the Turner identity and the creation of an "imagined community" and, secondly, to re-construct the place which the Turnen movement occupied (or saw itself as occupying) in German society. The contribution analyses the "places of memory" and myths (above all those surrounding the politics of gymnastics) created by the rituals and enactments that took place at Turnen festivals along with the declarations and messages that issued from them. This makes it possible to trace not only the image which the Turner had of themselves (and which was dependent on the prevailing political and socio-cultural circumstances) but also the nationalist discourses rooted in broad sections of the German populations in different historical epochs. The contribution focuses on the Turnen festivals held in Berlin in 1861 and in Leipzig in 1913. Sources are the Deutsche Turnzeitung and the commemorative publications of the Turnen festivals.

THE IMPACT OF ATHLETICISM ON THE EARLY EVOLUTION ON FOOTBALL

FRETLAND, F.

SOGN OG FJORDANE UNIVERSITY COLLEGE

Abstract

J. A. Mangan claim in his article in Soccer & Society in April 2008 that the impact of the educational ideology athleticism, was more important to the evolution of English Association Football than earlier presumed. He does not give any specific definition of the concept athleticism but in this article we can understand it as a game ethos which was taught the Victorian and Edwardian bourgeois youth. The aim was to "play the game" in the right way with moral values and fairness as guiding lines. The idea of athleticism had been an important part of the English educational institutions in the second part of 1900 Century. It had "both an ulterior and altruistic impact in the universities, public and grammar schools of the middle classes and ...on the teacher-training colleges and elementary schools of the working class" (Mangan 2008:174). In short, athleticism can be used as an analytic factor when it comes to explaining the spread and democratisation of modern football. The proletarian adopted athleticism when school teachers used it as a part of the teaching. Moral values as honesty, courage and fair play could be practised at the pitch but could also be transformed to other parts of life. Football could be used to teach good manners in social life for young people.

In this paper I'll try to explore and "translate" the use of athleticism into Norwegian terms. How important was the ideology of education for the spread and growth of football in Norway?

Matti Goksøyr and Finn Olstad used, in their book Fotball! (Goksøyr M, Olstad F, 2002), the concept of youth revolt to explain the development of football and its role in an early phase, as Rune Slagstad did it in his book on history of ideas of Norwegian sport (Slagstad 2008). Slagstad writes that Norwegian football developed most like a youth revolt where the young people their self made written and unwritten laws and administrated the football association (Slagstad 2008: 188). The youth was driven by a playful approach to football. PE-teachers and the School as a whole did not get the control they wished, claim Slagstad (ibid). That means the pedagogical ideas on character building (athleticism) were not important for the development of football in Norway in an early phase. I will question this, and try out if athleticism had some impact on the early evolution of football, maybe more impact than Goksøyr, Olstad and Slagstad are claiming. Overall we can ask if athleticism can be used as a factor to explain popularity for football in Norway.

- YOU MUST BE A "TRØNDER". SOCCER FANS CONSTRUCTING COMMUNITY ON WWW.RBK.NO AND WWW.KJERNEN.NO

KRØVEL, R.

OSLO UNIVERSITY COLLEGE

(Quote: Nils Arne Eggen to a talented African player on trial with Rosenborg).

Introduction: Groups or cultures have values that are largely shared by their members. But what happens to groups, community and values when global flows of people, capital, goods and ideas challenge existing boundaries? This paper will investigate the process of construction or re-constructing the imagined community of supporters and members of Rosenborg Ballklubb (RBK) and the fan club Kjernen.

RBK went through a period of profound change in the years after approximately 1999 (Svardal 2007). The club had been founded by players in a traditionally working class neighborhood of Trondheim. During the 1960s and 1970s, RBK, the most successful team in Trondheim, also became the dominating team in the region of Trøndelag. Under the leadership of Coach Nils Arne Eggen, the club went on to win 15 national championships after 1990. This meant that the club represented Norway in the Champions League in a period when incomes grew dramatically because of increased earnings from television and commercials. RBK thus became the richest and dominating club in Norway, but still professed an intention to recruit mainly local players.

Method: The investigation will focus on the period from 1999 to 2008, and take a historical perspective. It will therefore focus on changes in the discursive construction of what it means to be "trønder", i.e. from the region of Trøndelag. The paper investigates the struggle to construct "trønder" as it is played out among fans on rbk.no and kjernen.no. Discursive analysis is applied to selected texts published online. These texts are compared with discussion and interviews in the dominating regional newspaper Adresseavisen. In addition, key members of both RBK and Kjernen have been interviewed.

Results and Discussion: This changed gradually after approximately 1999 when more and more international players joined the club. In 2007 RBK sometimes fielded a team of one Canadian, one Fin, two Swedes, one Slovakian, two Ivorian and one from Burkina Faso, in addition to three or four Norwegians. This development stimulated a heated debate among fans, journalists and members of the club (still run and owned by members). Some, like the former coaches Nils Arne Eggen and Ola By Rise, claimed that the club would be best served by maintaining a majority of locally or regionally raised players, "trøndere", with whom local audience could identify. Others felt that the new multicultural outlook of the team could help include excluded or marginalized groups in the local community, thereby aiding a necessary re-construction of the local imagined community. Some of the most dedicated fans in the group called "Kjernen" began using "trønder" as an honorary title, not given only to those born or raised in Trøndelag, but, for instance, also to African or Latin-American players found to "deserve" it because of their display on the field.

SPORTS DEVELOPMENT AID: THE CASE OF NORWAY AND TANZANIA

STRAUME, S.

NORWEGIAN SCHOOL OF SPORT SCIENCES

In 1983 the Norwegian Confederation of Sports, NIF, implemented a rather ambitious sports development project, "Sport for All", aiming to help building sport structures in and around the city of Dar es Salaam, Tanzania.

This paper examines the motives and means for the first Norwegian sports aid to a developing country in the early 1980's, and aims to place the sports aid in a wider context outside the sports field. The main research questions are; a) What were the motives and means for the Norwegian Confederation of Sports to initiate a sport development aid project in Africa in the 1980's?; b) What kind of arguments characterized the internal discussions about the sports aid? c) How did the sports aid fit with the development aid policy of the Norwegian government at the time? And finally; d) How can we understand and explain the relationship between the Norwegian Confederation of Sports as donor and the Tanzanian Sport Council as recipient?

In-depth archival studies at the Norwegian Confederation of Sports (NIF) and the Norwegian agency for development cooperation (NORAD) as well as public documents are the empirical base of this study, and document analysis was used to examine the policies and major decisions of NIF as the implementing party. These have been supplemented by interviews with key actors involved in the first Norwegian sport aid project, both within NIF, NORAD and the Tanzanian Sport Council.

There were several motives for NIF to engage in sports development aid, and the most conspicuous ones seem to have been the perception that Norwegian sport "as an industrialised country in regards to sport" had something to offer to the developing world. The fact that other Nordic countries also initiated sports aid is likely to have been an important motive for the Norwegian involvement. Further, the sports aid was an obvious result of ongoing changes in the political strategies of Norwegian development aid, which made funds available for private organisations with development projects. Hence the arguments for initiating sports aid had to fit with NORAD's priorities. This is reflected in the public documents: the rhetoric used in the sports aid discussions is clearly in line with the development aid jargon at the time.

When discussing the relationship between NIF as donor and the Tanzanian Sport Council as recipient, I make use of the term power effects, which explains that power appear as a result of relations, and can not in itself be used as the explanation to such relations. I ask whether such power effects were created by NIF, and what impact this may have had on the sports aid relationship.

THE HISTORY OF SPORTS TRAINING AND COACHING IN NORWAY WITH PARTICULAR FOCUS ON THE NORWEGIAN COACH STEIN JOHNSON.

NIESEN, J.J.

NORWEGIAN SCHOOL OF SPORT SCIENCE

Introduction: Cox (2008) mentioned in his review of Polley's (2007) introduction in Sport History, that the only thing missing is more insight in research issues like the history of sports training. However, there is not much research on that topic by sport historians.

In 2007 the Norwegian sports coach Stein Johnson, delivered his private archive to the National Coaching Centre and the Norwegian School of Sport Science in Oslo. Johnson was successful in sports coaching within 11 sports during his about 43 year long career as a trainer. This paper is based on research that tried to explain his success and influence on coaching in Norway. With describing the development of sports training science and practice in a national and international perspective, I tried to set Johnson's work in a national and international frame.

Methods: Krueger (1996) names four approaches for insight on the methodology of the history of Sports Coaching. This study is based on literature analysis, biographies and oral history. The main source was the archive of Stein Johnson.

Leading works on Sports History in Norway barely mention the history of sports training and coaching (Olstad, 1987; Tønnesson, 1986; Goksøyr, 1991; 2008). In addition, articles from history and coaching science build the basis for the history of coaching part.

Results: My research showed that psychological and pedagogical skills were the main reasons for the success of Johnson. He developed a basic training plan for the ice skaters, which he adapted later to several other sports. Main research about the development and history of sports coaching in Norway showed, that this nation was competent in adapting and developing new training methods from other countries.

Discussion: This study shows that the personality and individual work of coaches is apparently for sport practice much more important as theoretical skills and developments in sport science and physiology. That means that a history of coaching can not just look at textbooks and scientific articles but also depends on oral history. Combination of qualitative and quantitative research methods are nearly indispensable.

OP-RE01 Rehabilitation 1

DIFFERENCES IN STRENGTH AND JUMPING TECHNIQUE BETWEEN ACL-RECONSTRUCTED AND NON-INJURED HAND-BALL PLAYERS

KRISTIANSLUND, E., MYKLEBUST, G., SHIMA, Y., BAHR, R., KROSSHAUG, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: About one third of ACL-injured elite handball players are unable to return to their pre-injury sport participation level. It is still unclear to what degree the ACL-reconstructed athletes returning to sports regain symmetrical landing patterns and thigh strength after rehabilitation. Altered motion patterns and side-to-side differences may predispose players to new ACL injuries. Based on this we investigated differences in strength and knee motion between legs in ACL-reconstructed handball players and differences in knee motion between ACL-reconstructed and non-injured handball players.

Material and Methods: All players in the Norwegian female elite handball series were invited for testing and 184 players (about 85%) were tested. Of these, 20 players had an unilateral ACL reconstruction (mean time since injury 3.5±2 (SD) yrs, 8 patellar and 12 hamstrings grafts). These were matched with twenty uninjured players (age 24.5±4.6 vs. 24.3±4.3 years, height 176.2±6.9 vs. 175.8±6.0 cm). All test subjects were fit for match play on the day of testing. The players completed maximal isokinetic quadriceps and hamstrings strength testing at 60 °/s. An eight-camera motion analysis system captured the motion of three maximal 30 cm vertical drop jumps at 240 Hz. Key kinematic and kinetic values were calculated and the average of three jumps was used for all analyses.

The ACL-reconstructed leg of injured players was compared with the uninjured leg using paired t-tests. The averages of both legs were compared between groups using independent t-tests.

Results: When comparing legs of previously injured players, the ACL-reconstructed leg had lower quadriceps (170.2±6.5 (SEM) Nm vs 181.6±5.8 Nm, p=0.046) and hamstrings (100.6±5.8 Nm vs 108.6±4.8 Nm, p=0.012) strength. For the drop jumps no differences were found between legs for maximal knee joint moments or maximal knee joint moments during the first 50 ms.

Significant differences in knee flexion at initial contact were found between the groups of players. The ACL-reconstructed group landed with less knee flexion compared to the non-injured group (29.6°±1.4° vs 34.6°±1.4°, p=0.015), but there was no difference in valgus angles at initial contact. ACL-reconstructed and non-injured players displayed similar values of maximum knee flexion and knee valgus as well as maximum knee flexion moment (211±8 vs 204±11 Nm, p=0.605) and valgus moment (38±6 vs 40±5 Nm, p=0.779) during landing phase.

Conclusion

ACL-reconstructed players display significant strength differences between legs, with the reconstructed leg being weaker than the uninjured leg. This suggests that rehabilitation before return to sport may be inadequate. Despite the strength imbalances, the injured players display symmetrical motion patterns an land similar to non-injured players, with an exception of knee flexion at landing. This may protect against new injuries, although differences in joint loading patterns may be revealed with more demanding tasks.

MEDICAL INFRARED THERMOGRAPHY AS A SCREENING TOOL FOR KNEE INJURIES IN PROFESSIONAL JUNIOR ALPINE-SKI-RACERS IN AUSTRIA – FINDINGS OF A PILOT STUDY

HILDEBRANDT, C.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Medical Infrared Thermography (IFT) is a non-radiating and non-invasive analysis tool for physiological functions related to skin-temperature control. In the past it has been successfully used in veterinary medicine for injury prevention and management in race horses (TURNER et al. 2000). Any significant asymmetry of more than one degree centigrade from two sides of the body may indicate a pathophysiological process. Knowing that similar anatomical and physiological conditions exist, it can be assumed that IFT is a helpful to manage injuries

in human athletes. But there is a lack of evidence, demonstrating the successful use with the advantage of twenty first century technology (DIAKIDES 2008).

The knee is a weak link and the frequently affected in alpine skiing (PUJOL et al 2007). Long-term consequences such as osteoarthritis and high treatment costs raise safety concerns.

Valid and reliable measurements are crucial to evaluate IFT as a screening tool in the prevention, diagnosis and rehabilitation of knee injuries in athletes. For this purpose the standardisation methods, proper recordings and the optimal image analysis were defined.

METHODS: We conducted a pre-season measurement of 35 female and 52 male junior alpine ski racers (non-injured, previous injury and acute injury) aged 14-19 years from the "Skigymnasium Stams". After an acclimatisation period of 20 minute we recorded an image of the anterior/posterior and medial/lateral aspect of both knees with an infrared camera (TVS500EX). To analyse the images we used the software GORATEC Thermography

Studio Report. A physiotherapist examined the functional aspect of the knee.

RESULTS: In 6 male athletes intra-individual thermal asymmetries of 1.4 (±0.58) degree Celsius over the tibia revealed overuse reactions such as Osgood-Schlatter disease. The clinical examinations confirmed these findings. The evaluation of 7 feminine and 1 male athlete with an operation of the knee over the last 6 months clearly demonstrated the localisation and extent of the affected area.

DISCUSSION: This study was instrumental in learning how to use the technology. It clarified the potential of IFT for a more objective and uncomplicated evaluation of knee injuries. Pre-season measurement will be compared with post-season measurements to evaluate the physical stress.

In case of thermal asymmetries of more than one degree Celsius they will be analysed with structural measurements such as magnetic resonance imaging and X-ray. These results can be used to adjust the training programs of the at-risk athletes and may lessen the severity and frequency of overuse and acute knee injuries.

THE COL12A1 GENE IS ASSOCIATED WITH INCREASED RISK OF ANTERIOR CRUCIATE LIGAMENT RUPTURES IN FEMALES

POSTHUMUS, M., SEPTEMBER, A., O'CUINNEAGAIN, D., VAN DER MERWE, W., SCHWELLNUS, M., COLLINS, M.
UNIVERSITY OF CAPE TOWN

Introduction: Anterior cruciate ligament (ACL) ruptures are among the most severe musculoskeletal soft tissue injuries. However, the exact mechanisms which cause these acute injuries are unknown. Recently, two genes, namely COL1A1 and COL5A1, which code for the {alpha}1 chain of type I collagen, and the {alpha}1 chain of type V collagen respectively, have been shown to be associated with increased risk of ACL ruptures. The TT genotype of the functional COL1A1 Sp1 binding site polymorphism was under-represented in participants with ACL ruptures when compared to the control participants, whereas the CC genotype of the COL5A1 BstUI restriction fragment length polymorphism (RFLP) was significantly over-represented in the female control participants when compared to female participants with ACL ruptures. Type XII collagen, similarly to type I and type V collagen, is a structural collagenous component of the most basic unit of ligament, the microfibril. Type XII collagen is a homotrimer consisting of 3{alpha}(XII) chains, which are encoded for by a single gene, COL12A1. Therefore the aim of this study was to investigate whether sequence variants within a third gene, namely COL12A1, are associated with ACL ruptures.

Methods

129 subjects with clinically and surgically diagnosed ACL ruptures, as well as 216 physically active controls subjects (CON) without any history of ACL injury were included in this case-control genetic association study. All subjects were genotyped for the previously characterised non-synonomous AluI and BsrI RFLPs within exon 65 and exon 29 respectively.

Results: There was a significant difference in the genotype frequency between the ACL and CON groups among the female, but not the male participants. The AA genoptype of the AluI RFLP was significantly over-represent in the female ACL participants (OR=2.4, 95% CI 1.0 – 5.5, P=0.048). There were no genotype effects between the ACL and CON group for the BsrI RFLP.

Conclusion

The COL12A1 AluI RFLP is associated with ACL rupture in females. The results suggest that females with an AA genotype are at increased risk of ACL ruptures. These initial genetic-association studies should be further investigated and if confirmed, incorporated into multifactorial models developed to identify predisposed individuals.

FUNCTIONAL PERFORMANCE AND SELF-REPORTED KNEE FUNCTION IN MENISCECTOMIZED PATIENTS 2 YEARS AFTER SURGERY COMPARED TO AGE- AND GENDER MATCHED CONTROLS.

THORLUND, J.B., AAGAARD, P., ROOS, E.M.
UNIVERSITY OF SOUTHERN DENMARK

INTRODUCTION: Meniscectomized patients have a high risk of developing knee osteoarthritis (1). Furthermore, decreased muscle function is thought to play a key role in disease development and progression (2). Previous studies on muscle function in meniscectomized patients have used the non-operated leg as a healthy control, possibly underestimating any bi-lateral impairment.

Purpose: To identify differences in functional performance tests and self-reported pain, function and knee-related quality of life between meniscectomized patients and age- and gender matched controls.

METHODS: Patients: Thirty-one patients (21 men, 46±6 yrs, 175±7 cm, BMI 26±4, 21±6 month post-surgery) operated for a non-traumatic medial meniscal posterior horn tear. Thirty-one controls (19 men, 46±6 yrs, 175±10 cm, BMI 26±4) identified through the social security number system. Strict in-/exclusion criteria were followed for both groups.

Self-reported outcomes: The Knee Injury and Osteoarthritis Score (KOOS) were used to assess knee-related pain, symptoms, function in daily life, sports and recreation function and quality of life (3). Separate subscale scores from 0 to 100, worst to best, were calculated.

Functional performance tests: One-leg hop for distance and maximal number of knee bendings/30 s (4). Mean of both legs were calculated for the controls.

Correlations: To determine if self-reported and objectively measured physical function represent similar constructs correlations were calculated between all KOOS subscales and the two functional tests.

RESULTS: KOOS: Large differences were observed between patients and controls; Pain 83±16 vs. 97±5 ($p<0.001$), symptoms 82±16 vs. 94±9 ($p<0.001$), ADL 89±14 vs. 99±3 ($p<0.001$), Sport/Rec 69±24 vs. 95±8 ($p<0.001$), QOL 69±23 vs. 91±11 ($p<0.001$).

One-leg hop: No difference between operated vs. healthy leg in patients (83±30 vs. 85±28 cm, $p=0.33$) and no significant difference compared to controls (83±30 vs. 91±24 cm, $p=0.27$).

Knee bendings/30 s: No difference between operated vs. healthy leg in patients (26±10 vs. 26±9, $p=0.56$) and no significant difference compared to controls (26±10 vs. 29±10, $p=0.24$).

Correlations: Moderate correlations were identified between all KOOS subscales and maximal number of knee bendings/30 s ($r=0.39$-0.49, $p=0.03$-0.006) in the patient group.

CONCLUSION

Self-reported outcomes were significantly worse in meniscectomized patients compared to controls at 2 yrs post surgery. Similarly, clinically relevant differences of ~10 percent were seen in functional tests though not reaching statistical significance. KOOS scores were best

reflected in the maximal number of knee bendings/30 s test suggesting that this test resembles self-reported knee function in meniscectomized patients.

ACL INJURED AND UNINJURED PROFESSIONAL ALPINE SKIERS- A DESCRIPTIVE COMPARATIVE STUDY ON POSSIBLE INTRINSIC AND EXTRINSIC RISK FACTORS

WESTIN, M.
THE SWEDISH WINTER SPORTS RESEARCH CENTRE

Background: Alpine skiing is a very popular sport for children and adolescents. However, it is not without risks of injuries. The majority of injuries in alpine skiing are knee sprains and in particular anterior cruciate ligament (ACL) injuries, which is the most serious one. An ACL injury has consequences for the athlete, in terms of lost time from sports and a great risk for osteoarthritis in the future. The most optimal injury prevention program should be based on both intrinsic and extrinsic risk factors.

Aim of study: The aim of this study was to describe possible intrinsic- and extrinsic risk factors for ACL injuries related to professional alpine skiers.

Subjects and Methods: In this study, ongoing for forth years, we are prospectively following all alpine ski students from all Swedish Ski High Schools, in order to define injury risk factors. Prior to each ski season the skiers have been clinically examined, according to a specific protocol including control of general joint laxity, knee alignment, anterior knee laxity, muscle flexibility and three different functional performance hop tests for instance. Then the skiers were prospectively followed in terms of ACL injuries, during the ski season.

Results: Preliminary results will be present from this ongoing study. The study has been ongoing for four years.

IS-SS02 Reconceptualising sports coaching: A sociological endeavour?

'RECONCEPTUALISING SPORTS COACHING: A ROLE FOR SOCIAL THEORY?'

JONES, R.L.
UWIC/NSSS

Recent research has begun to argue that at the heart of coaching lies a sociological endeavour. It is based on the premise that coaching, as opposed to being a knowable sequence, is fundamentally intertwined with social perceptions at the micro-interactive level within given situational constraints. Taking such a position as a starting point, the general purpose of this symposia, and of this introductory presentation in particular, is to (a) question the legitimacy of such a position; (b) strengthen the primary case made; and (c) demonstrate how previously under-discussed sociological theories (e.g., social exchange theory) can contribute to our understanding of sports coaching.

STOCKS OF KNOWLEDGE AND SOCIAL POSITIONING: USING GIDDENS' WORK TO UNDERSTAND COACHING

PURDY, L.
UNIVERSITY OF LIMERICK

As the social complexities inherent in sports coaching are being increasingly recognised (e.g., Purdy, Potrac & Jones, 2008), researchers are drawing on strands of social thought to better understand the activity. The use of sociological theories and perspectives are aimed at gaining a deeper understanding of coaching by appreciating the social networks and values within each context. For example, Giddens' (1979) work on stocks of knowledge and social positioning demonstrates the importance of social expectations between coach and athletes. Here, preliminary findings indicate that such expectations have to be at least partially met if the coaching contract is to be honoured. Not meeting expectations in relation to actions associated with individuals' social positionings puts at risk the respect of athletes, without which coaches simply cannot operate (Jones, 2006). This on-going work extends previous research in coaching by examining the various layers of social interaction within it, thus stressing the interdependent, problematic nature of the coach-athlete relationship.

HOW CAN LUHMANN'S COMMUNICATION THEORY INFORM SPORTS COACHING?

RONGLAN, L.T.
NORWEGIAN SCHOOL OF SPORT SCIENCES

The German sociologist Niklas Luhmann developed a theory (systems theory) which does away with the notion of system in all its traditional wordings. Luhmann's theory is not about control or determinism but rather the opposite, namely the non-linear, contingent, temporal and rather surprising rise of order out of chaos. As a sociological theory it is a theory about complexity and communication. Luhmann insisted that one does not locate society inside individuals, but between them. Thus, the fundamental unit of society is communication, not the single actor. And communication cannot be reduced to the thoughts of Ego and Alter; it represents something else; a third dimension, which both parties observe while communicating, and through which they understand each other. Communication presupposes individuals – it does not take place beyond, outside or separate from individuals. But humans are more than communication, and communication is more than action and consciousness.

Based on this theoretical perspective, the aim of the paper is to look at coaching in sport as communication processes. The paper has a threefold intention. First, given that Luhmanns texts to a little extent are accessible in English, his notions communication, complexity, and system will be outlined. Second, I will state the reason for why a shift from action to communication as the key concept may be suitable for grasping more of the complexity in coaching situations. Finally, the limitations imposed by linear models will be discussed, and I will argue that communication theory is less reductionist: it enables a closer look at the ambiguities and the diversity that mark social interaction.

IS-SM01 Physical activity during pregnancy and after childbirth

EVIDENCE FOR EXERCISE IN PREVENTION AND TREATMENT OF PREGNANCY-RELATED LOW BACK

STUGE, B.

OSLO UNIVERSITY HOSPITAL, ULLEVÅL, OSLO

Introduction: Pain in the lumbo-pelvic area is a widespread problem of pregnancy. About 50% of pregnant women suffer from low back pain (LBP) or pelvic girdle pain (PGP) during pregnancy. PGP is stated to be an identifiable form of LBP that can occur separately or in conjunction with LBP 2. The prevalence of PGP during pregnancy is 20 %. Most women recover after delivery, especially in the first month after delivery; however studies indicate that about 7 % still suffer from PGP postpartum. Suggestions to help manage the womens' pain and disability are varied and include different kind of treatment regimes, exercises being one of them. The question is on what evidence are the treatments and exercises based?

Method: This review included randomised controlled trials. Methodological quality was assessed using a quality assessment form for internal validity. For identifications of studies a search strategy was used for relevant databases.

Results: For treatment of pregnant women ten RCT's were identified; one of them examining prevention of LBP and/or PGP. Three RCT's examining postpartum LBP and/or PGP were found. The methodological quality of the studies for pregnant women tended to be rather poor with potential for bias in the results. Those who participated in an exercise program in addition to their prenatal usual care, regardless of the treatment program, reported less intense pain than those who received usual care alone. However, one cannot rule out a possible placebo effect in studies that looked at usual prenatal care (no treatment) versus active participation in exercise programs. Interventions, subjects included and outcomes were not sufficiently similar to perform a meta-analysis to determine size of effect. The studies examining postpartum LBP and/or PGP showed high methodological quality. However, only one study demonstrated statistically and clinically significant positive and long-lasting effects 1. The treatment program studied focused on exercises for motor control and stability of the pelvic girdle.

Discussion: Good methodological quality of a study is important to rely on the results. The quality of the interventions studied is another important aspect to consider when evaluating the results of an effect study. Many questions are then to be raised. How to exercise with PGP? Is stabilizing exercises the answer? Are there any exercises and movements women with PGP should avoid? Why did the study by Stuge and co-workers 1 show long-lasting effects of 11 individual treatments and exercising for 20 weeks?

THE IMPACT OF MATERNAL LIFESTYLE ON CHRONIC DISEASE RISK.

MOTTOLA, M.

UNIVERSITY OF WESTERN ONTARIO

Obesity and diabetes have reached epidemic proportions in our society today. Recent literature has suggested that the maternal environment plays an important role in the future risk of chronic disease in the offspring. Infants of obese or gestational diabetic women are at risk for obesity, type 2 diabetes and cardiovascular disease later in life. Large for gestational age babies and small for gestational age babies are on the extreme ends of the birth weight continuum and are most often born to obese and gestational diabetic women. These babies are at risk for chronic diseases later in life. Gaining excessive weight during pregnancy and then retaining weight during the postpartum period may also contribute to the obesity crisis, especially for women of reproductive age. Women with gestational diabetes are at risk for type 2 diabetes later in life. Maternal lifestyle, including eating a healthy diet and being active during pregnancy can prevent excessive weight gain and prevent gestational diabetes. In addition, providing a healthy fetal environment may help prevent childhood obesity and reduce the risk of chronic disease later in life. We have developed a Nutrition & Exercise Lifestyle Intervention Program (NELIP) that is an effective tool for preventing excessive weight gain and gestational diabetes in overweight and obese pregnant women. Preventing excessive weight gain during gestation improves glucose tolerance and provides a healthy environment for fetal growth and development. Perhaps childhood obesity may be prevented by initiating a healthy lifestyle started early in life through pregnancy and in the first year postpartum.

Healthy mothers = healthy babies = healthy futures!

THE EFECT OF PREGNANCY AND CHILDBIRHT ON PELVIC FLOOR FUNCTION AND THE NEED FOR STRONG PELVIC FLOOR MUSCLES IN SPORT

BØ, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

The pelvic floor muscles (PFM) forms the floor of the abdominal cavity, and are essential in closure of the pelvic openings. They should automatically contract before and during increase in abdominal pressure and form a structural support for the pelvic organs. Pelvic floor dysfunction may lead to urinary incontinence, fecal incontinence, pelvic organ prolapse, sensory and emptying abnormalities of the lower urinary tract, defecatory problems (constipation), chronic pain syndromes and sexual disorders. During pregnancy and after childbirth hormonal changes with loosening of the connective tissue, weight of the baby and stretching and tears of the connective tissue, musculature and peripheral nerves increases the risk of pelvic floor dysfunction. Theoretically high impact activities and activities increasing intra-abdominal pressure eg heavy weight-lifting during pregnancy may add to this risk. Since stress urinary incontinence occurs during increase in abdominal pressure, one would expect that female elite athletes in general are at risk. The prevalence during sports among young, nulliparous elite athletes varies between 0% (golf) and 80% (trampolinists). The highest prevalence is found in sports involving high impact activities such as gymnastics, track and field, and some ball games. A "stiff" and strong pelvic floor positioned at an optimal level inside the pelvis may be a crucial factor in counteracting the increases in abdominal pressure occurring during high-impact activities.

There are no randomised controlled trials or reports on the effect of any treatment for stress urinary incontinence in female elite athletes. However, strength training of the pelvic floor muscles has been shown to be effective in treating stress urinary incontinence in parous females in the general population. In randomised controlled trials, reported cure rates, defined as <2g of leakage on pad tests, varied between 44% and 80% (1). To date there are 4 RCTs evaluating the effect of antenatal pelvic floor muscle training. Three of these studies show favourable results. The study showing no effect included only one session with the physiotherapist. There are 3 RCTs and one matched controlled study in prevention of urinary incontinence postpartum, all but one show positive results (3). The matched controlled study demonstrated 50% less women with urinary incontinence in the exercise group. The study with no effect used a very weak intervention with only 3-4 visits with a midwife. Pelvic floor muscle training has no serious adverse effects and has been recommended as first-line treatment in the general population. Use of preventive devices such as vaginal tampons or pessaries can prevent leakage during high impact physical activity. The pelvic floor muscles need to be much stronger in elite athletes than in other women. There is a need for more basic research on pelvic floor muscle function during physical activity and the effect of pelvic floor muscle training in female elite athletes.

IS-PH03 Cross-Country skiing

THE COMPETITIVE XC SKIER - FROM AN INTEGRATIVE PERSPECTIVE

HOLMBERG, H.C.

SWEDISH WINTER SPORTS RESEARCH CENTRE

Cross-country skiing (XC) is a demanding endurance sport. The skiers compete on hilly tracks with a combination of steep uphill, flatter terrain and technically demanding downhills. This imposes physiological as well as coordinative challenges due to the frequent transitions between, and the use of, different skiing techniques. During the last decade there has been an increased scientific emphasis on upper body development (1) and biomechanical modifications to different skiing techniques (2-4). The greater emphasis on upper body training has markedly improved skiers' endurance and muscle strength in the arm and torso region. Furthermore, the innovative technical development of specific techniques has contributed to higher racing velocities (3, 4) and a better use of energy (2). Although there has been considerable progress in overall XC performance during the last years, the new demands of the sprint and mass-start events imply further improvements. One potential area for development is increasing the understanding of the XC race and its components. Recent development of more advanced methodology in the lab and the integrative use of physiological and biomechanical methodologies have contributed to better and more circumstantial analysis of several determining aspects of the sport. Areas that would be interesting to explore more specifically in the field are the velocity profile, technique transitions and the dynamics of different physiological, as well as biomechanical, variables in races using different ski techniques and of varying duration. This has the potential to improve our understanding of the demands of the sport, but also the importance of recovery during continuous intermittent exercise, as well as the development of fatigue. A closer cooperation between sports science and the rapidly growing research field of sports/performance technology has the potential to provide new possibilities and perspectives. A key factor in athletes' success will always be improving their physiological capacities, but also the more effective use of biomechanical knowledge to optimise technical performance, assisted by better equipment, for example. In this context the use of an integrative biomechanical and physiological approach is an important tool towards greater understanding and enabling further improvements to XC performance.

LACTATE IN WHOLE BODY EXERCISE; AN ANAEROBIC END PRODUCT AND AN AEROBIC SUBSTRATE

VAN HALL, G.

RIGSHOSPITALET

Lactate in whole body exercise; an anaerobic end product and an aerobic substrate

G van Hall

Department of Biomedical Sciences, University of Copenhagen & Metabolic Mass-Spectrometry Facility, Rigshospitalet, Copenhagen, Denmark

Lactate has been considered a dead end waste product of glycolysis due to hypoxia and a major cause of fatigue. The produced lactate thought to be cleared by the liver for gluconeogenesis. However, it has become clear that skeletal muscle continuously produces lactate, and during exercise without an apparent lack of oxygen. The increase of lactate production with exercise is depending on the acceleration of glycolysis causing and increase in pyruvate and NADH concentration that will shift the equilibrium enzyme lactate dehydrogenase to lactate formation. Moreover, during exercise the active muscles are by far the most important tissue for lactate uptake and subsequent oxidation. Thus, the muscle net lactate release, and to a large extent the systemic lactate concentration, is depending on the balance between the active muscle lactate production and simultaneous utilization. This concept becomes very clear during diagonal stride roller-skiing at about 75% VO2max (van Hall et al., 2003). A relative small increase in arterial lactate (~2.5 mmol/L) occurs despite a very high whole body lactate production (~14.1 mmol/min) caused by the large release of lactate by the arms and legs. However, the legs are taking up and oxidizing substantially more lactate than they produce. Thus, due to the large leg muscle mass and energy requirements for contraction the legs are able to clear and oxidize most of the lactate that is produced during diagonal stride roller skiing keeping systemic lactate concentrations low. In addition, the arms showed to be equally efficient in lactate utilization per kg of muscle than the legs, however, the arms produced far more lactate than they consumed, i.e. are more glycolytic than legs. These findings imply that systemic lactate levels are no measure for aerobic/anaerobic capacity of athletes in different sport disciplines. Moreover, sports that use both the arms and the legs like rowing, swimming and cross-country skiing the lactate levels will depend on the relative utilization of arms versus legs. This implies that blood lactate levels cannot be used to evaluate training status or technique (Mittelstadt et al., 1995; Larson, 2006).

SPRINT COMPETITIONS AND MAXIMAL SPEED IN CROSS-COUNTRY SKIING - A PHYSIOBIOMECHANICAL UPDATE.

STÖGGL, T., MÜLLER, E., HOLMBERG, H.C.

UNIVERSITY OF SALZBURG, MIDSWEDEN UNIVERSITY

Due to the recent introduction of sprint races and an increasing number of mass start competitions in the World Cup series, new aspects of training and testing are becoming fields of research. This could be attributed to the upcoming specialization of athletes in sprint racing, as well as to the technical modifications demonstrated for selected techniques, eg. double poling (Holmberg et al. 2005) and double-push skating (Stöggl et al. 2008a). Both technical modifications were found to be superior to the conventional skiing style. In addition, the mean skiing velocity in WC sprint races has shown a steady increase in skiing speed (Stöggl et al. 2008b), reaching mean race speeds of up to 9.5m/s in classical style and up to 10m/s in skating. It should be noted that skiing speeds in the majority of scientific studies are quite apart to these values. It was demonstrated that there is a moderate to high correlation between sprint performance and performance in distance races (Stöggl et al. 2008b).

It was recently shown that short duration maximal skiing speed and specific maximal and explosive strength are good predictors of cross-country skiing sprint performance (Stöggl et al. 2007a,b 2009). Interestingly it was found that skiers with higher maximal power output and maximal skiing speeds showed, in addition to their higher performance, less fatigue during all-out tests of the same duration as a sprint race. These results may be coupled to the prerequisites of modern sprint techniques, as characterized by high peak forces and high force impulses over a short time. The combination of high force output over a short time and thus a longer recovery time was found to be faster and more economical (Holmberg et al. 2005; Stöggl&Müller 2009). Furthermore, it was found that cycle length but not cycle rate was related to performance, especially at submaximal velocities. This was particularly true of the V2 technique and diagonal stride, whereas in double-poling there seems to be an optimum cycle length and cycle rate pattern (Stöggl&Müller 2009). Measures of aerobic capacity (VO2max) showed only low correlations to sprint performance. However, it should be noted that a high level of VO2max should be the basis but also that other factors that are mainly associated with neuromuscular factors and anaerobic capacity discriminate between weak and strong sprint skiers.

These findings should lead to a reconsideration of concepts in the training and testing of cross-country skiers. In addition to common VO2max and incremental step tests, also strength and speed tests should be included. Maximal and explosive strength training sessions could also be useful additions to conventional aerobic and strength endurance training.

MUSCLE FATIGUE IN ELITE CROSS COUNTRY SKIERS; A LINK BETWEEN SARCOPLASMIC RETICULUM FUNCTION AND GLYCOGEN AVAILABILITY?

ØRTENBLAD, N.

UNIVERSITY OF SOUTHERN DENMARK

The consistent observations that muscle glycogen (Gly) stores at the beginning of exercise are closely related to endurance capacity and that the point of exhaustion after prolonged exercise coincides with low muscle Gly levels clearly suggest a role for muscle Gly in fatigue (Hermansen et al. 1967). However, the link between Gly and impaired muscle function during fatigue is not well understood and a direct cause-and-effect relationship between Gly and muscle function remains to be established. Here presented a system where events in the excitation-contraction (E-C) coupling are affected by Gly content and localisation.

We examined the effect of Gly content on the sarcoplasmic reticulum (SR) function in the arm and leg muscles of elite cross country skiers (n=10, VO2max 72 ml kg-1 min-1), before, immediately after, and 4h and 20h after a fatiguing 15-km race. During the first 4hrs of recovery the skiers received either water or carbohydrate (CHO), and thereafter the same CHO enriched food. Straight after the race arm Gly was reduced to 31±4% and the SR Ca2+ release rate had decreased to 85±2% of their initial levels. After a 4h recovery with CHO, the SR Ca2+ release rate was fully normalized and Gly had noticeably recovered (59±5% initial). However, if CHO was absent during the first 4h recovery, the muscle Gly and the SR Ca2+ release rate remained low and reduced (29±2% and 77±8%, respectively), with both parameters being normalized after the remaining 16h recovery with CHO. Leg muscle Gly decreased to a lesser extent (71±10% initial) and there were no effects on the SR Ca2+ release rate. Importantly, these data demonstrate a strong association between low Gly levels and muscle E-C coupling even after long recovery periods where adenine nucleotide levels may be normalised. Additionally, SR function is estimated in vitro under constant energy levels. Thus, although related to muscle Gly levels, the impaired SR function is not due to a diminished energy metabolism at low Gly levels.

In line with this, transmission electron microscopy (TEM) reveals that Gly is located in distinct compartments close to different sites of E-C coupling (Marchand et al. 2002). We have shown that 72±3% of intramuscular Gly is located in the intermyofibrillar space (between the myofibrils) and 28 ± 3% in the intramyofibrillar space. Additionally, in single fibres the intramyofibrillar Gly content is positively correlated with fatigue resistance capacity, and intermyofibrillar Gly is inversely correlated with tetanic half relaxation time.

Together, these results demonstrate that two distinct subcellular populations of Gly have different roles in contracting single muscle fibres. This is consistent with the idea that the Gly localisation modulates the E-C coupling, thereby affecting muscle contractility and fatigability.

Effects of maturation on the relationship between speed and endurance in circum-pubertal soccer players

Mendez-Villanueva, A.1, Kuitunen, S.1, Peltola, E.1, Poon,TK.1, Simpson, B.1

1: Performance Enhancement and Talent Identification Section, ASPIRE Academy for Sports Excellence (Doha, Qatar)

Introduction: Morphological and physiological considerations suggest that sprinting ability and endurance capacity put conflicting demands on the design of a human's locomotor apparatus and therefore cannot be maximized simultaneously (Van Damme et al., 2002). However, in children the ability to demonstrate this specialization is less apparent (Rowland, 2002). That is, children who perform well in sprinting tasks also perform well in endurance activities. In this regard, it has been suggested that specialization into endurance or sprinting "types" occurs during late-puberty stages (Falk and Bar-Or, 1993). However, few studies have assessed these associations in children and adolescents of different maturational levels spanning a wide circum-pubertal spectrum. Moreover, the ability to demonstrate this specialization has yet to be tested in young soccer players where players are expected to be selected and/or trained to develop both qualities (i.e., speed and endurance) (Reilly et al., 2000). In the present study we aimed at determining whether maturation affects the relationship between sprinting speed and endurance in a group of circum-pubertal soccer players.

Methods: Sprinting speed and endurance capacity were measured in 14 early-pubertal male soccer players (16.9 ± 0.7 yr old; mean ± SD), mid-pubertal male soccer players (14.3 ± 0.9 yr old) and 26 late-pubertal male soccer players (12.3 ± 0.7 yr old). Each player performed an incremental field test to exhaustion for the determination of maximal aerobic speed (MAS) (i.e., endurance capacity) and a 40-m running sprint test for the assessment of maximum sprinting speed (MSS). Relationships between size-corrected MSS and MAS measures were examined.

Results: MSS was correlated with MAS (r = 0.66 ± 0.15; 95% confident limits, moderate to very large). The MSS/MAS ratio did not differ among the three groups; early-pubertal soccer players (1.16 ± 0.06; mean ± SD), mid-pubertal soccer players (1.18 ± 0.07) and late-pubertal soccer players (1.16 ± 0.06).

Discussion: Within this cohort of highly trained young soccer players, which spans a wide circum-pubertal spectrum, speed and endurance capacity coevolved. In conclusion, the development of sprint capacity appear not to be constrained by the need of endurance capacity and vice versa.

EFFECT OF EXTREME ENVIRONMENTAL CONDITIONS ON PHYSICAL ACTIVITY PATTERNS OF SOCCER PLAYERS

OZGUNEN, K., KURDAK, S., CIGDEM, Z., KORKMAZ, S., YAZICI, Z., ERSOZ, G., BINNET, M.
ÇUKUROVA UNIVERSITY, TURKEY, ANKARA UNIVERSITY, TURKEY

Soccer teams may sometimes be obliged to play under difficult environmental conditions. Activity patterns of players of different standards have been analyzed by time-motion analysis, but there is dearth of knowledge how the players' match performance is affected by environmental conditions.
Purpose: This study aimed to evaluate changes in the activity patterns during a soccer match played in different conditions of environmental temperature and humidity.
Methods: Non-acclimatized soccer players (n=10, the goal keeper was excluded, 20 ±2 y, V'O2max=63 ±7 ml/min/kg) played 2 matches in different environmental conditions. Players ingested telemetric core temperature (Tc) sensors prior to each match and wore a heart rate (HR) and global positioning system (GPS) monitor during the match. A computer based analysis program was used to evaluate heart rate and speed changes during the match. The following locomotor categories were used: standing (0 – 0.4 km/h), walking (0.5 – 7.5 km/h), jogging (7.6 – 14.5 km/h), low – moderate running (14.6 – 19.5 km/h), high speed running (19.6 – 25.5 km/h) and sprinting (> 25.6 km/h). These were later divided into five categories: (1) standing; (2) walking; (3) running, encompassing jogging and low – moderate intensity running and (4) high intensity running, consisting of high speed running and sprinting.
Results: The average ambient temperature for the June 2007 match was 34 ± 1 ⁰C with a relative humidity of 38 ± 2 %. In the July 2007 match, ambient temperature was recorded as 36 ± 0 ⁰C with a relative humidity of 61 ± 1 %. Peak Tc values recorded for June and July matches were 39.1 ± 0.4 ⁰C, and 39.6 ± 0.3 ⁰C respectively. Total distance covered during June and July matches was 8.6 ± 0.6 and 8.1 ± 0.7 km respectively. The total distance covered in the first and second halves were: 4.4 ± 0.4 and 4.2 ± 0.3 km for June and 4.3 ± 0.5 and 3.8 ± 0.4 km for July matches. The difference between the halves of the July match was significant. The running distance covered in the second half of the July match was significantly shorter than first half of July and second half of June matches (2.1 ± 0.4 and 1.9 ± 0.3 km for the first and second halves of June and 1.9 ± 0.5 and 1.3 ± 0.4 km for the first and second halves of July matches;$p<0.05$)
Conclusion: In soccer matches played in high environmental temperature and humidity, the physical performance of the players may decrease due to high thermal stress. In the present study, the players' increased body core temperature at half time was followed by a decrease in total distance covered in the second half of the game. This may point to a centrally-driven performance reduction.

COOLING INTERVENTION AND SOCCER UNDER EXTREME HEAT CONDITIONS

KURDAK, S.S., ÖZGÜNEN, K.T., MAUGHAN, R., ZEREN, Ç., KORKMAZ, S., YAZICI, Z., ERSÖZ, G., SHIRREFFS, S., DVORAK, J., BINNET, M.S.
1. ÇUKUROVA UNIVERSITY, TURKEY, 2. LOUGHBOROUGH UNIVERSITY, UNITED KINGDOM, 3. ANKARA UNIVERSITY, TURKEY, 4. FIFA/FMARC, SWITZERLAND

Whole body pre-cooling with fluid ingestion had been discusses as one of the main interventions to improve athletic performance in extreme heat conditions. Extensive research had been performed to evaluate the effect of precooling on athletic performance and body core temperature, but the influence on a soccer match had not been investigated. Purpose: The aim of this study was to investigate the effect of cooling intervention on athletic performance and body core temperature during a competitive soccer game. Methods: 11 soccer players aged 21 ± 2 y (mean ± SD) with V'O2max of 59.8 ± 5.0 ml/kg/min volunteered to play two matches (without – C and with cooling intervention-CI) for this study. The ambient temperature and humidity was 34.3 ± 0.6 oC and 64 ± 2 % for the first and 34.0 ± 0.5⁰C and 62 ± 0 % for the second game (CI) respectively. Players had opportunity to consume ad libitum plain water during the C, plain water or sports drink by choice during CI study. A cooling tent and icy water filled buckets placed beside the soccer field were used for cooling intervention. Match activity was recorded by a global positioning system. Thermosensor pills were used for body core temperature (Tc) measurements. Blood samples were withdrawn from an antecubiteal vein 5 hours before and immediately after the game to determine hematocrit (Htc), hemoglobin content (Hb), calculate plasma volume loss, and changes of serum electrolytes. ANOVA and paired sample t-test was used to evaluate the level of significance, and p values < 0.05 were accepted as significant. . Results: The highest Tc value recorded during the last ten minutes of the first half and the difference between C and CI groups was not significant (39.54 ± 0.5 vs 39.3 ± 0.5oC respectively). Total liquid consumption was measured as 1473±422 ml for C, and 1230±494 ml for CI group (926±604 ml plain water, and 304±240 ml sports drink). Post-match dehydration % was similar for both C (2.49±0.67) and CI match (2.54±1.21). Pre- and post-match Htc (48.9±3.3 vs 49.2±3.3 %) and Hb (161±14 vs 163±13 g/L) were used to calculate % plasma volume change (0.1±5.5 %) for the C match. The plasma volume loss for the CI group was calculated as -5.1±5.6 with pre- and post-match Htc (46.2±2.3 vs 46.9±2.1) and Hb (153±10 vs 156±9) content. Plasma volume loss for C and CI groups were not significant. Pre- and post-match difference of serum Na (145±2.5 vs 144±3 mmol/L), and K (5.4±0.4 vs 5.4±0.4 mmol/L) for C and CI groups were not significant. CI did not change distance covered during the game significantly (8298 ± 589 meters vs 8315±549 meters for C and CI groups respectively)
Conclusion: Cooling intervention was not sufficient to reduce Tc and improve match performance significantly. Slight reduction of Tc that observed with whole body cooling, may be important for prevention of heath related problems that occur in extreme heat conditions.

PLAYING FOOTBALL <SOCCER> UNDER EXTREME HEAT CONDITIONS – EFFECT OF ACCLIMATISATION

ERSÖZ, G., KURDAK, S.S.., ÖZGÜNEN, K.T., MAUGHAN, R.J.., ZEREN, C., KORKMAZ, S., YAZICI, Z., BINNET, M.S.
1. ANKARA UNIVERSITY, 2. ÇUKUROVA UNIVERSITY, 3. LOUGHBOROUGH UNIVERSITY

Exercise intensity is an important factor to induce thermal strain, and soccer is a challenge for the players who have to play under extreme heat conditions. Acclimation is an important intervention to improve thermal tolerance and endurance capacity.
Purpose: We aimed to evaluate effect of acclimation on sportive performance during a game played under extreme heat conditions
Methods: 11 male acclimated soccer players (age 23  2 y, VO2 max 61.8  1.1 ml.min-1.kg-1) and 10 unaccli-

mated male soccer players (age 21  1 y, VO2 max 62.3  1.5 ml.min-1.kg-1) volunteered to participate in this study. Acclimated (A) and unacclimated (UA) teams played separately against a high level competitive local team at the second half of July 2007. Acclimated players played with an ambient temperature and humidity of 35.6  0.3 oC and 46  2 % respectively. Temperature and humidity was recorded as 36.00.2 oC and 61  1 % during the UA match. Match activity was recorded by a global positioning system. Thermosensor pills were used for body core temperature (Tc) measurements. Blood samples taken 4 hours before and immediately after the game to determine hematocrit (Htc), hemoglobin content (Hb), calculate plasma volume loss, and changes of serum electrolytes. Urine analyses performed before the game. ANOVA and paired sample t-test was used to evaluate the level of significance, and p values < 0.05 were accepted as significant. . Results: The highest Tc value recorded during the last ten minutes of the first half and the difference between A and UA groups was not significant (39.0  0.3 vs 39.51  0.3oC respectively). Urine specific gravity value of A players (10206) was significantly lower than UA players (10277) (p < 0.05). Pre- and post-match Htc (43.5  3.3 vs 46.1  2.5 %) and Hb values (153  11 vs 154  12 g/L) were used to calculate % plasma volume change (-4.38.13 %) for the A players. The plasma volume loss for the UA players was calculated as -4.82.8 % with pre- and post-mach Htc (45.8  2.6 vs 47.0  1.3) and Hb (161  7 vs 166  9; p<0.05) content. Difference of plasma volume loss for A and UA football players was not significant. Post-match serum Na (1412 vs 1424 mmol/L), K (4.30.3 vs 4.60.4 mmol/L) for A and UA players were not significantly different from each other. The difference of total distance covered by A (8514  630 m) and UA (8154  731) players were not significant. Average distance covered by A players during the second half of the game was significantly higher then the UA players (4156  354 vs 3761  358 m respectively; p<0.05). Conclusion: Playing football in extreme heat conditions is an important challenge for adjustment of thermal balance. Increased body temperature together with dehydration may reduce exercise capacity. Acclimatisation is an important intervention to reduce heat strain. The increased sportive performance may be interpreted as another beneficial effect of acclimatisation.

HORMONAL AND NEUROENDOCRINE RESPONSES AND TRAINING ADAPTATIONS FOLLOWING 8-WEEKS OF PRE-SEASONAL PREPARATION PERIOD IN YOUNG HIGH-LEVEL SOCCER PLAYERS

HADJICHARALAMBOUS, M.

UNIVERSITY OF NICOSIA

Introduction: Various hormonal responses to training-stress are measured for examining training adaptations particularly in adults' athletes. However, little information is available regarding hormonal and neuroendocrine responses to intense pre-seasonal preparation training in young athletes, in particular in youth soccer-players. The purpose therefore of the present study was to examine neuroendocrine and selected hormonal responses and their association with physiological adaptations to 8-weeks of pre-seasonal preparation training in young high-level male soccer-players.

Methods

All anthropometric measurements, physical fitness components and neuroendocrine and hormonal responses of eighteen (n = 18) well-trained players were evaluated in three occasions: at base-line, immediately prior to the initiation of preparation period (pre-conditioning) and 48-hours following the completion of the 8-weeks' training program (post-conditioning).

Results: Total IGF-1, growth hormone (GH), plasma testosterone (T) and cortisol (C) and T:C ratio were not different between assessments but plasma prolactin (Prl) (p = 0.001) was significantly lower at post-training period. Body weight (p = 0.349), BMI (p = 0.266), resting systolic (p = 0.230) and diastolic (p = 0.527) blood pressure and sit and reach flexibility (p = 0.61) were not different among measures but HRmax (p = 0.014) was significantly lower at post-conditioning evaluation. Body fat percentage (%) (p = 0.0005) was lower and aerobic capacity (p = 0.0005), leg explosiveness (p = 0.0005), and muscular endurance [1 min-sit-ups (p = 0.001) and 1 min-push-ups (p = 0.029)] were improved by the end of preparation period. There was a significant negative correlation between endurance capacity and resting plasma Prl levels. No correlation was observed between plasma IGF-1, GH, T, C and the other fitness components, which all were examined separately.

Discussion: The present study suggests that although the overload pre-seasonal training program improved soccer-specific fitness components of young high-level soccer players, several selected hormonal responses (e.g. total IGF-1, GH, plasma T and C and T:C ratio) were not influenced by the pre-seasonal training program with the exception of the reduction in resting plasma Prl concentration. Consequently, this response may reflect an increase in brain serotonergic system adaptations and/or tolerance to intense soccer pre-seasonal training. The present study provides preliminary evidence for using resting levels of plasma Prl as an indicator for training adaptations to pre-seasonal preparation period in young sub-elite soccer players.

AGE-RELATED DEVELOPMENT OF BIOLOGICAL - AND PERFORMANCE INDICES OF AUSTRIAN SOCCER PLAYERS

GUSCHELBAUER, R., OBERHAMMER, O., TSCHAN, H.

FACULTY OF SPORT SCIENCE, UNIVERSITY VIENNA

Introduction: Soccer is characterized by numerous sprint bursts interspersed by brief recovery periods over an extended period of time (60-90 minutes) activating both, the aerobic and the anaerobic energy systems. This study was intended to examine the age-related development of aerobic endurance and sprint velocity of seven age-related sub-groups of adolescent soccer players ranging from 7-18 yrs in comparison to elite players of the Senior League.

Methods: The sample included 105 soccer players (at least 11 players were tested in every sub-group). Biological development of height, body mass and body mass index were measured and two tests of functional capacity: Aerobic fitness 20-m multistage shuttle run (20 SRT) and sprint running abilities (sub-intervals and total time of a 30 m dash measured electronically) were administered. Estimated relative maximum of oxygen uptake (rel. VO2max) was predicted from age and maximum speed of the 20 SRT.

Results: Anthropometric data, sprint abilities and endurance performance improved continuously with increasing age. However, the performance improvement in speed and endurance capabilities was only significant in teams having an age difference of 3 and more years. The only exception in this respect was detected is between the players being 14 yrs old and those being 16 yrs old were a significant gap in performance indices existed probably due to the growth spurt. It is remarkable however, that there are no significant differences between the teams of the under 16 – and under18 year old soccer players, and players of the male elite team in aerobic performance measures and sprint abilities. Surprisingly there was a highly significant correlation between endurance performance and quickness of the tested players leading to the result that those players who had higher developed aerobic endurance performance also were the fastest players.

Conclusion
The biological maturity status significantly influences the functional capacity and athletic performance (speed and aerobic endurance) and highlights the inter-relationship of growth, maturity and functional characteristics of youth soccer players. The lack of further improvements in aerobic endurance capacity and sprint abilities of soccer players being 16 yrs and older detected in this study underlines the importance of continuing and improving the proportion of athletic training in adult soccer players.

HIGH INTENSITY SHOCK MICROCYCLES: AN EFFICIENT METHOD FOR IMPROVING VO2MAX IN JUNIOR ALPINE SKIERS

BREIL, F.A., WEBER, S.N., KOLLER, S., HOPPELER, H., VOGT, M.

1 INSTITUTE OF ANATOMY, UNIVERSITY OF BERN, SWITZERLAND, 2 INSTITUTE OF HUMAN MOVEMENT SCIENCES AND SPORT, SWISS FEDERAL INSTITUTE OF TECHNOLOGY ZURICH, SWITZERLAND, 3 INSTITUTE OF SPORT AND SPORT SCI

Introduction: Maximal oxygen consumption (VO2max) is often used to predict aerobic endurance capacity. In already-trained soccer players, VO2max can be further improved by performing high-intensity interval training (HIT) sessions twice a week over two months (Helgerud et al., 2001). Alternatively, it seems that VO2max can effectively be increased when HIT sessions are performed once or twice daily within a condensed 10-day shock microcycle (Stolen et al., 2005). Such a concept could be particularly useful for athletes who cannot afford the time for extensive endurance training due to high technical and strength demands of their sport. The aim of our study was to investigate the effect of an 11-day high-intensity shock microcycle on endurance and jump performance in junior alpine skiers.

Methods: Six female and sixteen male subjects (age: 17.0 ± 1.1 yr, body mass: 67.3 ± 10.4 kg) were matched and randomly assigned to either a high-intensity interval training group (HIT, N = 13) or a control training group (CON, N = 8). HIT performed 15 HIT-sessions (12 on a cycle ergometer, 3 on an obstacle course) during 11 days. Each session consisted of 4×4 min at 90-95% of the individual maximal heart rate (HRmax), separated by 3-min recovery periods. CON continued their normal mixed training including endurance and strength sessions. Before, 24 hours and seven days after the training period, anthropometric data were gathered and ramp tests to exhaustion on a cycle ergometer were performed to determine HRmax, VO2max, peak power output (PPO) and the first and second ventilatory thresholds (VT1, VT2). At the same time-points, countermovement and squat jumps were performed on a force plate.

Results and discussion: Body mass and fat-free mass were reduced in HIT only (-1.0%,-1.1% ($P < 0.05$), respectively). Seven days post-intervention HIT significantly improved VO2max by 6.0% (pre: 53.0 ± 4.6, post: 56.2 ± 5.1 mL•kg-1•min-1; $P < 0.01$) and PPO by 4.4% (pre: 5.2 ± 0.4, post: 5.5 ± 0.5 W•kg-1; $P < 0.01$). CON showed slight but nonsignificant improvements in VO2max (+3.0%) and PPO (+2.0%). Power output at VT2 increased in HIT by 9.6% ($P < 0.01$), but not in CON, whereas jump height was unchanged in both groups. In the HIT-group the described functional improvements were already present but to a lesser extent in the post 24-hours measurements.

Our results show that high-intensity interval block training might be a very time efficient way to improve VO2max, PPO, and the power output at VT2 in junior alpine skiers. Accumulated fatigue of such an intense training cycle seems to delay the development of the functional adaptations. Therefore, athletes and coaches should plan rest-days to ensure adequate recovery and maximal training effect.

ACTIVE OR PASSIVE - THE INFLUENCE OF TWO DIFFERENT REST PROTOCOLS ON POWER OUTPUT, LACTATE AND PH TIME COURSE AND PEAK OXYGEN UPTAKE DURING HIGH INTENSITY TRAINING <HIT>

HAEGELE, M., ZINNER, C., WAHL, P., SPERLICH, B., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: During past years much scientific effort has been undertaken to observe the effects of high intensity training (HIT) on endurance performance. Although many studies used varying intensities during the exercise bouts, much less data exists describing how the recovery periods between the intense bouts should be realized. To answer this question, the role of lactate and hence pH has to be considered, since the accumulating lactate during passive recovery is still often considered as major parameter causing muscle fatigue. Latest scientific research reports by contrast that lactate acts as energy reservoir and signal molecule. Due to these findings, the aim of this study was to compare the effects of two different rest protocols power output and physiological parameters.

Methods: 12 male endurance athletes (age: 24,4 ± 3,9 years, height: 183,9 ± 4,6 cm, weight: 76,2 ± 7,2 kg) completed two testing sessions on a cycle ergometer. Each testing session consisted of a 10min warm up at 2 Watt/kg followed by four 30sec maximal sprints. The 10min recovery periods between the sprints were either active (ACT, cycling at 1,5 Watt/kg) or completely passive (PAS), which was assigned randomly. Peak Power (PP) and Mean Power (MP) were detected for each sprint. During the recovery intervals capillary blood was used to detect lactate concentrations (Lac) at 0, 1, 3, 5, 7 and 9min. Furthermore pH was measured at 2, 6 and 9min, whereas oxygen uptake (V02peak) was observed during the whole training session.

Results: MP was 749 ± 120, 741 ± 122, 720 ± 120 and 709 ± 108 Watt for ACT and 740 ± 109, 712 ± 91, 660 ± 90 and 653 ± 93 Watt for PAS. The difference between the two recovery protocols reached statistical significance at the 3rd & 4th bout. Lac were similar 0, 1, 3 and 5min after the first bout but the concentrations in ACT decreased significantly from 7min and remained lower for all following points of measurement. pH differed significantly from 9min after the second bout, showing higher values for ACT. Analysis of spirometric data revealed no statistical difference for VO2peak during the bouts.

Conclusion: Our study revealed that the active recovery protocol was more sufficient to sustain power output over four consecutive maximal bouts. Furthermore it can be speculated if an active recovery process allows an athlete to perform more intense intervals in a row. Anyhow, dependent on the aim of a training intervention one should consider possible differences in metabolic stimuli due to different recovery protocols and resulting lactate concentrations as well as acid-base balances. Several studies provide evidence for an impact of acidosis and lactate on growth hormones and transcription factors which would favor passive recovery protocols due to greater physio-

logical stimuli. To assess these stimuli and characterize subsequent adaptations, not only the character of exercise but also recovery should be considered when developing new training strategies.

HIGH INTENSITY PHYSICAL ACTIVITY CORRELATES WITH IMPROVEMENT IN VASCULAR FUNCTION IN 9-11 YEAR OLDS.

HOPKINS, N., STRATTON, G., TINKEN, T.M., MCWHANNELL, N., RIDGERS, N., GRAVES, L.E.F.

LIVERPOOL JOHN MOORES UNIVERSITY

Background. The prevalence of obesity and physical inactivity in Western countries has increased in recent years. Both are modifiable risk factors for cardiovascular disease. Endothelial dysfunction has its origins in childhood and plays a fundamental role in the development of the atherosclerotic disease process. However little is known about the factors which modify endothelial function in children. The present study therefore aimed to examine the relationships between change in artery health and its predictors in children.

Methods This was an observational cohort study. We studied 116 nine-eleven year old children (70 female, 46 male). Flow mediated dilation (FMD), an index of vascular health, was assessed in the brachial artery and normalised for differences in its eliciting shear rate stimulus (FMD/SRAUC). Body composition was assessed by dual energy X-ray absorptiometry (DXA) and peak VO2 determined on a treadmill ergometer. Physical activity (PA) was assessed over 5 second epochs using uniaxial accelerometry across a 7 day period. All measurements were taken at baseline and repeated 16 weeks later, in order to assess whether changes in the above variables impacted upon FMD. Change scores were calculated, correlations performed and stepwise backwards linear regression used to identify predictors of change in FMD.

Results No sex differences existed so data was pooled. Change in FMD/SRAUC was correlated with change in high intensity PA (r=0.3, p=0.002), change in average counts per minute (r=0.25, p=0.009) and change daily steps (p=0.202, r=0.034). Regression analysis revealed that change in high intensity PA was the only predictor of change FMD/SRAUC (r2=0.126, p=0.001).

Conclusions FMD was not significantly related to changes in body composition, cardiorespiratory fitness levels or low to moderate intensity PA. The significant association between change in FMD and change in high intensity physical activity suggests that future interventions should focus on encouraging this form of behaviour.

AEROBIC INTERVAL TRAINING VERSUS STRENGTH TRAINING AS A TREATMENT FOR THE METABOLIC SYNDROME

STENSVOLD, D., TJØNNA, A.E., SKAUG, E.A., WISLØFF, U., SLØRDAHL, S.A.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

Background: Physical inactivity and overweight is strongly associated with an increased risk for developing metabolic syndrome. The syndrome is characterized by a clustering of risk factors related to cardiovascular disease and mortality such as increased blood pressure, impaired glycemic control, excess of abdominal fat and dyslipidemia. Regular physical activity followed by increased fitness can improve the metabolic profile and reduce the risk of developing cardiovascular diseases, however the optimal training regime for reversing metabolic syndrome and its associated cardiovascular abnormalities remain undefined.

Methods: Forty subjects were randomized (stratified by gender and age) to either aerobic interval training (AIT, n=11), strength training (ST, n=10), combination of aerobic interval training and strength training (COM, n=9), or a control group (n=10). Training was performed 3 times per week for 12 weeks, and risk factors comprising the metabolic syndrome were measured before and after the intervention in all four groups.

Results: AIT and COM significantly increased VO2peak (34.2 ± 9.8 to 38.6 ± 11.3 ml•kg-1•min-1 for AIT and 28.4 ± 6.3 to 31.5 ± 10.2 ml•kg-1•min-1 for COM). Maximal strength was significantly increased after COM (EMM 1.8 kg•lbm-0.67, 95% CI, 0.935-2.626) ST (EMM 3.1 kg•lbm-0.67, 95% CI, 2.456-3.765) as well as in the control group (EMM 0.7 kg•lbm-0.67, 95% CI, -0.08-1.431). AIT significantly reduced triglyceride levels (from 2.27 ± 0.97 to 1.83 ± 0.76 mmol/l) systolic blood pressure (from 140 ± 14.6 134.2 ± 12 mmHg) and diastolic blood pressure (from 89 ± 8.1 to 85 ± 5.5 mmHg). Only ST reduced waist circumference significantly (from 111.5 ± 10.8 to 110 ± 11 cm). Endothelial function measured as flow mediated dilatation (FMD) was significantly improved in all three training groups (AIT 7.1 ± 2 to 8.8 ± 2.8, COM 7.2 ± 2 to 9.1 ± 2.4 and ST 8.1 ± 3.1 to 11 ± 4.7). No change occurred in weight, fasting plasma glucose, high density lipoprotein or insulin C-peptide in either group.

Conclusion: Although all three training regimes improved abnormalities associated with the metabolic syndrome, 12 weeks of AIT was superior to both strength training and a combination of interval and strength training for improving risk factors related to the metabolic syndrome. Three out of the six risk factors identifying the metabolic syndrome were significantly improved after 12 weeks of aerobic interval training.

EFFECTS OF DIFFERENT WARM UP INTENSITIES ON LACTATE DISTRIBUTION IN DIFFERENT BLOOD COMPARTMENTS AND POWER OUTPUT

WAHL, P., ZINNER, C., HAEGELE, M., BLOCH, W., MESTER, J.

GERMAN SPORT UNIVERSITY

Introduction: An improved lactate transport across the red blood cell membrane might be an advantage during high intensity exercise by increasing the muscle-to-plasma [La] gradient and therefore allowing more lactate/H+ to leave the muscle. It is hypothised that the bioavailability of MCT (Monocarboxylattransporter) may be altered by translocation from cytoplasm to the membrane of RBC when it is needed. Therefore we investigated if lactate transport across RBC membrane can functionally be influenced after maximal exercise by previous different warming up protocols (WU).

Methods: At three subsequent visits to the laboratory, subjects performed 30 s lasting maximal sprint tests on a cycle ergometer with different prior warm up intensities: 1. without prior warming up (W), 2. extensive warm up (E): 12 min cycling at 60% of VO2 peak, 3. intensive warm up (I): 12 min cycling at 60% of VO2 peak including three 10 s lasting peaks at 200% of VO2 peak. After warming up, subjects stayed in a sedentary position for 5 min followed by the maximal sprint test. Blood samples were taken under resting conditions, after warming up, before sprint exercise (pre M) and in minute intervals during recovery (0 min-15 min) to determine lactate concentrations in whole blood, plasma and RBC.

Results: The initial increments (pre M-0') in plasma & RBC [La] showed significant differences between W/E and I. The RBC/plasma [La] ratio of the increments (pre M-0') was significantly lower for I (0.23 ± 0.06) compared to W & E (W: 0.28 ± 0.04 & E: 0.27 ± 0.04). These

differences were due to lower increments in RBC [La] (-16% W vs. I & -10% E vs. I). No significant differences were found for the increments of plasma, RBC & ratio in the following time intervals.

The peak power (PP) output as well as the mean power (MP) output for the sprint test was significantly lower for W (MP: 680 ± 181 Watt) compared to E & I (MP: 738 ± 192 Watt; E) (MP: 740 ± 191 Watt; I).

Discussion: Several possible effects of WU are discussed in literature which might have an effect on performance. In the present study we tested if different warming up intensities influence the lactate flux across the RBC membrane. A recent study from our group has shown that MCT in RBC might be translocated from cytoplasm to the membrane in response to exercise, which might effect La flux. In the present study the WU had no influence on La flux across the RBC membrane. The increase in plasma [La] was significantly lower in the first time interval for "I". Therefore one would expect a similar or even higher increase in RBC [La] (and not a lower) because of a less stressed transport system. But may be it must be considered, that the pre-loading of RBC with lactate and therefore the [La] gradient is different between the conditions. It can be speculated, that the time (of warming up) was too short to induce a translocation of MCT. Further molecular investigations are needed to identify possible mechanisms for translocation of MCT.

THE EFFECTS OF 15-WEEKS HOCKEY SPECIFIC TRAINING ON SKELETAL HEALTH AND BODY COMPOSITION IN ACTIVE WOMEN

WALLACE, J.A., REILLY, T., GEORGE, K.

ABERYSTWYTH UNIVERSITY

Introduction: The importance of sport and exercise for optimizing body composition and bone health in women is well documented (Drinkwater et al., 1995). Although evidence from former athletes suggests that any training-induced anabolic skeletal effect achieved, disappears after the cessation of an athletic career (Karlsson et al., 2000 and 1996). There is a lack of information about bone health in relation to seasonal changes in training and the overall long-term health benefits in active women. The aim of this investigative study was to establish whether 15 weeks of hockey-specific training and match-play had a beneficial effect on bone mineral density and body composition in active pre-menopausal women.

Method: Body composition (total mass, fat mass, lean mass, and percent body fat) and whole-body, proximal femur and lumbar spine bone mineral density (BMD), of 12 female club-level hockey players (32.8 ± 7.8 years; 58.7 ± 5.0 kg; 1.64 ± 0.04 m) and 13 normo-active controls (32.9 ± 7.1 years; 59.3 ±6.6 kg; 1.63 ± 0.05 m), were measured using dual-energy X-ray absorptiometry (DXA). Measures were taken pre-season and before the mid-season break, 15-weeks apart. Training consisted of 2.5 hours of hockey-specific fitness work, plyometrics, drills and practices and a 70-minute match each week, in addition to their normal physical activity. Data were analysed using SPSS v14, by means of a 2-way mixed model design ANOVA.

Results: The hockey players had significantly greater ($P < 0.05$) proximal femur BMD (trochanter and inter-trochanter) at baseline compared to the controls; all other body composition variables were not significantly different. After 15 weeks of training the hockey players had a significantly lower percent body fat ($P < 0.05$) and significantly greater lumbar spine BMD (L1, L2, L3 and L4) and proximal femur BMD (neck, trocahanter and intertrochanter) than the normo-active control group. The hockey players exercise duration, also significantly increased during season (from 3.6 ± 2.3 pre-season to 6.2 ± 2.2 hours/week mid-season; $P < 0.05$).

Discussion: Long-term participation in hockey can improve body composition and enhance BMD at the lumbar spine and proximal femur, by means of increasing bone mass accrual. The hockey players had 18.3 ± 8.4 years playing experience, during which sport specific skeletal adaptions should have occurred. However, some skeletal regions (i.e. lumbar spine) still increased in BMD during the season, demonstrating that these sites may be susceptible to transient changes in BMD due to the seasonal nature of the sport. Therefore off-season exercise needs to be promoted, to help maintain long-term bone health in team sports.

THE EFFECT OF INCREASED VOLUNTARY EFFORT ON NEUROMUSCULAR CONTROL IN HIGH IMPACT LANDING

The effect of increased voluntary effort on neuromuscular control in high impact landing

Leg extensor muscles have been shown to be activated well before the onset of ground contact during natural movements like running, jumping, landing etc. In landing tasks the motor system has to adjust pre-landing activity based on the predicted impact peak in order to achieve a safe and smooth landing (Santello 2005). Furthermore, it has been shown that in the case of very high impact loads the post-impact response is crucial as it modifies body acceleration (Melvill Jones and Watt 1971). However, the exact mechanism that modulates electromyographic (EMG) activity in the early post-impact phase is unclear. Both pre-programmed (Melvill Jones and Watt 1971) and reflex (Santello and McDonagh 1998) origins have been suggested. Therefore, the purpose of the present experiment was to study the contribution of spinal and supraspinal mechanisms during extreme landing conditions, where pre-contact activities of the leg extensor muscles could be voluntarily varied.

Eight healthy young male subjects participated in the experiment. They performed ten drop jumps on a sledge ergometer with free pre-activity (FREE) and ten with pre-activity corresponding to 60% of isometric maximal voluntary contraction (60%MVC). For this purpose a special ankle support was designed and used, where subjects could induce different levels of isometric contractions during the landing. Dropping height corresponded to 200% of the maximal squat jumping height. Transcranial magnetic stimulation (TMS) over the motor cortex and peripheral nerve stimulation over the tibialis nerve were induced during the early post-impact phase (on average 17ms after the impact). Motor evoked (MEP) and H-reflex responses were recorded from the soleus muscle. Stability of the TMS coil was verified with three dimensional motion analyses.

Interestingly, our data suggest that the increased pre-contact activity of the plantar flexor muscles prior to ground contact does not modify the neural strategy during the early post-impact phase. There were no differences in MEP and H-reflex peak-to-peak amplitudes or in their ratios between the FREE (approx. 20%MVC) and 60%MVC conditions. It would be logical to suggest that the increased voluntary activity was not able to counteract the inhibitory effects probably originating from Golgi tendon organs. However, high and unaffected SLR reflex amplitudes invalidate this suggestion. Since there were similarities in the EMG patterns towards the impact, it could be suggested that increased voluntary effort was not able to bypass the effect of the pre-programmed landing strategy.

PROLONGED WALKING INCREASES COMPLIANCE IN THE HUMAN SOLEUS MUSCLE-TENDON UNIT: IMPLICATIONS FOR THE SHORT LATENCY STRETCH REFLEX

CRONIN, N.J., ISHIKAWA, M., AF KLINT, R., KOMI, P.V., AVELA, J., SINKJAER, T., VOIGT, M.

AALBORG UNIVERSITY, DENMARK; UNIVERSITY OF JYVÄSKYLÄ, FINLAND

After repeated passive stretching, tendinous tissue compliance increases in the human soleus muscle-tendon unit (1,2). If present in dynamic conditions, this would influence force transfer between muscle fibres, tendons and bones, and could decrease the stretch stimulus to the spindles, thus influencing stretch reflex responses. The existence of such changes in locomotion is yet to be investigated.

Eleven healthy subjects walked on a treadmill at a gradient of 3% for approximately 60 minutes with the left leg attached to a robotic actuator capable of rapidly dorsiflexing the ankle joint (3). Ultrasound was used to measure soleus fascicle lengths and surface EMG activity was recorded. Stretch reflexes were elicited by applying 6° (250°/s) stretches at three time intervals; Pre (immediately before the walking intervention), Mid (after approximately 30 minutes of walking) and Post (immediately after the intervention). If the intervention did cause an increase in tendinous tissue compliance, it was anticipated that stretch reflex amplitudes would be lower at the end of the protocol. As muscle spindle Ia afferents are velocity sensitive, an additional series of faster stretches (approximately 270°/s) were performed at the Post interval.

Between the Pre and Post intervals, the amplitude and velocity of fascicle stretch decreased (by 46% and 59%, respectively) in response to a constant external stretch, as did stretch reflex amplitudes (33%). A faster stretch elicited at the end of the protocol resulted in a recovery of fascicle stretch velocities and reflex amplitudes to approximately the pre-exercise values. These findings, in addition to a lack of change in electrically evoked muscle twitch properties, support the theory that repeated stretching and shortening of a muscle-tendon unit can induce structural changes in the tendinous tissues (1), and provide evidence for the existence of this phenomenon during low intensity human locomotion. As muscle spindles are mostly velocity- and length-sensitive receptors, any reduction in fascicle stretch velocity and amplitude due to changes in tendinous tissue compliance could reduce muscle spindle afferent feedback, and thus decrease the amplitude of the resulting stretch reflex response. The increase in tendinous tissue compliance may also compromise the efficacy of storage and reutilization of elastic energy in the tendinous tissues.

SHORT-TERM PRESSURE INDUCED SUPPRESSION OF THE SHORT LATENCY RESPONSE – A NEW METHODOLOGY FOR INVESTIGATING FUNCTIONAL STRETCH REFLEXES

LEUKEL, C., TAUBE, W., LUNDBYE-JENSEN, J., GOLLHOFER, A.

UNIVERSITY OF FREIBURG; UNIVERSITY HOSPITAL BALGRIST, ZÜRICH; UNIVERSITY OF COPENHAGEN

Peripheral afferent feedback during movement is used not only for controlling the actual performance but also to drive the α-motoneurons and thereby enhance the motor output. Especially stretch-shortening cycle contractions provide an experimental model in which afferent feedback is used as the latter: the short-latency response (SLR) of the spinal stretch reflex has been argued to enhance tendomuscular stiffness and thereby enable elastic energy to be stored during the eccentric phase of the contraction (Komi & Gollhofer, 1997). To investigate functional stretch reflexes, many studies applied an ischemic nerve block to annihilate the SLR (e.g. Grey et al., 2001). However, ischemia is accompanied with several methodological drawbacks, including the associated pain and therefore the restricted movement behaviour as well as the short time window allowed for investigation, which limit its application in highly functional tasks. Here, we present a new methodology to investigate functional stretch reflexes possessing none of the abovementioned limitations.

10 healthy subjects (age 27±2 years) participated in this study. A conventional blood pressure cuff was used to apply short-term pressure to the right calf muscles by inflating the cuff to 220 – 240 mmHg immediately (10 seconds) before the measurement started. EMG recordings were obtained from m. soleus of the right leg. Subjects were asked to perform hopping movements at a submaximal intensity. 40 hops were averaged with the cuff deflated and inflated in a randomized order.

Inflation of the pneumatic cuff decreased the size of the SLR in m. soleus during hopping in 7 out of 10 subjects (cuff deflated: 0.67±0.32 mV versus cuff inflated: 0.55±0.32 mV). The three remaining subjects showed no difference in the size of the SLR between deflated and inflated cuff.

The present study showed that short-term pneumatic pressure is able to reduce the SLR during hopping. Based on additional protocols not mentioned in this abstract it is argued that - with inflated cuff – the induced stretch is mechanically modulated. It is concluded that this mechanical modulation of the stretch is suitable to investigate functional stretch reflexes during highly dynamic tasks.

MAXIMAL AMPLITUDE OF THE M-WAVE IN SOLEUS MUSCLE DURING STANDING IN WATER

TAKAHARA, T., SEKI, K., YAMAGUCHI, H., ONODERA, S.

GRADUATE SCHOOL, KAWASAKI UNIVERSITY OF MEDICAL WELFARE

INTRODUCTION: The M-wave is compound muscle action potentials lead to stimulation of motor axons in peripheral nerves. Maximal amplitude of the M-wave (Mmax) indicates that all α-motor fibers were recruited. Amplitude of the M-wave is also used as the stationary of the electrical stimulus. Previously, it was considered that the M-wave did not influenced by the central nerves system. Recent study reported that Mmax in soleus muscle (SOL) changed with the ankle joint angle. This result suggests that amplitude of the M-wave may change with condition even though the stimulus intensity is constant. In water, human is affected by the physical characteristics of water and different physiological responses are showed relative to land. The electromyographic (EMG) activity in SOL during standing, walking and running in water differed from that on land. Therefore we speculated that Mmax in SOL during standing changes with somatosensory inputs for lower legs. The purpose of this study was to investigate the effects of decreasing the body weight induced by the buoyancy to Mmax in SOL during stationary standing. METHOD: Six healthy males participated in this study. Subjects stood on a waterproof force platform. Subjects were tested under two randomly administered conditions; (1) standing on land and (2) standing in water. The experiments in water were performed in a water tank. The depth of water inside the tank was adjusted on the gastrocnemius muscle belly of each subject. The temperature of water was kept constant at 34 ℃. M responses were elicited in SOL during standing each condition by electrical stimulation with single square pulse of 1ms duration to the tibial nerve in the popliteal fossa. Surface EMG was recorded from SOL using bipolar electrodes. The electrodes were covered with water resistant adhesive microfilms. Mmax was defined peak to peak amplitude of M-wave at the time of the disappearance of the H-wave associated with the increasing of stimulus intensity. RESULT AND DISCUSSION: The average of ground reaction force (GRF) during standing in water was significantly lower ($P<0.05$) than on land. The average Mmax during standing in water was significantly lower ($P<0.05$) than on land. It was considered that approximately 10 % decrease of the average GRF was caused by the buoyancy. Postural control of human performed to adjust the activity of the anti-gravity muscles reflexively and voluntarily by receiving from visual, vestibular and somatosensory systems. Motoneuron pool of the anti-gravity muscles is affected the somatosensory inputs from the skin, the joint, the muscle spindle and the tendon spindle. From these factors, it is suggested that the decreasing of Mmax is the appropriate response of body related to changes in somatosensory inputs. In conclusion, Mmax in SOL shows the gravitational information for body to vertical direction.

RELIABILITY AND GENERALIZABILITY OF CONSECUTIVE MAXIMUM CONTRACTIONS AS A TEST OF NEUROMUSCULAR FUNCTION

NEDELJKOVIC, A., SUZOVIC, D., JARIC, S.

UNIVERSITY OF BELGRADE (BELGRADE, SERBIA), UNIVERSITY OF DELAWARE (NEWARK, USA)

Introduction: The standard strength tests (SST), based on sustained maximum isometric and isotonic contractions of relevant muscle groups, have been widely used to assess neuromuscular function. However, numerous functional movements are based on either short-lasting muscle actions or consecutive actions of antagonistic muscle groups (e.g., postural corrections, walking, running, throwing, kicking). Therefore, SST may not capture the neural activation typical for a number of important natural movement patterns. We recently conducted a preliminary evaluation of a novel test of neuromuscular function based on consecutive maximum contractions (CMC; Suzovic et al., 2008). The aim of this study was to evaluate the reliability of CMC as well as to generalize previous findings across different muscle groups.

Methods

Male physically active participants (N=12) performed three consecutive trials of SST of quadriceps muscle, as well as the paced isometric CMC (i.e., a series of consecutive maximum force exertions and relaxations). Following the initial session, two subsequent trials were performed after two days and six weeks, respectively. In addition, thirty six subjects performed the same two tests of four different muscles (i.e., knee flexor and extensor, and elbow flexor and extensor muscle). SST provided the maximum voluntary force and the rate of force development, while CMC (exerted at self-selected frequency) revealed the peak force, and the rates of force development and relaxation. Intraclass correlation coefficients (ICC) and coefficients of variations (%CV) were used to assess the reliability, while a principal component analysis was employed to assess the relationships among the dependent variables obtained from different muscle groups.

Results: The evaluated tests revealed both a high within-day (i.e., ICC, > 0.90; CV%, range 1.8-8.1%) and between-day reliability (i.e., ICC, > 0.80; CV%, range 4.1-12.3%). The principal component analyses performed separately on both tests revealed factor structures that suggest a high level of generalizability of the individual dependent variables across the tested muscle groups. Finally, despite being about 20% lower, the peak force obtained from CMC highly correlated with the maximum voluntary force of SST.

Discussion: The present data suggest that the variables derived from CMC could be as reliable as the variables obtained from SST. Moreover, in addition to presumably capturing muscular action typical for rapid and/or consecutive action of antagonistic muscle groups, the peak force could also assess the maximum voluntary force exerted during a sustained contractions. Although the external validity of CMC still remains to be explored, the present findings support development of CMC into a standard test of neuromuscular function.

THE RATE OF TORQUE DEVELOPMENT OF A BALLISTIC CONTRACTION PRECEDED BY A RAPID ANTAGONIST CONTRACTION: EFFECT OF THE CHARACTERISTICS OF THE ANTAGONIST CONTRACTION

RICHARTZ, C., LÉVÉNEZ, M., DUCHATEAU, J.

UNIVERSITÉ LIBRE DE BRUXELLES

The rate of isometric torque development is greater when a rapid (ballistic) contraction is preceded by a rapid contraction of the antagonist muscles compared with a ballistic contraction performed from a resting condition (Richartz et al., Comput Methods Biomech Biomed Engin,10 (S1):150-151, 2007). In the current study, we investigated the influence of the torque produced during the antagonist contraction on the rate of isometric torque development in the subsequent ballistic agonist contraction.

Eleven healthy subjects participated in this investigation. They seated on a chair with their right foot strapped to a footplate. The task consisted successively: (1) to sustain a submaximal force (20% MVC) with the dorsiflexors, (2) to perform a rapid contraction with the plantar-flexors (antagonists) and (3) to produce, without transition, a ballistic contraction with the ankle dorsiflexors. The experimental session was divided into three parts that were executed in a random order: agonist contractions of different torque levels (25%, 50% and 75% MVC) were preceded by an antagonist contraction of 25%, 50% and 75% MVC. We recorded the isometric torque produced by the plantar- and dorsiflexor muscles and the EMG activities of both agonist (tibialis anterior) and antagonist (soleus and gastrocnemii) muscles by means of two surface electrodes placed over each muscle.

The results show that the rate of agonist torque development was significantly enhanced with the increase in antagonist torque (ANCOVA, $P<0.001$). The agonist-antagonist coactivation ratio during the ballistic agonist contraction was measured at 4 different time points (25ms and 50ms after the onset of the agonist contraction, at peak velocity and at half of the integrated EMG) and was significantly enhanced only when the antagonist torque reached 75% MVC. The ratio at 50ms was 1,39 ± 0,07, 1,41± 0,08 and 1,64 ± 0,05 for 25%, 50% and 75% respectively. Furthermore, in almost 45% of these contractions, a time interval (TI) between the end of the antagonist contraction and the onset of the agonist contraction appeared during which none of the four investigated muscles presented any EMG activity. Interestingly, the contractions where TI was observed showed a significant increase in rate of agonist torque development (ANCOVA, $P<0.001$).

In conclusion, this study shows the presence of TI in all of the involved muscles in about half of the contractions when a ballistic action is preceded by a rapid submaximal contraction of their antagonist muscles. TI might contribute to increase the rate of torque development during a subsequent ballistic contraction. As both the rate of agonist torque development and coefficient of coactivation are significantly increased with the antagonist torque developed it is suggested that, even in isometric conditions, the stretch-shortening cycle may play a major role in the increased rate of torque development of a ballistic contraction.

INCREASED PROTEIN INTAKE REDUCES LEAN BODY MASS LOSS DURING WEIGHT LOSS IN ATHLETES

METTLER, S., MITCHELL, N., TIPTON, K.D.

1. UNIVERSITY OF BIRMINGHAM, BIRMINGHAM, UNITED KINGDOM, 2. ETH ZURICH, ZURICH, SWITZERLAND, 3. ENGLISH INSTITUTE OF SPORT, SHEFFIELD, UNITED KINGDOM

Purpose:

To examine the influence of dietary protein on lean body mass loss and performance during hypoenergetic weight loss in athletes.

Methods: In a parallel design, 20 healthy, young, resistance trained athletes were examined for energy expenditure for one week and fed a fully controlled mixed diet (15% protein, 100% energy) in the second week, followed by a hypoenergetic diet (60% of the habitual energy intake), containing either 15% (~1.0 g∙kg-1) protein (control group, n=10) or 35% (~2.3 g∙kg-1) protein (high protein group, n=10) for two weeks. Subjects continued their habitual training throughout the study. Total, lean body and fat mass, performance (squat jump, maximal isometric leg extension, one repetition maximum bench press, muscle endurance bench press and 30 sec wingate test) and fasting blood samples (glucose, non esterified fatty acids (NEFA), glycerol, urea, cortisol, free testosterone, free IGF-1 and growth hormone) were examined at the end of each of the four weeks.

Results: Total (-3.0 ± 0.4 kg and -1.5 ± 0.3 kg for the control and high protein group, respectively, $p=0.036$) and lean body mass loss (-1.6 ± 0.3 kg and -0.3 ± 0.3 kg, $p=0.006$) were significantly larger in the control group compared to the high protein group. Fat loss, performance and most blood parameters were not influenced by the diet. Urea was higher in the high protein group and NEFA and urea showed a group*time interaction.

Conclusion: These results indicate that ~2.3 g∙kg-1 or ~35% protein was significantly superior to ~1.0 g∙kg-1 or ~15% energy protein for maintenance of lean body mass in healthy young athletes during hypoenergetic weight loss.

THE EFFECT OF WEIGHT REDUCTION RATE ON BODY COMPOSITION, THYROID HORMONES AND BASAL METABOLIC RATE IN ELITE ATHLETES

KOIVISTO, A., GARTHE, I., SUNDGOT-BORGEN, J.

UNIVERSITY OF OSLO, NORWEGIAN SCHOOL OF SPORTS SCIENCES, NORWEGIAN OLYMPIC SPORTS CENTRE

Background: Optimal body composition and body weight (BW) are important performance factors in sports that emphasize aesthetics and high power to weight ratio. Weight reduction guidelines for athletes today suggest a weekly weight loss of 0.5-1.0kg which corresponds to 0.7% and 1.4% of BW in a 70-kg athlete (1). Weight reduction may lead to loss of lean body mass (LBM) and changed thyroid hormone profile and thereby reduced basal metabolic rate (BMR). Combining resistance training with energy restriction may reduce loss of LBM in overweight subjects (2). Purpose: To compare changes in body composition, thyroid hormones and BMR in two different weight-loss interventions promoting loss of 0.7% versus 1.4% of BW per week in elite athletes. Methods: 30 male and female elite athletes

were randomized in to slow weight reduction ["SLOW", n=14, 23.5± 3.3y, 72.1± 12.2kg] and fast weight reduction ["FAST", n=16, 22.3± 4.7y, 72.2±11.3kg]. Both interventions included energy restricted diets and resistance training regimen for 6-12 weeks. The duration was dependent on the desired weight loss and the random allocation to one of the interventions. Diets were recorded by a 4-day weighed food records which were used to design individual meal plans promoting weekly BW loss of 0.7% or 1.4%. Four weekly resistance training sessions were added to the usual training regimen to stimulate muscle hypertrophy. The following measurements were taken at the baseline and post intervention: BW, LBM, FM with dual energy x-ray absorptiometry (DEXA), s-THS and s-free T4 and BMR with indirect calorimeter. Results: There were no significant differences between the groups in any variables at the baseline. BW was reduced by (5.6± 3.0%, p<0.001) and (5.4± 2.3%, p<0.001) for SLOW- and FAST-group, respectively. The changes were not significantly different between the groups (p=0.8). LBM was significantly increased for SLOW (2.0± 1.3%, p<0.001) but not for FAST (1.1± 3.0%, p=0.3). There was a significant difference in change of FM between the groups SLOW (-31± 2.9%, p<0.001) and FAST (-23.4± 13.8%, p<0.001)(p=0.04). Free T4 reduction was significant in FAST (-11.2± 7.6% , p=0.001) but not in SLOW. These changes were significantly different between the groups (p<0.001). BMR reduced significantly for both SLOW (-12.3± 11.4%, p=0.036) and FAST (-9.8± 6.5%, p=0.018), but did not differ between the groups (p=0.9). Conclusion: For optimal body composition changes in athletes a moderate energy restriction combined with resistance training leading to a weekly weight loss of 0.7% seems preferable. Despite maintained or increased LBM, athletes experienced reductions in BMR.

THE EFFECT OF TWO DIFFERENT WEIGHT-GAIN INTERVENTIONS ON BODY COMPOSITION AND PERFORMANCE IN ELITE ATHLETES

GARTHE, I., RAASTAD, T., REFSNES, P., SUNDGOT-BORGEN, J.

THE NORWEGIAN SCHOOL OF SPORTS AND SCIENCES AND THE NORWEGIAN OLYMPIC SPORTS CENTRE

Because muscle mass is an important determinant of performance in sports dependent on high muscle strength or power (e.g. weight lifting, alpine skiing), there is a need for effective muscle mass gaining protocols. The most important factors promoting an increase in muscle mass is strength training combined with positive energy balance, and an increase in body mass of 0.25-0.5 kg per week may be possible depending on genetics and the resistance-training history of the athlete (1,2). For Elite athletes with heavy training loads, competitions and limited time for proper nutrition strategies, it can be a difficult task to increase lean body mass (LBM) or to maintain LBM during the competitive season. Thus, a significant number of these athletes are using excessive supplementation and diets high in saturated fat. Purpose: To evaluate the effect of nutritional guidance in a 10-12 weeks weight-gain period in elite athletes. Methods: 39 male and female elite athletes where randomized into two groups, "nutritional guidance group" (NG, n=21, 19.1±2.9 y, 70.9±8.9 kg) and "ad libitum group" (ALG, n=18, 19.6±2.7 y, 75.0±5.9kg). The Athletes in NG followed a strict meal plan based on a 4-day weighed food registration, providing a positive daily energy intake corresponding to 544±143 kcal whereas the athletes in the ALG had an ad libitum energy intake with no nutritional guidelines. All athletes continued their normal sport specific training (16.7±5.4h per week), and in addition all included four resistance-training sessions per week to emphasize muscle hypertrophy. Assessments done pre and post intervention were: body weight (BW), dual energy x-ray absorptiometry (DEXA), 1 RM tests (squat and bench press and bench pull). Results: The energy intake during the intervention period was significantly higher in the NG than in the ALG (3585±601 vs. 2964±884 kcal, respectively). BW increased with 3.9±0.6% in NG and 1.5±0.4% in ALG. Total LBM increased by 2.7±0.4% in the NG but was not significantly changed in the ALG (1.8±0.4%, p=0.6). There was larger increase in fat-mass in NG (14.7±3.7%) than in ALG (2.5±2.6%). Strength performance was improved in both the NG and ALG in 1 RM bench press (11.5±8.5% and 9.0±1.8%), in 1RM squat (9.1±1.4% and 11.5±2.0%) and in 1 RM bench pull (9.0±3.4% and 6.1±1.6%), respectively. Conclusion: In terms of reaching their weight-gain goals, the athletes in NG was significant more successful than the ALG. Due to long history of heavy strength-training, the athletes had limited possibilities to increase LBM and performance in these variables. For overall body composition goal, the excess energy intake in a weight-gain protocol should be considered carefully since greater rates of gain are likely to include increments in body fat storage in trained athletes.

IMPACT OF LONG TERM HYPOCALORIC DIET ON EXERCISE-INDUCED SUBSTRATE UTILIZATION AND AEROBIC CAPACITY IN OBESE SUBJECTS

HAUFE, S., ENGELI, S., HERMSDORF, M., OTTO, C., LUFT, F.C., JORDAN, J., BOSCHMANN, M.

FRANZ VOLHARD CLINICAL RESEARCH CENTER

Introduction: Obesity is often associated with reduced aerobic capacity (AC) and impaired exercise induced fat oxidation (Blaak, 2004). We aimed to investigate the effects of a prolonged hypocaloric low fat (LF) and low carbohydrate (LC) diet on substrate utilization and aerobic capacity in obese subjects.

Methods

We included overweight to obese (BMI: age: 33.8 ± 4.2) but otherwise healthy subjects who participated at a 6-month hypocaloric diet with either a low proportion of carbohydrate (LC: n=19) or fat (LF: n=17) to total energy intake. Subjects were advised to keep their current physical activity level during the dietary intervention. Substrate oxidation and aerobic capacity (expressed as maximum oxygen uptake) was determined using an incremental exercise test with indirect calorimetry. For each individual oxygen uptake (VO2), carbon dioxid production and respiratory quotient were averaged every 10s intervals throughout the exercise test. To assess whole body substrate oxidation we applied stoichiometric equations with appropriate energy equivalents (Frayn, 1983). Area under the curve was calculated for fat (AUCfat) and CHO (AUCcho) using the whole slope for FAT and CHO vs. workload.

Results: Absolute aerobic capacity (VO2max in l/min) did not change in either group. Related to body weight (relative AC) increases were observed in LC (22.7 ± 5.6 to 25.4 ± 4.5 ml/min/kg, p<0.05) and LF (23.2 ± 5.8 to 25.9 ± 6.9 ml/min/kg, p<0.05). Whole body fat oxidation was enhanced after 6 month of diet independent of macronutrient composition (LC: AUCfat + 22%; LF: AUCfat+ 20%; ns) whereas CHO oxidation only changed marginal. Accordingly the respiratory quotient was slightly lower throughout the exercise test in both groups.

Conclusion

Our data indicate that fat oxidation tended to increase after long term dietary intervention independent of the ratio between fat and carbohydrate to total daily energy intake whilst CHO oxidation seems not to be affected. The improvement in relative aerobic capacity was likely due to the reduced bodyweight considering that absolute aerobic capacity was unchanged. A 6 month hypocaloric diet without additional participation in physical activity does not influence aerobic capacity or substrate oxidation to a significant extent during exercise.

ACUTE EFFECT OF EXERCISE PERFORMED IN THE HEAT ON ENERGY INTAKE IN ACTIVE MALES

GUELFI, K.J., SHORTEN, A.L., WALLMAN, K.E.

THE UNIVERSITY OF WESTERN AUSTRALIA

Introduction: Maintenance of a healthy body weight is achieved when there is a balance between energy intake and energy expenditure. However, the effect of exercise itself on subsequent energy intake is not well understood. In particular, the environmental temperature in which exercise is performed may influence energy intake in the post-exercise meal. This study examined the effect of an acute bout of exercise performed in the heat on energy intake, macronutrient selection and preferences for solid food or drinks in the subsequent meal.

Methods: Eleven active males completed three experimental trials in a randomised counter-balanced design; exercise in the heat (36 C: HEAT), exercise in a neutral temperature (25 C: NEUT) and a resting control trial (25 C: CON). The exercise trials consisted of treadmill running for 40 min at 70% VO2 peak. Following exercise or rest (control), participants were presented with a buffet-style breakfast of precisely known quantity and nutrient composition from which participants could consume ad libitum. From this, total energy intake and consumption of each specific macronutrient was determined.

Results: There was no significant difference in total post-exercise energy intake between HEAT and NEUT. However, participants consumed significantly more energy during NEUT compared to CON ($p = 0.007$). When accounting for the excess energy expended during exercise, relative energy intake (REI) during HEAT was significantly lower than CON ($p = 0.001$), while there was no significant difference in REI between the two exercise trials or between NEUT and CON. The lower REI following HEAT compared to CON, but not NEUT could not be accounted for by significant differences in the circulating level of blood glucose or lactate between exercise trials ($p > 0.05$). In contrast, body temperature was significantly elevated following exercise in the HEAT until the breakfast meal, a factor which may inhibit post-exercise energy intake. With respect to macronutrient preferences, there were no significant differences in carbohydrate, fat or protein intake following the exercise trials, but there was a significantly greater intake of carbohydrate following NEUT compared to CON ($p = 0.007$). Also, a significantly greater proportion of kilojoules were consumed in the form of drinks during both exercise trials compared to CON.

Discussion: In summary, when accounting for the excess energy expended during exercise, energy intake is lower following exercise in the HEAT compared to rest in healthy males. Conversely, REI is similar following exercise in NEUT compared to rest. These findings suggest that exercise performed in a warmer environmental temperature may be favourable for achieving acute negative energy balance.

HYDRATION STATUS OF THE OFF-ROAD BIKERS IN THE OFFROAD FINNMARK 2008 TESTRACE

MIKKILÄ, S., WEYDAHL, A.

FINNMARK UNIVERSITY COLLEGE

Offroad Finnmark 2008, a testrace for the 700 km one-stage off-road biking race took place in Alta, northern Norway. The race had 11 checkpoints with 3 mandatory 2hours stops. An adequate hydration status can be challenging to maintain during this prolonged exercise. Dehydration reduces the exercise performance and may severely impair essential body functions(1). The purpose of the study was to describe the hydration status throughout this physically demanding race.

Five well-trained (VO2max 73.3+/-7.5 ml/minxkg) male amateur bikers participated in this study. Urine samples for osmolality (Uosm) and specific gravity (Usg) were collected a week before the race, during the race at 6 checkpoints and right after the race. The pre-exercise samples with restricted fluid intake were analyzed to confirm bikers' normal renal function. The other samples were analyzed to determine dehydration during the race. Uosm samples were analyzed with a freezing point osmometer and Usg samples with a hand-held refractometer. The fluid intake during the race was registered at the same 6 checkpoints as urine samples were collected and right after the race. The registration was based on the bikers' recitations. Dehydration was determined by using the cut-off values of Uosm =/>900 mosm/kg H2O and Usg=/> 1.020.

A total of 33 urine samples were collected. Three bikers completed the race giving each 8 samples. Two bikers quitted the race due to injuries. However, one of them gave 4 and the other 5 samples.

A biker completing the race showed dehydration with all checkpoint samples by using the Uosm criteria. By using the Usg criteria, this biker was dehydrated the entire race. Another biker completing the race showed mild dehydration at one checkpoint by using the Usg criteria. The biker who broke the race after giving 3 checkpoint samples, was dehydrated at 2 checkpoints by using the Uosm criteria and at 3 checkpoints by using the Usg criteria.

Fluid intake of the bikers during the race was 6113+/- 643 ml/24 hours. The biker, breaking the race and showing dehydration with 2 of the Uosm and 3 of the Usg samples had the lowest fluid intake. The biker, who finished the race and showed dehydration throughout the entire race with the Usg and at 6 checkpoints with the Uosm had the highest fluid intake. Most likely the bikers' recall of the fluid intake is not accurate as well as the fluid contents of the meals are not calculated.

The results show that maintaining an adequate hydration status was individually demanding.

However, the study shows that the dehydration was not a major problem during Offroad Finnmark 2008.

WHAT MATTERS FOR WELL-BEING IN ELDERLY: PHYSICAL FUNCTION OR PERCEIVED PHYSICAL HEALTH? PRELIMINARY DATA FROM A RANDOMIZED CONTROLLED TRIAL

SOLBERG, P.A., KVAMME, N.H., HALVARI, H., OMMUNDSEN, Y.

NORWEGIAN SCHOOL OF SPORT SCIENCES

One important question in the exercise and well-being relationship concerns the role of physical fitness (McAuley & Rudolph, 1995). Several studies report exercise to result in significant physiological improvements, but such changes do not always lead to improved well-being (e.g., Blumenthal et al., 1989). According to Rejeski and Mihalko (2001), it may rather be changes in perceived physical health that facilitate well-being effects of exercise in the elderly. Thus, the aim of the present study was to explore the relationships between physical and psychological indices of health and well-being in a group of elderly.

The sample was drawn from community-dwelling elderly volunteers (N= 68, *M* = 74.3 yrs, 67.6% women). Measures included a) Functional tests: Stair climb, gait speed, chair raise, 6 min walk test, timed up and go and functional upper body; b) Psychological measures consisting of a) 5-item measure of Perceived physical health (PPH); b) Subjective well-being (SWB) comprised of the Positive and Negative Affect Schedule (PANAS), Satisfaction With Life Scale (SWLS) and Center for Epidemiological Studies Depression Scale (CES-D); c) Eudaimonic well-being was measured with the Subjective Vitality Scale (SVS). All psychological measures yielded acceptable reliability (α's from .75 to .87).

Perceived physical health was significantly correlated with four of the six functional tests (gait speed, chair raise, 6 min walk test, and timed up and go). Physical function (a sum score of these four tests) correlated significantly with perceived physical health ($r = .34$, $p<.01$), but none of the two well-being indices. Perceived physical health was significantly correlated with SWB ($r = .46$, $p<.001$) and subjective vitality ($r = .27$, $p<.05$). Bootstrapping procedures (Preacher & Hayes, 2008) revealed that perceived physical health mediated the relation between physical functioning and subjective well-being (SWB) in elderly. No mediation effect was observed using eudaimonic well-being as outcome.

Preliminary findings suggest that gains of exercise in terms of physical fitness may be insufficient to obtain better well-being in the elderly. Rather, changes in perceived physical health may serve as a mechanism by which exercise enhance well-being. We will pursue these issues further in future analyses from our RCT.

THE EFFICACY OF PRIMING AS A MEANS OF PROMOTING FLUENT MOTOR BEHAVIOUR

ADAMS, D., ASHFORD, K.J., JACKSON, R.

BRUNEL UNIVERSITY

Breakdown of skill execution under pressure (referred to as choking, see Baumeister, 1984) is a common occurrence in sport so development of methods that promote fluent, autonomous performance is warranted. Research out with the sport domain indicates that priming methods can be successfully employed to manipulate attitudes and behaviours (e.g., Bargh & Chartrand, 2000); however, the applicability of priming to skilled motor behaviour is unclear and the processes through which priming effects behavioural change are poorly understood. Preliminary investigations within a motor skill context demonstrated that priming can promote positive performance effects and alleviate skill failure under stress (Ashford & Jackson, under review). The aim of the present study was to replicate this finding and measure the attentional demands associated with performing under different prime conditions through use of a probe-reaction time (PRT) task. Twenty-four university level soccer players completed a dribbling task under three priming conditions (skill focus, neutral, fluency) and a control condition. Priming was conducted using different versions of a sentence scrambling task. While dribbling the ball, participants were required to respond verbally with the word 'low' or 'high' to a pseudo-randomly presented auditory tone of either 250 or 500 Hz respectively. Task completion time, ball displacement from the midline, and probe reaction time served as dependent variables. Repeated measures ANOVAs revealed a significant main effect of prime condition for both task completion time, $F(2, 41) = 22.02$, $p < .001$ and probe reaction times, $F(2, 46) = 5.46$, $p < .01$, but not for ball displacement. Consistent with our hypothesis, the fluency prime yielded significantly faster task completion times and probe reaction times (5262 ms and 66 ms respectively) than were observed in the skill focus prime condition (5810 ms and 81 ms respectively). The results suggest that priming can affect skilled motor performance and that the effects of fluency and skill-focus primes are mediated by the attentional states they promote. Further research into the modifying properties of priming and, in particular, its effectiveness in the alleviation of skill failure under stress, is warranted.

IDENTIFYING SELF-REGULATORY BEHAVIOR IN YOUTH SOCCER PLAYERS: A QUALITATIVE INVESTIGATION

TOERING, T., ELFERINK-GEMSER, M., JORDET, G., JORNA, C., VISSCHER, C.

UNIVERSITY OF GRONINGEN, UNIVERSITY MEDICAL CENTER GRONINGEN

Self-regulation refers to processes by which individuals control their thoughts, feelings, and actions (Baumeister & Vohs, 2004). In the learning and development context, it is described as the extent to which individuals are metacognitively, motivationally, and behaviorally proactive in their learning process (Zimmerman, 1986). Talented youth soccer players possess characteristics that facilitate learning, training, and competition (Williams & Reilly, 2000). One of these characteristics may be self-regulation, since self-regulation helps individuals to learn more effectively. Previously, we have measured metacognitive and motivational self-regulation with a questionnaire, and found that elite youth soccer players outscored non-elite players on reflection and effort (Toering et al, 2008). However, we have not yet measured behaviors. If we want to know what these scores mean, thus how much more elite players reflect and invest effort than non-elite players, we have to relate them to overt behaviors (e.g., Andersen et al., 2007; Young & Starkes, 2006).

The purpose of this study was to identify self-regulatory behaviors of youth soccer players. Seven expert soccer coaches working with youth soccer players in a talent development program of a Dutch premier league club were interviewed. The interviewer gave definitions of metacognitive and motivational self-regulation, and the coaches were asked to describe behaviors they recognized as self-regulative or non-regulative behaviors during soccer training. Qualitative analysis resulted in a list of self-regulative and non-regulative behaviors, that could be captured in the following themes: focus, time-management, interaction with coach, interaction with team members, resilience, initiative, discipline, and 100% determination to execute tasks. The coaches considered the interaction with coach and team members, discipline, and 100% determination to execute tasks as most important in the development of youth soccer players.

THE ROLE OF SELF-REGULATORY SKILLS IN YOUNG TALENTED ATHLETES PLAYING TEAM SPORTS

JONKER, L., ELFERINK-GEMSER, M.T., VISSCHER, C.

UNIVERSITY OF GRONINGEN, UNIVERSITY MEDICAL CENTER GRONINGEN

Both in sports and academics it has been found that at the higher levels one typically finds more athletes or students with superior self-regulatory skills (Cleary & Zimmerman, 2001; Zimmerman, 1986). Self-regulation reflects a combination of metacognitive attributes, i.e., planning, self-monitoring, evaluation, and self-reflection, and motivational attributes, i.e., effort and self-efficacy (Ertmer & Newby, 1996; Hong & O'Neill Jr., 2001). Unknown, however, is whether there is an association between these skills and: 1 sport competitive level and 2. level of education in highly talented athletes playing team sports.

In total 120 talented athletes playing baseball, basketball, handball, field hockey or volleyball filled in a questionnaire for self-regulatory skills (Herl et al., 1999; Hong & O'Neill Jr., 2001; Howard et al., 2000; Peltier et al., 2006). Of them, 33 competed at international sport competitive level (mean age: 14.9 years ± 1.09 years) and 87 competed at national level (mean age: 13.9 yrs ± 1.01). Data were analysed using MANCOVA with the self-regulatory skills as dependent variables, sport competitive level and level of education as factors, and age as covariate.

The results of the MANCOVA showed no significant differences ($p>.05$) on the six self-regulatory aspects for sport competitive level or level of education which may mean that at the 'highest' sport performance levels a general feature as self-regulation is not discriminative. Yet, the possession of above average levels of self-regulation is a necessity for talented athletes in order to juggle the demands of their academic career with their extensive investments in sports (Moon, 2003). Although not statistically different, the results showed that the athletes competing at international level had higher scores on evaluation and self-reflection with moderate effect sizes: $d=0.50$ on both attributes.

With regard to our findings, it appears prominent that sport specific characteristics make the difference between the international elites and those performing at national level within team sports. Further investigation is warranted with respect to individual sports in which self-regulation is closely related to sport specific psychological skills (Anshel, 1995).

Nonetheless, our findings have important implications for people involved with talented athletes playing team sports. It would, for instance, be interesting to investigate in a longitudinal design whether self-regulation will enable promising athletes to optimally profit from their self-regulatory skills in their sports and academics.

RISKS FACTORS FOR BURNOUT AMONG ELITE ADOLESCENT HANDBALL PLAYERS

GAUTHEUR, S., GUILLET, E.

UNIVERSITÉ CLAUDE BERNARD LYON 1

Introduction: The purpose of the study was to examine the impact of self-determined motivation, anxiety and self-confidence on athlete burnout (Raedeke, 1997) in young elite handball players. A theoretical model based on the Self Determination theory (Deci & Ryan, 2002) was proposed to analyse these relationships. This model postulates that the least self-determined forms of motivation might lead to serious negatives consequences, such as lower self-confidence, higher anxiety, lower vitality, higher burnout and higher intentions to dropout.

It was hypothesized that an athlete with lower self-determined motivation would have higher anxiety, lower self-confidence, lower vitality, higher intentions to dropout, and would report higher risks to burnout at season's end.

Method: A sample of 309 French handball players (152 males and 157 females) participated in this study. They trained an average of 11 hours a week (SD = 3.5). Their average age was 15.4 years (SD = .90) and the average playing experience in their sport was 6.8 years (SD = 2.4). 62.1% were playing at a national level.

These athletes completed a questionnaire twice during the season, measuring: (a) sport motivation (EMS; Brière, Vallerand, Blais & Pelletier, 1995), (b) anxiety and self-confidence (EEAC; Cury, Sarrazin, Pérès & Famose, 1999), (c) subjective vitality (SSV; Ryan & Frederick, 1997), (d) future sport intentions (Sarrazin, Vallerand & Guillet, 2002), and (e) athlete burnout (ABQ; Raedeke & Smith, 2001).

Results / Discussion: A structural equation model (χ²/df = 2.18, RMSEA = .06, CFI = .95, NFI = .90) revealed that self-determination has (1) a mediating and (2) direct influence on burnout. (1) A player with lower self-determined motivation, higher anxiety, lower self-confidence, lower vitality at the beginning of the season, expressed feeling a lack of accomplishment at season's end. A player with lower vitality, higher intentions to dropout at the beginning of the season, had higher tendencies to devalue handball at the season's end. These findings bring new elements to light in our understanding of the athlete burnout. (2) A player with lower self-determined motivation at the beginning of the season reported higher symptoms of burnout at the end of the season. These results confirm previous study findings in that lower self-determined motivation increases the risk of burnout in young elite athletes.

DROPPING OUT OF ORGANIZED SPORT OR STAYING IN? A PROSPECTIVE STUDY ON THE INFLUENCE OF PSYCHOSOCIAL FACTORS

OMMUNDSEN, Y., ROBERTS, G.C., MILLER, B.W., SISJORD, M.K., FASTING, K., SØRENSEN, M.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Participation in organized youth sport across childhood and adolescence increase the likelihood of being physically active in adulthood (Telama et al 2006). Hence, preventing young people from dropping out of organized sport may be seen as an important health promotion strategy.

Study purpose

To examine the influence of a theoretically informed set of environmental and personal factors on young athletes' dropout from organized sport.

Method: Prospective design including a sample of 698 athletes aged 12-16 years from different sports who provided T 1 (early season) data and responses regarding their participation status the following sport season (T 2). T 1 predictors comprised perceptions of the sport environment, cognitive mediators of motivation and persistence, regulation of motivation and affect.

Results: Direct logistic regression helped assess the impact of predictor variable set on the likelihood of next season dropout. The full model containing all predictors was statistically significant, X2 (13, N= 678) = 68,23, p<.001, indicating that the model was able to distinguish between athletes who reported and did not report having dropped out of organized sport. The model as a whole explained between 25% (Cox and Snell R square) and 36% (Nagelkerke R squared) of the variance in organized sport participation status, and correctly classified 84% of the cases.

Seven predictor variables made a unique statistically significant contribution to the dropout model. The strongest predictors - odds ratios of 2.13 and 1.82 - were a high performance climate and high perceived ability, respectively. Athletes, who early season perceived the climate as strongly performance oriented, were over 2 times more likely to report dropout than those who did not, controlling for all other factors in the model. Further, athletes high on perceived ability were 1.8 times more likely to report dropout than their counterparts. The odds ratios of perceived autonomy and relatedness were less than 1. Hence, for every additional level of agreement in terms of being socially integrated with peers in sport, athletes were .70 times less likely to report dropout, controlling for other factors in the model. Finally, boys were .60 times less likely to dropout of sport than were the girls, and younger athletes were .59 times less likely to dropout than older ones.

Discussion: Results reveal the importance of de-emphasizing social comparison and winning while simultaneously strengthening athletes' sense of autonomy and social bonds with their sport peers, and prevent negative affect. Findings also reveal that preventing dropout seem particularly important among girls and as athletes grow older. Findings also attest to the importance of challenging high ability athletes in accord with their sport abilities.

THE EFFECT OF COOPERATIVE PHYSICAL ACTIVITIES ON THE GROUP STRUCTURE OF PUBESCENT, MOTOR-DISABLED CHILDREN

KOVÁCS, K., SZILÁRD SÁRINGER, Z.

SEMMELWEIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES, PETő ANDRÁS TEACHER TRAINING AND TRAINING INSTITUTE OF THE MOTOR DISABLED

Earlier studies in applied pedagogy (Newcomb, Bukowski, Pattee, 1993) have shown that one of the traits of practical cognitive aspect is that the development of an aptitude for thinking is the solution for most educational problems. In spite of the fact that the quality of social interactions has a major impact on performance. Physical skills and/or social qualities and abilities must be used as an educational tool to develop personality. Indeed, in a good group the students require the support of each other and benefit from the cooperative attitude as well as from their performance (N. Kollár, 1997).

In our earlier studies (Kovács, 2004, 2006) we found that in small groups (14-18 students), that 3-4 months of regular cooperative physical activity has a positive impact on group structure. The overall position of the girls in the experimental group shifted in a positive direction while in the control group the position of the students either deteriorated or did not change.

In this study we map changes to the group structure and sociometric status of motor disabled children marginalized by their peers under the influence of performance-oriented and competitive rowing practice three times a week.

We hypothesize that the necessity to work together during the physical exercise program would have a positive impact on group structure and reduce the degree by which students on the group periphery were marginalized by their peers.

The participants were 11-15 years old (N=15) motor disabled children, who traveled by bus to training. The students depended upon each other from the beginning of the bus trip until end of the training. Their success and enjoyment of each session required coordinated teamwork.

Sociometric status was measured with Shellenberger's Group-Evaluative Method (1990). We extended the matrix (Kovács, 2005) to the 'Y' axis, graphing the average score the student gave to each classmate regarding how willingly they would make a joint decision.

As successful cooperation depends on working together, the answers to the decision question will mirror social abilities.

The initial group structure was very similar to that observed in our earlier studies. The students favored two of their peers, and strongly marginalized 3- 4 of them.

In our presentation we graphically present the effect of 10 weeks' cooperative program on the group's structure, and the sociometric distance between students.

RECRUITING PEOPLE WITH DISABILTIES TO NORWEGIAN SPORT

THORESEN, T., FASTING, K., SAND, T.S., SISJORD, M.K., BROCH, B.T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: This paper presents some results from a study documenting the current state of equality within Norwegian sports and fitness activities, especially with regard to gender. The project was initiated in 2007 by The Norwegian Equality and Anti-Discrimination Ombud, and carried through by a research group at the Norwegian School of Sport Sciences. The Norwegian Sports for the Disabled Association was dissolved on 1. September 2007, after the national sporting associations passed a resolution that they would commit to taking responsibility for organising sports for the disabled.

The results discussed in this paper answered this question: To what extent is work being done at the various organisational levels to facilitate and recruit people with disabilities?

Methods: Representatives from 24 individual sport associations, 6 regional confederations and 43 clubs were interviewed. In addition, the researchers reviewed their annual reports, strategy documents and action plans.

Results: A great deal of work is done in order to accommodate and recruit people with disabilities. This is related to the fact that, however, that there are large variations with regard to how much work has been invested in this endeavour, even if there is a high degree of awareness with regard to the articulated goal of integration.

Several associations refer to the fact that recruitment among people with disabilities represents a big challenge, and point to difficulty in making contact with people with disabilities and reaching them with information. Some associations also pointed out that it was a big challenge to get the clubs to take responsibility for the integration of disabled people.

Many of the teams mentioned challenges connected to the involvement as a limiting factor. It appears that many of the disabled people that are active in teams are children, while the accommodation

and inclusion of disabled adults is perceived to be a great deal more difficult. There appear to be few disabled people who are active as board members, coaches and officials.

Discussion: One challenge regarding recruiting people with disabilities seem to be their dependence on help and facilitation for doing sports and to become board members. Therefore the results are discussed on the background on Norwegian social politics with refer-

ence to full integration and equality and the impact it may have on Norwegian sports organisations. Theories on empowerment and empowerment language and how these theories are used to facilitate activities are used as theoretical fundaments in the discussion.

UPPER LIMBS LEAN MASS AND STRENGTH IN CHILDREN WITH DOWN SYNDROME

GONZÁLEZ DE AGÜERO, A., VICENTE-RODRÍGUEZ, G., ARA ROYO, I., MORENO, L.A., CASAJÚS, J.A.

UNIVERSITY OF ZARAGOZA

Introduction: It is known that people with Down syndrome (DS) are hypotonic (Pueschel, 1990; Sakadamis et al., 2002) and they have "soft" muscles. This hypotonicity could be the cause of the lack of strength in this population.

Material and methods: 30 children (17 male) with DS, mean age 14.7±3 yr. were compared with 30 healthy and without mental retardation (MR) children, matched in age and sex. The upper limbs lean mass of the subjects was measured using dual energy X-ray absorptiometry (DXA). Forearm strength was assessed with a maximal handgrip dynamometry in both hands. Dividing the kilograms of strength the performed in the dynamometry by the kilograms of upper limbs lean mass, we obtained an index of relative strength (IRS) that indicates the amount of kilograms of strength by one kilogram of lean mass in the upper limbs. Differences in the IRS between groups established using Student's unpaired t test and analysis of covariance was performed to test the differences in the upper limbs lean mass adjusting by height and Tanner maturational status.

Results: children with DS had, statistically, increased lean mass in the upper limbs compared with control children; however the IRS was 46% lower in the children with DS (both $p<0.05$).

Discussion: adjusting by height and Tanner stage, children with DS have more lean mass in the upper limbs than the children without MR; however they cannot produce too much kilograms of strength by kilogram of lean mass. Physiological impairments could explain these results. Further studies are needed on this topic, testing different muscular groups, i.e. lower limbs.

EFFECTS OF PHYSICAL EXERCISE ON FITNESS IN ADULTS WITH MENTAL RETARDATION: INFLUENCE OF SPORT SPECIALIZATION

FRANCIOSI, E., GUIDETTI, L., EMERENZIANI, G.P., BALDARI, C., PES, G., GALLOTTA, M.C.

UNIVERSITY OF ROME "FORO ITALICO"

Introduction: Exercise and physical fitness are considered important for health and well-being for individuals with mental retardation (MR) (Van de Vliet et al., 2006; Frey et al., 2008). The modern literature is poor in relation to sport specialization in athletes with MR. The aims of this study were to assess the physical fitness profile in athletes with MR in comparison with individuals who were included in recreational and leisure activity programs (non-athletic people); the contribution of sport specialization on athletes' fitness; and to analyse the correlation of each fitness component with subjects' MR levels.

Methods: A sample of sixty-four subjects aged 18-45 years (MR: Mild 38%, Moderate 22%, Severe 38%, and Profound 3%) composed by 22 track and field athletes, 19 basketball athletes, and 23 non-athletic people participated in this study. All participants were assessed before and after a 6-months period through fitness tests adapted to individuals with MR, including anthropometric measurements (height, weight, body mass index, and % body fat), Sit and reach test assessing the flexibility (FLEX), Hand grip test assessing the arm muscular strength (HG), Sit-ups and Push-ups tests assessing the muscular strength and endurance (SUT and PUS), Standing long jump test assessing the explosive leg power (ExLP), Step test assessing the cardiovascular endurance (VO2max), Flamingo test assessing general balance (BAL), and finally Timed up and go test assessing the motor coordination (MCoord).

Results: The results showed that participants' weight, body mass index and BAL were significantly affected by time ($p<0.01$); the ExLP was significantly affected by activity ($p<0.01$); and VO2max, HG, PUS, SUT, and Mcoord were significantly affected by interaction time and activity ($p<0.01$). Only track and field athletes increased significantly the VO2max ($p<0.05$). All athletes improved significantly in HG, PUS and SUT (track and field: $p<0.05$, $p<0.01$, and $p<0.05$ respectively; basketball: $p<0.01$, $p<0.05$, and $p<0.01$ respectively), instead non-athletic people decreased significantly in SUT ($p<0.01$). MCoord improved significantly in track and field athletes ($p<0.05$), and decreased significantly in no-athletic people ($p<0.05$). MR level was positively correlated to MCoord (p≤0.01, r=0.403).

Discussion: The findings of this study showed that physical activity improved fitness in adult individuals with MR, decreasing health risks. Moreover, these improvements were related to sport specialization. Finally, athletes with lower MR obtained higher performance scores in motor coordination test.

LATERALITY AND FRAGILE X SYNDROME

NIORT, J., HERNÁNDEZ VÁZQUEZ, F.J., BOFILL RÓDENAS, A.

INSTITUT NACIONAL D'EDUCACIÓ FÍSICA DE CATALUNYA

Introduction: Fragile X Syndrome (FXS) is a hereditary intellectual disability linked to X chromosome. Individuals with intellectual disability could be left-handed or ambidextrous (Carlier et col., 2006; Gérard-Desplanches et col., 2006). In the works of Cornish, Pigram & Shaw (1997), the FXS presents preferably left-handedness in comparison to Down syndrome and control groups. In the works of McManus & Cornish (1997), the persons FXS are right-handed and resemble the control group without handicap.

Methods: The experimental group is composed by 19 boys, aged between seven and thirty seven years old, studying in special schools, in ordinary schools or working in special workshops or ordinary businesses. The control group is composed by 19 individuals without

handicap studying in secondary schools. The method is the test of handedness preference by Annett (1970) that we have adapted for our study. We have included three test for measuring footedness, two for eyedness and one for eardness.

Results: The first results confirm the preference of right-handedness in persons FXS and provide new data regarding footedness, sensorial laterality. The persons FXS presents inconsistent footedness and ocular cross laterality.

Discussion: Our results are in the same way than the works of McManus & Cornish (1997). We know problems that the children FXS have with the sensorial integration. A cross laterality and a difficult sensorial integration can give the same problems for learning and for social-affective life. We cannot explain, nowadays, what influence more about education regarding control group submit also a high frequency of cross laterality.

CORRELATION BETWEEN COURSE NAVETTE AND HANDGRIP AS A PREDICTOR OF THE LEVEL OF PHYSICAL CONDITION IN INTELLECTUAL DISABILITY

BOFILL RÓDENAS, A., GUERRA-BALIC, M., PORCAR-RIVERO, C., SAN-MOLINA, J.

1. INSTITUT NACIONAL D'EDUCACIÓ FÍSICA DE CATALUNYA, 2. FPCEE- BLANQUERNA, UNIVERSITAT RAMON LLULL, 3. FACULTAT DE MEDICINA. UNIVERSITAT DE GIRONA.

Introduction: The purpose of the study was to describe the relationship between the results obtained in a multistage run field test "Course Navette" to evaluate the aerobic capacity in relation to the right Handgrip results to measure strength in population with Intellectual Disability (ID).

Methods: 8 individuals with Down Syndrome (DS), 13 individuals with Intellectual Disability but without Down Syndrome (ID-non-DS) volunteered for this study. They were 29±7,3 years of age, and they presented a mild or moderate level of ID. An initial familiarization session was performed before the study, and an informed consent was obtained. All of them performed a Course Navette test and a right Handgrip test at 30°, twice separated by one week.

Results: individuals ID-non-DS presented better absolute values in Course Navette (3,61±2,65min) than the ones obtained in population with DS (1,8±0,7 min). The same occurred as expected with strength (ID-non-DS=46,7kgW vs. SD=35,6kgW). The relationship in all individuals in both tests presented a significative correlation of 0,649

Discussion: 1) Field testing is easier to perform, and useful for exercise prescription. 2) ID-non-DS perform better, both, Course Navette and handgrip. 3) There is a significant correlation between both tests in population with ID that may allow the prediction of aerobic capacity through handgrip. 4) More research is needed increasing the sample to verify these results with laboratory testing.

THE EFFECTS OF TAPING ON UPPER TREPEZIUS ELECTROMYOGRAPHIC ACTIVITY AMONGST PATIENTS WITH SUSPECTED SUBACROMIAL IMPINGEMENT AND ANTERIOR GLENOHUMERAL SUBLUXATION. A PILOT STUDY

PAPANDREOU, M., BILLIS, E., GIATRAKOU, S., PARASIRI, T., TSEPIS, E., FOUSEKIS, C., KOUTSOJANNIS, C.

DEPARTMENT OF PHYSIOTHERAPY, BRANCH DEPARTMENT OF AIGION, TECHNOLOGICAL EDUCATION INSTITUTE (T.E.I) OF PATRAS, GREECE

Purpose

Of the most commonly encountered clinical sign in shoulder patients is loss of muscular control around scapula. One of the muscles which is subject to electromyographic (EMG) alterations is trapezius. Especially its upper fibres are found to be overactivated leading to limited upward scapular rotation (Ludewig et al. 2004). Scapular taping is suggested as a method of improving both, muscular control

and scapular position (Selkowitz et al. 2007, Hsu et al. 2009). The aim of this study is to explore the electromyographic activity of upper trapezius following the application of tape in patients with suspected subacromial impingement and anterior glenohumeral subluxation.

Methods: 9 women (mean age:34,7) with suspected subacromial impingement, 4 of which had co-existent anterior subluxation, and 7 healthy females (mean age:22) who served as controls, volunteered to participate in this pilot. Subjects were requested to perform abduction in the scapular plane with and without the application of tape. Abduction was performed without a weight and with a 1,5 kg weight on the affected hand. Two taping techniques were utilised, 'relocation of head of humerus' and 'inhibition of the upper trapezius muscle' (McConnell, 1994). Bipolar surface electrodes (Ag/AgCl, 4-cm diameter, 25-mm interelectrode distance) were applied over upper trapezius. Changes in frequency (F) and root mean square (RMS) of the power spectrum were calculated using the Viking-Quest equipment (Nicolet Inc.). F (frequency domain) and RMS (time domain) are the considered parameters describing motor unit activation patterns. Total time of the effort during EMG measurement was also analyzed. 5 measurements were provided for each test. Changes within groups were examined by utilising paired t tests for parametric and Wilcoxon signed rank tests for nonparametric data.

Results: For abduction mean RMS was highly statistically significant (p=0.01). Lower values were found with the tape application (115.3±35.3) than without tape (212.7±30.4). Results for abduction with the weight also yielded statistically significant results (p=0.02) with again, lower values with (177.5±35.3) compared to without the tape (297.3±37.4). In the control group, no significant decrease in the activation of motor units was yielded following the tape. The results suggest that in our patients upper trapezius, when taped, significantly decreased its activation.

Conclusions

These preliminary findings provide some evidence that taping facilitates the inhibition of potentially overactive upper trapezius muscle in patients with subacromial impingement and anterior glenohumeral subluxation.

SCAPULATHORACIC MUSCLE ACTIVITY DURING PUSH UP EXERCISE ON AN UNSTABLE VIBRATING SUPPORT SURFACE

MORK, P.J., SANDVIKMOEN, T.E., SEILER, S.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

Introduction: The Redcord 'Neurac' approach is frequently used by clinicians for treatment of neck/shoulder pain. It is hypothesized that application of high frequency vibration to the slings improves the success rate in treating neck/shoulder patients by facilitating activation of pain inhibited muscles. At present, it is not clear whether vibration applied to the slings acts to increase activation of scapulathoracic muscles. The aim of this study was to determine whether push-up exercises performed in slings (with and without vibration) induce elevated surface electromyographic (sEMG) activity of scapulathoracic muscles compared to push up exercise performed on a stable surface.

Methods: Eight subjects (7 males, 1 female; mean age 28 yrs, SD 7 yrs) were recruited from a convenience sample of university students and faculty. Bilateral sEMG was recorded (Myomonitor III, Delsys, US) from upper, transverse, and lower trapezius, serratus anterior, infraspinatus, pectoralis major and anterior deltoid while maintaining a regular push up position and a push up plus position with: 1) hands placed on a bench, 2) hands placed in slings, and 3) hands placed in slings with a 25 Hz vibration applied to the sling ropes. All exercise positions were maintained for ~20 sec (i.e., isometric contraction) while keeping the elbow joint in an extended position. Subjects rested 2 min between each exercise. All sEMG measurements was normalized by the highest root-mean-square detected sEMG response (EMGmax) obtained during maximal voluntary contractions. Median sEMG level (%EMGmax) was used to quantify sEMG activity.

Results: Pectoralis major was the only muscle displaying significantly higher sEMG activity during sling exercise compared to bench exercise (median sEMG level ~20-30% vs. 5-15% EMGmax). Overall there was no difference in sEMG activity between exercises performed with sling vibration compared to exercise performed without vibration. Push-up plus induced significantly higher sEMG activity during all exercise conditions compared to regular push-up for all muscles except anterior deltoid.

Discussion: Additional vibration to the slings did not increase scapulathoracic muscle activity under isometric, sub-maximal contraction conditions. Moreover, all muscles except pectoralis major showed similar sEMG level during sling exercise versus exercise on a stable surface. Our findings are consistent with previous studies showing no difference in scapulathoracic muscle activity when performing push-up exercises on stable versus unstable surface (e.g. Lehman et al 2008). Further studies are needed to elucidate why vibration applied to the slings seems clinically effective in reducing symptoms among neck/shoulder patients.

INFRARED THERMOGRAPHY AS A METHOD FOR MONITORING AND PREVENTING INJURIES IN SOCCER

NOYA, J., SILLERO, M., GÓMEZ, P.M., PASTRANO, R.

UNIVERSIDAD POLITÉCNICA DE MADRID

Introduction: Infrared thermography is considered as a valid and non-invasive diagnostic method [1] of different pathologies [2], including some musculo-skeletal problems as the lumbar pain [3]. Modern equipments make possible very accurate and objective recording of the body surface with a single picture. Recently, thermography has been purposed as a method not only for diagnosing but also for monitoring rehabilitation processes [4].

Methods: We recorded the body temperature of 23 professional players of the C.D. Toledo S.A.D. (Age= 24,9; SD= ± 3,5) on 24 days of its 2-months precompetitive period. Two thermographic pictures for each player (frontal and dorsal, of the trunk and lower limbs) were taken with a ThermaCAM TM SC640 (FLIR SYSTEMS, Portland) before starting the training season. Mean temperature of the muscular groups: abdominal (AB), quadriceps (Q,R&L), adductors (AB,R&L), anterior leg (AL,R&L), lumbar (L), hamstrings (H,R&L) and calves (C,R&L) and the joints: anterior knees (AK,R&L), posterior knees (PK,R&L), and ankles (A,R&L) were calculated from the pictures by the software 'ThermaCAM Reporter'. Additionally, the level of nuisance of those areas was assessed every day by the player from 1 (no pain) to 10 (injured). Temperatures were compared with the declared level of nuisance considering three groups (1 = No pain; 2 - 3 = Low pain; > 4 =

High pain). Areas affected by physiotherapeutic treatments were excluded from the sample. Rough reports and pictures from each player were daily reported to the physiotherapist of the team.

Results: ANOVA results point out a direct relationship between the declared level of nuisance of the area and its temperature both in ankles (F[AR] = 9.20; $p < 0.05$ and F[AL] = 3.99; $p < 0.05$) and knees (F[PKR] = 5.34; $p < 0.05$ and F[PKL] = 9.14; $p < 0.05$). There were also found significant differences for temperatures (aprox. 0.5 degrees) between the painful and non-painful limb on the knee (F[AK] = 14.36; $p < 0.05$) and hamstrings (F[H] = 3.9; $p < 0.05$) results. None serious injury has been produced among the players during the 2-months of the study.

Discussion: We concluded that infrared thermography is a valid, fast and convenient method of preventing soccer injuries. We suggest that this technique could also be applied to monitor and diagnose injuries and to quantify training loads in sports

CARDIAC ADAPTATIONS WITH 6 WEEKS OF EITHER SPRINT INTERVAL OR ENDURANCE EXERCISE TRAINING IN HEALTHY YOUNG HUMANS

RAKOBOWCHUK, M., PROUDFOOT, N., TANGUAY, S., MACDONALD, M.J.

1. UNIVERSITY OF LEEDS, 2. MCMASTER UNIVERSITY

Introduction: A recent study showed improved peripheral vascular adaptations to sprint interval training (SIT) that are similar to those of traditional endurance training (ET) (Rakobowchuk et al., 2008). However, central artery stiffness was not improved with either training paradigm, suggesting limited central vascular or cardiac adaptations. The current study evaluated whether 6-weeks of SIT alters left ventricular (LV) morphology compared with traditional ET.

Methods: Twenty healthy untrained subjects were randomly assigned to a SIT (n=10, 24 ± 1.0 yrs [mean ± SE]) or ET group (n=10, 23 ± 0.7 yrs). The SIT group completed 4-6 x 30s "all-out" efforts (repeated Wingate Tests) separated by 4 minutes of recovery, 3 times/wk. The ET group completed 40-60 minutes of cycling at 65% of their maximal oxygen uptake, 5 d/wk. B-mode echocardiography (GE System FiVe, 2.5 MHz probe) was used to quantify LV morphology, using established guidelines, in all participants on 2 separate days before training and at 48 after the completion of training.

Results: Training improved maximal oxygen uptake to a similar extent in both groups (ET PRE: 40.5±6.6 ml/kg/min, POST: 42.4±6.6 ml/kg/min; SIT PRE: 40.7±6.1 ml/kg/min, POST: 45.0±5.2 ml/kg/min, $p<0.05$). The 2 modes of training resulted in different changes in LV dimensions during supine rest. The ET group showed significant reductions in LV diameter at end systole and a non-significant increase in the interventricular septum at end systole resulting in increased percent fractional shortening (pctFS) (PRE: 31.9 0.58%, POST: 34.2 1.3%, $p=0.015$) and a greater LV ejection fraction (EF) (PRE: 0.68 0.01, POST: 0.71 0.02, $p=0.05$). In contrast, SIT did not alter individual cardiac diameters; but was associated with a small but significant reduction of EF (PRE: 0.70 0.01, POST: 0.67 0.02, $p=0.047$). There was a trend ($p=0.056$) for a group x training interaction in LVmass with mass increasing in the SIT group (PRE:139.2 13.5, POST:151.7 15.1g) and no change in the ET group (PRE:173.7 14.3, POST:171.9 16.0g).

Discussion: Overall, these results suggest unique adaptations of the LV that vary with each training method. Past research has noted small increases in LVmass in sprint trained individuals and following sprint based training (Ricci et al., 1982), however this is the first study to observe this effect when participants were not partaking in additional training (resistance) that may evoke concentric hypertrophy. We also show improved EF and pctFS in the ET group, which may be a functional and not a morphological adaptation due to reduced HR and adaptive hypervolemia.

Supported by NSERC Canada, Canadian Institutes for Health Research.

EXERCISING WITH RESERVE: EXERCISE REGULATION BY PERCEIVED EXERTION IN RELATION TO DURATION OF EXERCISE AND KNOWLEDGE OF ENDPOINT.

SWART, J., LAMBERTS, R.P., LAMBERT, M.I., LAMBERT, E.V., WOOLRICH, R.W., JOHNSTON, S., NOAKES, T.D.

UNIVERSITY OF CAPE TOWN

Introduction: Noakes and colleagues [1] have proposed that the rising RPE produced during exhaustive exercise acts as a protective mechanism during exercise, overriding the conscious desire to increase the exercise intensity if such an increase could threaten homeostasis, either at that moment or sometime in the future. Accordingly, athletes maintain a reserve capacity, presumably to prevent any catastrophic failure of homeostasis.

Methods: We examined the rate of RPE increase during repetitive maximal effort time trials as well as after an intervention which aimed to decrease certainty about the remaining distance of the exercise bout. In addition, we examined the rate of RPE increase during bouts of markedly different duration. Part 1: 12 well-trained, competitive level cyclists completed five 40km time trials. During the final time trial all feedback was withheld until the final kilometre. In addition, to cause confusion about the remaining distance, they were asked to report their RPE at random intervals from 18km to 38km. Part 2: 6 well-trained, recreation level cyclists randomly completed a 5km, 10km, 40km and 100km time trial.

Results: Part 1: Mean ratings of perceived exertion increased during the first 4 trials and decreased during the final trial. The rate of RPE progression increased in linearity during the first four trials and became more conservative in the final trial. These changes were directly related to performance. Part 2: Mean ratings of perceived exertion for longer duration trials (40km, 100km) were lower during the first half of trial duration but matched those of shorter trials in the final 20%.

Conclusions: We showed that the rate of increase in perceived exertion during exercise is not always repeatable, but changes in relation to certainty about the endpoint of exercise as well as the set exercise duration. When subjects were initially unfamiliar with the exercise bout, they chose a perceived exertion strategy that maintained a larger metabolic reserve which was then accessed near the end of the

bout. With increased familiarity with the required exercise task, the RPE strategy became more aggressive, linear and with less metabolic and cardiorespiratory reserve. This was associated with increased performance. Similarly, during exercise bouts of longer duration, subjects started exercise bouts with lower RPE scores and maintained these lower RPE values until the final 20-30% of the exercise bout, after which they increased the RPE to values similar to those recorded during the shorter exercise trials. Subjects therefore maintained a greater metabolic and cardiorespiratory reserve during longer trials.

MUSCLE ACTIVATION PATTERNS IN SHOULDER IMPINGEMENT PATIENTS

STRICKLAND, J., GOSS-SAMPSON, M., WHITE, T.

UNIVERSITY OF GREENWICH

Introduction: Shoulder impingement is one of the most common presentations of shoulder joint problems 1. It appears to be caused by a reduction in the sub-acromial space as the humerus abducts between 60o -120o – the 'painful arc'. Structures between the humeral head and the acromion are thus pinched causing pain and further pathology 2. Shoulder muscle activity can influence this joint space but it is unclear whether this is a cause or effect in impingement patients. This study aimed to observe muscle activation patterns in normal and impingement shoulder patients and determine if there were any significant differences.

Method: 19 adult subjects were asked to perform shoulder abduction in their symptomatic arm and non-symptomatic. 10 of these subjects (age 47.9 ± 11.2) were screened for shoulder impingement, and 9 subjects (age 38.9 ± 14.3) had no history of shoulder pathology. Surface EMG was used to collect data for 6 shoulder muscles (Upper, middle and lower trapezius, serratus anterior, infraspinatus, middle deltoids) which was then filtered and fully rectified. Subjects performed 3 smooth unilateral abduction movements at a cadence of 16 beats of a metronome set at 60bpm, and the mean of their results was recorded. T-tests were used to indicate any statistical significance in the data sets. Significance was set at $P<0.05$.

Results: There was a significant difference in muscle activation with serratus anterior in particular showing a very low level of activation throughout the range when compared to normal shoulder activation patterns (<30%). Middle deltoid recruitment was significantly reduced between 60-90o in the impingement group (30:58%).Trends were noted in other muscles with upper trapezius and infraspinatus activating more rapidly and erratically (63:25%; 60:27% respectively), and lower trapezius with less recruitment (13:30%) in the patient group, although these did not quite reach significance.

Conclusion: There appears to be some interesting alterations in muscle recruitment patterns in impingement shoulder patients when compared against their own unaffected shoulders and the control group. In particular changes in scapula control (serratus anterior and trapezius) and lateral rotation (infraspinatus), which have direct influence on the sub-acromial space, should be noted. It is still not clear whether these alterations are causative or reactionary, but this finding gives a clear indication to the importance of addressing muscle re-education as part of a rehabilitation programme in shoulder impingement patients.

IS-SS05 Sport and cultural identity

SPORT AND THE IDEA OF NORTHERN IRELAND

BAIRNER, A.

LOUGHBOROUGH UNIVERSITY

Since the early 1980s, the socio-cultural significance of sport in Northern Ireland has attracted considerable interest from sociologists, historians and anthropologists. Much of the relevant work focused on the ways in which sport not only reflected but also contributed to the construction and reproduction of competing political identities. Additional published output examined the extent to which sport can be used to help transcend those divisions. Implicit in much of this research was an understanding of the contested nature of Northern Ireland as a political entity which as a consequence of agreement by the Democratic Unionist Party and Sinn Féin to share power is arguably more secure than at any time since the formation of the Northern Ireland state in 1921. This altered political context offers an ideal opportunity to assess in greater depth than ever before the meaning of Northern Ireland in relation to the identity formation of those who live there. This paper examines the ways in which various sports, but in particular association football, have contributed in the past to the idea of Northern Ireland and assesses the potential of sport help consolidate the current constitutional arrangements.

A QUESTION OF REARING TO COMPETITION, DEMOCRACY OR CARE IN EQUESTRIAN SPORTS

HEDENBORG, S.

SPORTS STUDIES

The purpose of this paper is to analyze the rearing of children and young people within equestrian sports in Sweden during the second half of the 20th century. In contemporary times the Swedish Sport Movement, together with schools, is the most important rearing environment for children. However, the actual goal of the rearing, except of course learning a specific sport activity, is more unclear. The question is important as children's sports receive significant financial support from the government. In the contemporary debate on this issue, children's experiences as well as emotions like happiness and sorrow; fellowship and marginalization are presented as outcomes

of children's sports activities. In recent times especially the competitative rearing ambitions have been criticized whereas goals like participation for all have been emphasized as the primer aim. Other questions have been the role of parents and children's inclination and discomfort in connection to sports.

Previous research on football for children and young people has demonstrated that political intentions emphasizing sports for all and a rearing focused on democratic values has justified governmental financial support to children's and young people's sports activities. Despite this, children within the football associations are often raised with values connected to competition and marginalization (Peterson 1993). Furthermore, children's sports environment is very authoritarian (Redelius 2002). Rearing within the sports movement is also a question of gender. Generally sports has been connected to men and masculine values (Olofsson 1989; Hjelm 2004; Larsson 2005; Hedenborg 2008). A study of rearing activities within football has demonstrated that quite young boys are met by a masculinity constructed in opposition to homosexuality and femininity (Fundberg 2003). Whether the same values can be, and have been, seen in equestrian sports is questioned in this paper. Furthermore it is argued that the target of rearing can be connected to gender. A question raised is whether the target of rearing can explain the feminizing process within equestrian sports.

Annual reports from one of the equestrian organizations (Ridfrämjandet), interviews with two persons who have been working with education within this organization and letters from children sent to a children's magazine are used as source material. The latter is of specific interest as this source material will reflect children's own experiences and view of the rearing aims.

NO SENSE OF PLACE? TRANSNATIONALITY AND IDENTITY IN FOOTBALL

HOGNESTAD, H.

TELEMARK UNIVERSITY COLLEGE

This paper discusses globalization and perceptions of cultural differences in football. The consumption of football and the experience of the game's social and physical places (stadiums, streets, pubs) will be scrutinized with examples drawn from studies in Northern Europe.

Debates around globalization in football is further highlighted through moral and political calls for the protection of "our" (national) talents and restrictions on the number of "foreign" footballers. These issues are particularly evident in debates which seeks to promote the interests of national team football against an increasingly commodified international club football.

In this paper I shall particularly discuss the ways in which football supporters apply notions of 'who we are' and 'who we are not' within the cultural complexity of contemporary football. The paper also seeks to delve into the issue of how these orientations can be linked to more general social, racial and cultural issues.

IS-BC04 Genomics and Exercise: Signals and Mechanisms of Training Adaptation, a Systems Biology Approach (ACSM Exchange Symposium)

A SYSTEMS BIOLOGY APPROACH TO DECIPHERING THE MOLECULAR BASIS FOR AEROBIC ADAPTATION IN HUMANS

TIMMONS, J.A.

RVC, UNIVERSITY OF LONDON

Complex organisms have evolved to incorporate the benefits of the steep thermodynamic gradient afforded by atmospheric oxygen and to deal with the obligatory reactive nature of oxygen chemistry. This implies that the link between aerobic capacity and disease may reflect gene-environment interactions that have evolved to regulate the safe transport or consumption of molecular oxygen for the purpose of energy transfer. This may also explain why low aerobic capacity (2max) is one of the strongest risk factors for development of cardiovascular disease and premature death in mammals. Exercise, the sole strategy for increasing aerobic capacity in humans, is ineffective in a significant number of people(1). The molecular governors of a low or high propensity for aerobic capacity adaptation are unknown, and population genetics alone has not easily resolved the genetic variants that quantitatively contribute to cardiorespiratory adaptation. We previously produced the first protein coding genome-wide analysis of human muscle adapting to aerobic training(2). From this we identified that molecular approaches (e.g. KO mice) involving single-gene in vivo manipulations demonstrate little genuine connection with the complex physiological process we noted in humans. To further explore our observations we developed a new strategy; combining the power of natural biological variation, across four independent human studies, with gene-chip profiling (n=120) to facilitate molecular predictor analysis. A 29 gene transcript signature, established at baseline in young sedentary subjects, was able to blindly predict the magnitude of aerobic adaptation in young active subjects, and in middle-aged subjects with metabolic syndrome and this led to the identification of genetic variation in 6 genes in the HERITAGE study population which associated with gains in aerobic capacity. We verified that a pro-angiogenic network activation associated with the magnitude of aerobic adaptation in humans (and in rats artificially selected for a low or high response to aerobic training). Parallel protein coding RNA and microRNA (miRNA) analysis with independent bioinformatics identified transcription factors that coordinate muscle adaptation, while conservation of gene-network activation across physiological states and species underscores the robustness of our analysis. The utility of expression profiling to focus genome-wide association studies is thus exemplified by our study, while the ability to predict aerobic adaptation in humans, has promise for facilitating personalized medicine and defining therapeutic targets for enhancing aerobic capacity.

EXERCISE GENOMICS: RESULTS FROM THE HERITAGE FAMILY STUDY

BOUCHARD, C.

PENNINGTON BIOMEDICAL RESEARCH CENTER

The focus of this presentation will be on the complex network of genes and DNA sequence differences that contribute to human variation in cardiorespiratory fitness as assessed by maximal oxygen uptake (VO2 max) and in the changes brought about by exercise training in VO2 max and risk factors for diabetes and cardiovascular disease. Results of the HERITAGE Family Study indicate that, among sedentary adults, VO2 max adjusted for age, sex, ethnicity, body mass and body composition is characterized by an heritable component of the order of 50%. The response of VO2 max to training, adjusted for baseline level, age, sex and ethnicity, is influenced by a genetic component of the same magnitude. However, there is no correlation between the sedentary level of VO2 max and its trainability, suggesting that different gene networks and sequence variants regulate them. The heterogeneity of responses to training is considerable, with a range from about fourfold to tenfold when comparing the lowest to the highest responders. Four approaches have been used to identify the genes that are contributing to human variation in sedentary VO2 max, its trainability and training-induced changes in risk factors: candidate genes, gene expression arrays, genome scans with microsatellite markers, and genome-wide association studies with panels of single nucleotide polymorphisms (SNPs). Responsiveness to exercise-training among HERITAGE subjects has been associated with multiple genes including TTN, KIF5B, CREB1, SLC4A5 and FHL1. DNA SNPs in these 5 genes have been associated with differences in training-induced changes in hemodynamic and metabolic endophenotypes. The broader network of exercise responsiveness genes as revealed by HERITAGE will be defined. The role of FHL1 genotypes on the changes brought about by regular exercise in insulin and glucose metabolism will be highlighted. The usefulness of exercise genomics for applications in public health and physical performance domains will be discussed.

OP-ST07 Sports 7

PREDICTION OF CROSS-COUNTRY SKI SEASON PERFORMANCE BASED ON A LINEAR REGRESSION MODEL OF LABORATORY ROLLER SKI CAPACITY AND VO2MAX TEST

NAEF, N., STEINER, T., MÜLLER, B., WEHRLIN, J.P.

SWISS FEDERAL INSTITUTE OF SPORTS, MAGGLINGEN, SWITZERLAND

Introduction: Cross-country (XC) ski-specific testing is used to support elite athletes regarding their training control as well as to predict performance of competitive ski season (Alsobrook & Heil, 2009, Staib et al., 2000). The purpose of this study was to investigate the relationship between the results of two different laboratory preseason roller ski tests and the XC ski performance of the following season as well as its predictability with a linear regression model.

Methods: In October 2008, 14 male XC skiers of the Swiss National U20 (n=5), U23 (n=2) and Elite (n=7) Distance Ski Team completed two laboratory roller ski tests on a large motor-driven treadmill. Athletes performed a maximal diagonal stride test to measure VO2max. 24 hours later they carried out a maximal double poling capacity test with self selected speed during three stages of eight minutes (5 min at 3° inclination and 3 min at 5° inclination) to establish maximal possible distance. XC ski season performance was ranked by the 4th XC ski distance International Ski Federation (FIS) points list 2008/2009. Spearmen correlation analyses and multiple linear regression models were applied.

Results: Athletes achieved a mean total distance of 5299.3 ± 460.5m, a VO2max of 77.4 ± 4.6 ml/min/kg and mean FIS Points of 59.7 ± 44.1 (range = 1.2 - 130.5). There was a negative correlation between distance and FIS points as well as VO2max and FIS points ($r = -0.832$; $p < 0.001$ and $r = -0.510$; $p = 0.062$, respectively). Age was significantly correlated to FIS points ($r2 = -0.638$; $p = 0.014$). The best linear regression model to predict FIS points was: FIS points = - 0.069 * distance [m] - 2.897 * VO2max [ml/min/kg] + 650.95 with a mean residual of 15.6 ± 9.2 points. Correlation between XC ski performance and the linear regression model was significantly ($r2 = 0.790$, $p < 0.001$).

Discussion and Conclusion

These findings suggest that distance achieved during the capacity test and VO2max are important determinants of the following XC ski season performance. Our linear regression model based on a ski-specific laboratory test is highly correlated with seasonal performance (FIS). We suggest that this model is a useful tool to predict XC ski performance of the following winter season, in spite of the long time frame and possible confounding factors (health problems, ski preparation, race tactic, etc).

THE RELATIONSHIP BETWEEN OXYGEN EXTRACTION IN THE ARMS AND LEGS TO FORCE AND EXERCISE INTENSITY IN DIAGONAL SKIING

BJÖRKLUND, G., STÖGGL, T., CARLSSON, L., DOVRÉN, L., HOLMBERG, H.C.

MID-SWEDEN UNIVERSITY

Introduction:

Diagonal skiing (DIA) is the main classical cross-country technique used when skiing uphill. Two interesting findings when examining this technique at submaximal workloads have been that 1) O2 extraction was lower in the arms than the legs (Calbet et al., 2005) and 2) lactate oxidation mainly occurred in the leg muscles simultaneously with a high lactate production in the arms (Van Hall et al., 2003). At

present no data have described how these findings may be associated with force generation and the muscle activity measured by electromyography (EMG). Thus, the aims of this study were to examine i) the interaction between physiological and biomechanical variables and ii) the effect of changes in submaximal exercise intensities in diagonal skiing.

Methods:

Eleven elite XC skiers (age 22±3yr; VO2max 69±3 mL/kg/min, obtained during DIA on a treadmill) performed a protocol of 3 min at 90% followed by 6 min at 70% of VO2max DIA. Cardiorespiratory data were collected continuously, along with determination of blood gases and metabolites from a. femoralis, v. femoralis and v. subclavia. Pole and foot forces (Pedar, Mobile 100Hz) and EMG data from six lower and upper body muscles (Noraxon, 3000 Hz) were collected. Changes to variables between 90% and 70% of VO2max were analyzed using paired sample t-tests. Pearson correlations were used to evaluate the relationships between variables. α was set to 0.05.

Results:

The O2 extraction was higher for legs than arms at both exercise intensities ($p<0.05$). The arms O2 extraction decreased more than that of the legs when intensity decreased ($p<0.01$). Leg and pole peak forces and muscle activity increased with intensity ($p<0.01$), whereas the impulses of forces and the ratio between the arm and leg force remained constant. O2 extraction was negatively associated with iEMG activity in % of MVC at both intensities ($r=-0.56$ to -0.91, $p<0.05$ to $p<0.001$). The lactate a-v difference in the arms was associated with the leg impulses at both intensities ($r=-0.53$ and -0.57, $p<0.05$) and with a cycle rate at 70 % of VO2max ($r=0.77$, $p<0.01$).

Discussion:

A decreased relative use of the arms and legs' MVC at a given % of VO2max decreases O2 extraction. The difference in O2 extraction between the arms and legs increased at decreased exercise intensities, mainly due to decreased arm O2 extraction despite similar changes in muscle activity. A high leg impulse decreases lactate occurrence in the arms, regardless of exercise intensity, whereas a low cycle rate is important only during medium intensity DIA.

ENDURANCE TRAINING AND SPRINT PERFORMANCE IN ELITE JUNIOR CROSS-COUNTRY SKIERS

SANDBAKK, Ø., WELDE, B., HOLMBERG, H.C.

NORTH-TROENDELAG UNIVERSITY COLLEGE, DEP. OF SPORT AND PHYSICAL EDUCATION, ROESTAD, N-7600 LEVANGER, NORWAY

Introduction: Sprint races in modern cross-country (XC) skiing have a shorter racing time, as well as a relatively flat terrain profile, when compared to traditional races. Several studies have thus suggested that maximal speed is the most important performance predictor (e.g. Stöggl et al., 2007). However, the energy release for comparable racing times in other sports is reported to be 70-85% aerobic (Gastin, 2001). The present study therefore investigated the importance of aerobic capacity in sprint performance. The effects of a major change in training stimuli, due to increased emphasis on high-speed moderate intensive endurance training upon sprint performance, maximal O2-uptake (VO2max) and O2-uptake at the ventilatory threshold (VO2VT) were also examined. Methods: Fifteen (10 males and 5 females) elite junior XC skiers (age 17.4±0.5 yr, VO2max 68±6 ml kg-1 min-1) participated in this study. After an eight week baseline training period, all subjects performed a freestyle 1.5 km sprint time-trial on roller skis. In addition, VO2max and VO2VT were measured in the laboratory. Thereafter, an eight week intervention training period was performed. Subjects were split into a control group (CG, n=8) and an intervention group (IG, n=7). The IG increased their training at intensities near the ventilatory threshold, emphasizing level and mixed terrain in order to induce more high-speed training, while the CG continued their traditional polarized training model with 70-80% slow distance training and the remainder as high-intensity interval training. After the intervention training period the sprint race and tests on VO2max and VO2VT, were rerun. Results: Close relationships were found between VO2max ($r = -0.79$, $p<0.01$) and VO2VT ($r = -0.67$, $p<0.01$) and sprint performance. The mean sprint time in all athletes was 3:36±0:19 min in the pre-test. The IG improved sprint performance by 4.5±2.9% ($p<0.01$), VO2max by 3.9±1.9% ($p<0.01$) and VO2VT by 9.9±3.1% ($p<0.01$) from pre- to post-test. No significant changes were found in the CG. Discussion: Our findings suggest an association between sprint performance and aerobic capacity. The improvements in the IG are potentially related to the major change in training stimuli and demonstrate the effects of training at these moderate intensities, as well as the importance of training periodization. Additionally, some of the improvements might have been induced by the high speed rather than the effects of the exercise intensity.

ANTHROPOMETRY AS A PREDICTOR OF SPRINT SKIING PERFORMANCE

ENQVIST, J., HOLMBERG, H.C., STÖGGL, T.,3

1. SWEDISH WINTER SPORTS RESEARCH CENTRE, 2. DEPARTMENT OF SPORT SCIENCE AND KINESIOLOGY,UNIVERSITY OF SALZBURG,SALZBURG,AUSTRIA,3.CHRISTIAN DOPPLER LABORATORY"BIOMECHANICS IN SKIING",SALZBURG,AUSTRIA

Introduction: Anthropometric measurements have been used in sports for finding performance limiting factors (Reilly et al. 2000; Drinkwater et al. 2008). Studies concerning relationships between anthropometric characteristics and performance in XC skiing are limited (Bergh 1987; Larsson and Henriksson-Larsen 2008). The aims of the present study were to examine possible relationships between anthropometric values and sprint skiing performance. Methods: Fourteen elite sprint skiers (mean age 26.4±4.8 yrs; body weight 76.7±5.4kg; body height 180.4±4.6cm; VO2max 5.2±0.5 l•min-1, volunteered to participate in the study. Subjects were examined with DXA to determine body composition and body dimensions (Lunar iDXA, General Electric Company, Madison, USA) and performed two incremental maximal sprint tests using the double poling (DP) and the V2 skating techniques, both performed with roller skis on a treadmill. Results: BMIlean displayed the highest positive relationships towards DP maximal speed ($r=0.80$, $p<0.001$) of all the measured variables. Body weight, total lean mass and total trunk mass were all positively correlated to DP performance ($r=0.57$; $p<0.05$; $r=0.69$, $p<0.01$; $r=0.53$, $p<0.05$). Absolute and relative (%trunk mass) lean mass of the trunk was positively related to DP maximal speed (abs. value $r=0.75$; $p<0.01$; rel. value $r=0.550$, $p<0.05$). The ratio between trunk mass to trunk length and the ratio between trunk mass and the mass of the head and

the neck were positively related to DP maximal speed (r=0.58, p<0.05; r=0.69, p<0.01). None of the measured anthropometrical variables were significantly associated with V2 skating maximal speed. Discussion: The findings in this study agree with Bergh (1987), suggesting that heavier skiers are favoured over all parts of a racing course except for steep uphills. However, this aspect was only valid in the current study in DP. Based on the results, we suggest that skiers should aim to achieve an optimal body composition that has a high percentage of lean mass and low fat mass, with a particular focus on high trunk mass in order to have the proper body composition for DP sprint performance. No anthropometrical predictors of performance were found for the V2 skating technique, suggesting that high maximal speed in that technique is not associated with body morphology. The results suggest that maximal speed in DP and V2 skating is not determined by genetic body dimensions but, particularly for DP, by trainable factors such as total mass, muscle mass and body fat.

QUALITY OF GRIP WAXING AND THE FORCE PRODUCTION IN CLASSICAL SKIING

LINNAMO, V., PIIRAINEN, J., VÄHÄSÖYRINKI, P., KOMI, P.

UNIVERSITY OF JYVÄSKYLÄ, VUOKATTI SPORTS INSTITUTE

Introduction: Horizontal force during the kick phase in classical skiing is depending on the GRIP waxing quality of the ski (Komi 1987). The effect of waxing is likely to be even more substantial in uphill skiing with shorter gliding phase. The purpose of the present study was to examine the effects of waxing on the force production and skiing speed in steep uphill classical skiing. In addition it was examined if the waxing properties affect the force production and gliding properties when measured using a novel ski tester.

Methods

7 experienced male skiers (age 21.7 + 5.1 years) skied 11˚ uphill with maximal speed with three different waxing conditions (slippery, medium grip and good grip). Vertical and horizontal forces of both skis and poles were measured with a 12m long force plate system. After the subject had skied over the force plates the ski was attached to a ski tester (Linnamo et al. 2008). The pressure against the force plates was adjusted to be 60% of the body weight (BW) for each subject. In addition, gliding phase was measured with 150% BW. All the measurements took place in indoor Ski Tunnel in Vuokatti Sports Institute.

Results: No major differences were observed in maximal pole forces or in maximal vertical ski forces while the maximal horizontal force during kick phase increased significantly (P<.01) as a result of better grip (slippery 154 + 27 N, medium grip 168 + 53 N, good grip 279 + 66 N). This led to a significant (P<.01) increase in skiing speed (slippery 3.5 + 0.4 m/s, medium grip 4.1 + 0.3 m/s, good grip 4.5 + m/s). Ski tester with 60% BW showed no significant differences in maximal vertical force but maximal horizontal force was significantly higher (P<.05) in good grip condition than in slippery. Horizontal force in the gliding phase was similar in 60% BW between different waxing conditions but with 150% BW it increased significantly (P<.01) from slippery to good grip.

Discussion: This study showed that in a steep uphill (11˚) the horizontal ski forces and skiing speed are remarkably improved with better grip wax conditions. While the skiing speed decreased with slippery waxing the pole forces remained similar in all conditions. This suggests that the horizontal ski force loss cannot be compensated with pole forces when skiing with maximal speed. As expected the maximal skiing speed in the present study (4.5 m/s) was lower than earlier observed (5.6 m/s) in 2.5˚ uphill skiing (Vähäsöyrinki et al 2008). Due to steep uphill the gliding phase was almost non existent thus slowing down the speed. On the other hand even better grip did not affect the gliding properties as was the case with 150% BW in ski simulator. During kicking phase the ski simulator was able to differentiate the horizontal forces between waxing conditions even with only 60% BW.

AUTONOMIC RECOVERY DURING HIGH TRAINING LOADS IN FEMALE WORLD-CLASS BIATHLON ATHLETES

EMANUELSEN, E., SANDBAKK, Ø., WELDE, B., MORK, P.J.

NORTH-TROENDELAG UNIVERSITY COLLEGE, NORWAY

INTRODUCTION: World class endurance athletes endure extremely high training loads (frequency, duration and intensity) to achieve a maximal adaptive effect. Incomplete recovery can, however, lead to stress-related side-effects indicated by autonomic imbalance. Heart rate variability (HRV) is an established, noninvasive tool to investigate autonomic balance. At present, there is a lack of information regarding autonomic recovery during hard training periods in elite female endurance athletes. The aim of this present study was to investigate the relation between HRV, training load, and self reported form and fatigue during 3-week of competitive training in world-class female biathlon skiers. METHODS: Seven female world class biathlon skiers (25.6 +- 3.2 yr, 172.3 +- 3.4 cm, 62.5 +- 7.3 kg, 63.8 +- 2.6 ml•min-1•kg-1), all members of the Norwegian biathlon team, including World Cup and World Championship medal winners, participated in the study. HRV, training load, and self reported form and fatigue were recorded on a daily basis during a 3-week competitive training period. HRV was recorded with a Polar Heart Rate Monitor (Polar RS800) each morning for 5 minutes in the supine position. Low intensity (LIT), moderate intensity (MIT), and high intensity (HIT) endurance training were quantified by HR recordings during each training session. Overall training load (TRIMP) was calculated by multiplying the accumulated duration spent in each intensity zone by 1, 2, and 3 for the LIT, MIT and HIT, respectively. Self reported fatigue was scored on a 1 to 6 point scale (1 = no fatigue; 6 = maximal fatigued), and self reported form from a 4 to -4 point scale (4 = extremely good form/light feeling; -4 = extreme bad form/heavy feeling), after every training session. RESULTS: Preliminary analysis revealed no general relation between HRV, TRIMP, and self-reported fatigue and form; however, the –inter-individual variation was substantial. For some athletes, self reports of fatigue and form showed a time lag (1-4 days) to indices autonomic recovery, e.g., indices of improved or reduced form was preceded by reduced or increased HRV. However, variation in form and fatigue was small and the overall impression was that most athletes obtained autonomic recovery even after two succeeding days with competition. DISCUSSION: In general, world-class female biathlon athletes' shows fast autonomic recovery during a hard training and competition period, despite extremely high training loads. An overnight rest seems to be sufficient to recover from two train-

ing sessions and 2-4 hrs daily training. However, the inter-individual variation is substantial and recordings of HRV may be a useful tool for some athletes to monitor autonomic recovery during periods with high training loads.

ACUTE EFFECTS OF A LOW-STRETCHING STATIC PROTOCOL IN THE UPPER BODY FORCE PRODUCTION

PEZARAT-CORREIA, P., LEONE, D., VALAMATOS, M.J., FERNANDES, O.

FACULTY OF HUMAN KINETICS, TECHNICAL UNIVERSITY OF LISBON

Introduction: Previous research has shown that static stretching in the warm-up can decrease several muscular performance variables. For example, Kokkonen et al. (1998) showed that 1 repetition maximum (1RM) of knee flexion and extension was decreased by previous static stretching in some muscle groups of the lower limbs. Fowles et al. (2000) found that maximal voluntary isometric contraction (MVC) and neuromuscular activity of the triceps surae muscle were impaired immediately after repeated static stretching. However, the vast majority of studies have examined only the effects of this stretching routine on lower-body performance. The purpose of this study was to investigate the acute effects of a low-stretching static protocol on maximal isometric force, time to maximal isometric force, rate of force development, and EMG amplitude of main agonist muscles acting on the bench press exercise.

Methods: Twenty participants were randomly allocated into two equivalent groups: no stretch (NS) and static stretch (SS). The MVC on the bench press exercise was measured before and after (immediately, 10 min, 20 min, and 30 min) the static stretching, and nonstretching. The average amplitude of the surface EMG (AvgEMG) of the pectoralis major, long and lateral heads of the triceps brachii was measured during MVC.

Results: There was a significant decrease (p=0.001) in the maximal isometric force from the pre to the post-stretching in the SS group. This decrease was nearly 6%, with an initial average value of 895.7 ± 232.1N and achieving 839.9 ± 213.8N immediately after stretching. In this group, there were no significant differences in the time to maximal isometric force and rate of force development of the three investigated muscles between the pre to the post-stretching. Significant decreases in the AvgEMG of the three muscles were found (p<.05) from the pre to the post-stretching in the SS group. No significant differences were found in the control group (NS) in the force or in the EMG parameters between the pre and the post-stretching. Force did not remain significantly decreased for 30 min in both groups.

Discussion: It appears that an acute bout of static stretching impaired the force output in the pectoralis major and in the long and lateral heads of the triceps brachii. The results suggest an association between stretch-induced changes in muscular activation and maximal isometric force in an earlier phase.

EFFECTS OF HEART RATE BASED RECOVERY PERIOD ON HORMONAL AND NEUROMUSCULAR RESPONSES DURING STRENGTH TRAINING

PIIRAINEN, J., NISSILÄ, J., TANSKANEN, M., LINNAMO, V.

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: One of the main objectives in strength training is to increase the amount of muscle mass. To obtain this, anabolic hormones such as testosterone and growth hormone play a key role by increasing protein synthesis (1) and thus causing hypertrophic responses in muscles. Shorter recovery time between sets may cause higher anabolic hormone response (2), but it is unclear what would be the optimal recovery time. Purpose of this study was to evaluate the effect of heart rate based recovery time in hormonal and strength responses among men and woman.

METHODS: Totally 35 male and female subject (male n=21, 31±9 years; female n=14, 32±10 years) participated in this study. Subjects were divided four different groups (FT80M; male study group, controlM; male control, FT80F; female study group, controlF; female control group). Subjects trained three times per week during a seven week training period. The recovery time between the sets in the FT80 group was based on to the heart rate monitor calculation (Polar FT80) while the control group used constant two minute recovery after each set. Basal concentrations of serum total testosterone, growth hormone and cortisol were measured in the beginning (0 week) and after the training session (7 weeks). MVC was measured during 1RM concentric knee extension using knee extensor dynamometer and 10RM loads were measured in gym in the beginning and at the end of the study period.

RESULTS: Recovery times of 50-55 seconds in FT80 group were significantly lower (p<.001) compared to the control group (120 seconds) during the entire period. Testosterone levels increased significantly after the training both in FT80M (22.8±15.3%, p<.001) and FT80F (52.6±23.4%, p<.05), while no significant changes were observed in controls. No significant changes were observed in cortisol levels. Training induced increment in 10RM among FT80M (63.3±33.6%, p<.001) was higher (p<.05) than in controlM (32.7±21.3%, p<.001), while in women the increment was the same between groups (n.s.).

DISCUSSION: These results suggest that individual heart rate based recovery time between the sets may be more optimal in hypertrophy type strength training than standard recovery time. In addition, the results confirm that high intensity strength training increase the anabolic hormone levels (2). Unchanged cortisol levels could suggest that the training did not cause overtraining state and therefore the training intensity was not too strenuous. Also higher 10RM increment among FT80M supports the conclusion about the more optimal training intensity based on the heart rate dependent recovery time.

BRIEF FORCE PULSES: THE RELATIONSHIP BETWEEN THE PEAK FORCE AND RATE OF FORCE DEVELOPMENT

JARIC, S., SUZOVIC, D., NEDELJKOVIC, A.

UNIVERSITY OF BELGRADE (BELGRADE, SERBIA), UNIVERSITY OF DELAWARE (NEWARK, USA)

Introduction: While the standard strength tests assess the ability to exert high force of sustained maximum isometric and isotonic contractions, a number of important functional movements are based on brief 'force pulses' exerted in either discrete (e.g., postural corrections, pointing) or repetitive movements (walking, running, cycling). Therefore, in addition of requiring high forces that may be either painful or inappropriate for some populations, the standard strength tests may not capture the activation pattern of brief muscular actions. The aim of this study was to evaluate the relationships between the peak force and the rate of force development and relaxation of the brief force pulses (BFP) as candidate for a novel test of neuromuscular function.

Methods

Within the first experiment, 12 participants performed consecutive series of 12 isometric BFP (i.e., a rapid exertion of force to a prescribed level followed by rapid relaxation) targeting 30%, 50% and 70% of MVC both within-day and across days. Individual BFP provided the peak force (PF) and the rates of force development (RFD) and relaxation (RFR). The data from each series were, thereafter, presented on RFD-PF and RFR-PF graphs and the linear regression was assessed. These data were used for the assessment of the within-day and between-day reliability through the intra-class correlation coefficients (ICC) and coefficients of variation (CV%). Within the second experiment, additional 36 participants performed the same test of the knee flexors and extensors, and elbow flexors and extensors. These data served for the general assessment of the RFD-PF and RFR-PF relationship, as well as for a comparison of the variables obtained from different muscle groups.

Results: The first experiment revealed moderate to high within-day reliability (i.e., ICC, range 0.71-0.98; CV%, range 1.8-141.5) as well as moderate to high between-day reliability (i.e., ICC, range 0.58-0.92; CV%, range 4.1-205.8) of the slopes and intercepts of the PF-RFD and PF-RFR relationship. The second experiment revealed similar slopes across the tested groups, while the intercepts were either a relatively low or close to zero. PF-RFD and PF-RFR slopes also moderately correlated. When the data of different muscle groups were related, the slopes moderately correlated, but not the intercepts. Of utmost importance, however, could be exceptionally high correlations.

Discussion: In general, the obtained results suggest both invariant and subject specific force-time profiles of BFP across a range of exerted forces. Of particular importance for future BFP consideration could be an apparent functional importance of the obtained slopes (e.g., discerning 'strong individuals' from 'quick ones'), simplicity (single variable could be the outcome), generalizability across muscle groups, and low level of exerted forces. Therefore, although the external validity remains to be examined, BFP could be a test complementary to the standard strength tests.

INTERSESSION RELIABILITY OF VERTICAL JUMP HEIGHT

SØRENSEN, H., IVERSEN, K.

UNIVERSITY OF AARHUS

Introduction: The usefulness of measurements in research depends on the extent to which the researcher can rely on data as accurate and meaningful indicators of a behavior. In short, the measurements have to be reliable and valid (Portney and Watkins, 2008).

The vertical countermovement jump (CMJ) is often used as a physical performance test. Researchers routinely seek to enhance the reliability of the CMJ height measurement by having subjects perform a number of jumps, typically 3 or 5, and then using either the best or the average for further analyses. However, studies show that there does not exist a consistent protocol for either the number of jumps or whether to use best of or average (e.g. Bazett-Jones et al., 2008, Vanezis and Lees, 2005, Hamilton, 2008). The purpose of this study is to investigate how the number of jumps and the use of best of or average affect the reliability of the CMJ measurements.

Methods: Twenty-two males (25.2 +/- 1.95 years; 1.81 +/- 0.06 meters; 75.9 +/- 6.38 kg [mean +/- SD]) went through the same programme twice (test and retest) with one week in between. The programme started with five minutes warm-up on a cycle ergometer followed immediately by 10 maximal CMJs on a force plate with one minute rest before each jump. From the data, 4 series of 10 test-retest intraclass correlation coefficients (ICC) were calculated. In two series, A and B, jump height was calculated from the vertical impulse, while jump height in the other two series (C+D) was calculated from flight time. The first ICC in each series (A-D) was calculated from the first jump in test and retest. The second ICC in series A+C was calculated from the average of the two first jumps in test and retest, and in series B+D from the best of the two first jumps in test and retest. The same procedure was used for the third ICC and so on until the tenth ICC where all the 10 jumps from test and retest were used in the ICC calculations.

Results: The series A, which was calculated from the vertical impulse and using the average, gave the following ICCs: 1 jump = 0.74; 2 jumps = 0.82; 3 jumps = 0.86; 10 jumps = 0.91. The series B, C and D had lower ICCs and in that order.

Discussion: The results showed three things: (1) It is more reliable to use vertical impulse than flight time, (2) it is more reliable to use average than best of, and (3) ICC increased steeply through the first three jumps and then just slightly. Therefore, when using the CMJ as a physical performance test, one should use vertical impulse and average of at least 3 jumps.

A COMPARISON OF SUCCESSFUL AND UNSUCCESSFUL ATTEMPTS IN 1 RM BENCH PRESS.

VAN DEN TILLAAR, R., ETTEMA, G.

1. SOGN AND FJORDANE UNIVERSITY COLLEGE, 2. RESEARCH CENTRE FOR SPORT, HEALTH AND HUMAN DEVELOPMENT, PORTUGAL, 3. NTNU

Introduction: One of the most popular exercises in strength training for the upper body is bench press. The movement consists of different periods. The sticking period is probably the weakest link in the upward movement and is probably the period at which an attempt will be successful or not. In maximal lifting, understanding of the causes of this sticking period and its effects could help to enhance the training methods. Therefore the purpose of this study was to compare the differences in EMG and kinematics between successful and unsuccessful attempts in bench press at 1RM in recreational weight-training athletes with special attention to the sticking period.

Methods: Eleven male subjects (age 21.9 ± 1.8 yr, mass 80.0 ± 11.2 kg, height 1.79 ± 0.08 m.) with at least one year of bench press training experience participated in this study. The subjects performed attempts at 1RM and 1RM + 2.5kg in bench-press where the kinematics: acceleration, velocity, vertical and horizontal height of the bar, and joint angles were measured and calculated using a 3D motion capture system. EMG was measured for the triceps brachii, the anterior deltoid, the sternal portion of the pectoralis major and the biceps brachii and averaged in 3 periods (pre-sticking, sticking and post sticking period). One successful attempt and one unsuccessful attempt were used for analysis.

Results: The subjects lifted at 1RM 97.73 kg ± 16.3 kg, and unsuccessful attempts were on average at 100.23 kg ± 15.8 kg. Significant differences ($p<0.05$) were found between successful and unsuccessful attempts for the following variables: peak acceleration (2.84 vs. 2.41 m/s2); peak velocity in the upward movement (0.24 vs. 0.19 m/s); vertical barbell height (12 vs. 8 cm); moment arm about the elbow joint and joint angles during at the occurrence of minimal velocity. Both attempts showed the same sticking period, but only in 4 of the 11 subjects failure occurred during that period. The main differences in the kinematics occurred during the sticking period, which was caused by the increased mass. The muscle activity showed the same pattern in both attempts and only differed during the start of the upward movement of the lift.

Discussion: The findings of the current study were in line with Elliott et al. (1989). The difference in success or failure in bench press is not related to a specific time period in which velocity reduces (sticking period). Only a few subjects stopped their attempt during the sticking period. The period started (0.2s) and ended (1.0s) at the same time in both attempts. Total failure often happens after new acceleration, i.e., after the sticking period. This indicates that the sticking period is not related to the mechanism that determines if an attempt will be successful or not. Failure occurs in a sticking region, a poor mechanical force region as indicated by the different external moment arm on the elbow.

NEURAL ADAPTATIONS TO ECCENTRIC STRENGTH TRAINING

EKBLOM, M.M., WELIN, L., THORSTENSSON, A.

SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES AND , KAROLINSKA INSTITUTET

Introduction: The ability to voluntarily activate muscles varies between muscle groups with plantar flexors and knee extensors typically showing sub-optimal activation levels despite maximal voluntary effort. While eccentric strength training has been shown to enhance neural activation of these muscle groups, the neural mechanisms are still unknown. For isometric muscle actions improvements in neural activation have been suggested to occur via e.g. increased central motor drive, elevated motoneurone excitability and reduced presynaptic inhibition of Ia-afferents (Aagard et al., 2002). Since dynamic and isometric actions receive different afferent inputs, the adaptive mechanisms with strength training might also differ. The aim of this study was to investigate if, and via what mechanisms, eccentric strength training of the plantar flexor muscles would affect neural activation during maximal voluntary eccentric and concentric muscle actions.

Methods: Eighteen healthy subjects were randomized into an eccentric strength training group (N = 8) or a passive control group (N = 10). Training consisted of 15 sessions of eccentric plantar flexor exercise over a 5-week period. During pre- and post-training testing, subjects were lying prone with knees extended and their right foot attached to a foot plate controlled by an isokinetic torque motor. Dynamic plantar flexor strength was measured and neural activation was calculated using the twitch interpolation technique. The Soleus H-reflex was used to assess presynaptic inhibition and the Soleus V-wave to test for both changes in presynaptic inhibition and changes in supraspinal inputs to the motoneurone pool. H-reflexes, V-waves, M-waves and twitches were evoked as the foot was moved through an angle of 90◦ during passive ankle rotations (Hmax and Mmax) and during maximal voluntary concentric and eccentric plantar flexion (Hsup, V-wave, and Msup).

Results: Training induced significant improvements in plantar flexor strength and tendencies ($p=0.058$) towards an increase in neural activation during both concentric and eccentric maximal voluntary actions. SOL Hmax/Mmax and Hsup/Msup ratios remained unchanged after training, whereas the Soleus V/Msup ratio was increased during both concentric and eccentric contractions after training. No change was seen in the control group for any of the parameters.

Discussion: The enhanced voluntary strength could be attributed partly to an increase in voluntary activation induced by eccentric training. Since the Hmax /Mmax and Hsup/Msup ratios remained unchanged, the increase in activation cannot be ascribed to decreased presynaptic inhibition. The increased V/Msup ratio for both action types indicate, however, that increased voluntary drive from supraspinal centers and modulation in afferents other than Ia:s, may have contributed to such an increase in voluntary activation.

HUMAN SKELETAL MUSCLE INTRAMYOFIBRILLAR GLYCOGEN IS DECREASED AFTER 14 DAYS OF IMMOBILISATION IN YOUNG AND OLD MEN

NIELSEN, J., SUETTA, C., HVID, L., SCHRØDER, H.D., ØRTENBLAD, N.

UNIVERSITY OF SOUTHERN DENMARK

Introduction: The high magnification of transmission electron microscope (TEM) allows for a visualisation of skeletal muscle subcellular arrangement of structures and inclusions. This has revealed at least three populations of glycogen in humans (Marchand et al. 2002): (1) a major population located in the intermyofibrillar space surrounding the myofibrils in close proximity to sarcoplasmic reticulum and mitochondria (75-85% of total glycogen). (2) A minor population in the intramyofibrillar space, where glycogen particles are located be-

tween the contractile filaments often in the I-band (10-20% of total glycogen). And (3) also a minor population is located in the subsarcolemmal space just beneath the sarcolemma together with e.g. nuclei, mitochondria, golgi complex and lysosomes (5-20% of total glycogen). Their individual roles in muscle function remain today elusive.

Method

In this study 11 young (24 ± 0.5 years) and 9 old (67 ± 1 years) men had their quadriceps muscle immobilised for 14 days by casting from hip to ankle of one of their legs chosen by random. Muscle biopsies were obtained from vastus lateralis before and after the immobilisation period and muscle specimens were prepared for TEM contrasting in favour of glycogen as described by Marchand et al. (2002). From each of the young and old men 5 were randomly selected for the TEM analysis, which was carried out on images of x40 000 magnifications photographed on systematically randomised locations. All fibres were fibre typed based on mitochondria volume and z-line width. Values are presented as means ± SEM.

Results: There was a strong interaction of immobilisation and subcellular glycogen population ($p < 0.0001$), post hoc analysis showed that immobilisation induced a decrement of intramyofibrillar glycogen by 44 ± 5 % ($p < 0.001$), which was independent of fibre type and age group. In contrast, immobilisation did not change the glycogen content localised in the intermyofibrillar or subsarcolemmal spaces. Thus, immobilisation lowered the intra- to intermyofibrillar glycogen ratio from 0.15 ± 0.01 to 0.07 ± 0.005.

Discussion: This study showed a novel regulation of subcellular glycogen content in human skeletal muscle: a halving in one population and no change in two other populations due to 14 days of immobilisation. This can be interpreted as follows. Firstly, a translocation mechanism of glycogen from the relatively minor store in the intramyofibrillar space to the major intermyofibrillar store exists and is active during immobilisation. Secondly, during the 14 days of immobilisation a degradation of intramyofibrillar glycogen is incompletely replenished suggesting suboptimal glucose uptake signalling.

ELECTROMYOGRAPHIC ACTIVITY DURING WHOLE BODY VIBRATION: MOTION ARTIFACTS OR STRETCH REFLEX RESPONSES?

KRAMER, A., RITZMANN, R., GRUBER, M., GOLLHOFER, A., TAUBE, W.

ALBERT-LUDWIGS-UNIVERSITÄT FREIBURG, UNIVERSITÄT POTSDAM

Introduction: The validity of electromyographic (EMG) data recorded during whole body vibration (WBV) is discussed controversially. Some authors have suggested filtering because of vibration-induced motion artifacts (Abercromby et al., 2007; Fratini et al., 2008) while others have interpreted the EMG signals as muscular activity caused at least partly by stretch reflexes (Mesters et al., 2002; Rittweger et al., 2003; Kvorning et al., 2006). The aim of this study was to investigate the origin of the EMG signal during WBV using several independent approaches.

Methods: The EMG activity of four leg muscles was determined in ten healthy subjects during WBV. Additionally, to test whether the movement of the cables and electrodes during WBV caused motion artifacts in the EMG signal, special dummy electrodes were developed, thus providing a signal only influenced by motion artifacts, without interference from muscle signals. The three following protocols had the same goal, but used a physiological approach and in addition they were designed to verify whether the characteristics of the EMG signal were consistent with the characteristics of a stretch reflex response. For that purpose, frequency spectra and latencies of mechanically evoked stretch reflexes and of the EMG signal during WBV were evaluated and compared. Moreover, pressure application via a blood pressure cuff served to reduce the amplitude of the short latency component of the stretch reflex, thus allowing an estimation of the stretch reflex contribution to the EMG signal.

Results: The dummy electrodes, designed to monitor motion artifacts, showed almost no activity during WBV. The frequency analyses showed no evidence of motion artifacts. The latencies of the stretch reflex responses evoked by the dorsiflexions in an ankle ergometer were almost identical to the supposed stretch reflex responses during vibration (differences of less than one millisecond). Pressure application significantly reduced the amplitude of both the supposed stretch reflexes during vibration (by 61±17 %, $p<0.001$) and the stretch reflexes in the ankle ergometer (by 56±13 %, $p<0.01$).

Discussion: The present results support the hypothesis of WBV-induced stretch reflexes. Contribution of motion artifacts to the overall EMG activity seems – at least with accurate recording conditions – insignificant. Therefore, we recommend not to filter the EMG signal on account of motion artifacts, due to probable distortion of the information content.

CHANGES IN SINGLE MUSCLE FIBRE SPECIFIC FORCE, MAXIMAL ISOMETRIC QUADRICEPS STRENGTH AND MUSCLE SIZE AFTER 2 WEEKS OF IMMOBILIZATION IN YOUNG AND OLD MEN

HVID, L., ØRTENBLAD, N., AAGAARD, P., KJÆR, M., SUETTA, C.

INSTITUTE OF SPORTS SCIENCE AND CLINICAL BIOMECHANICS, UNIVERSITY OF SOUTHERN DENMARK, DENMARK

Introduction: Immobilization reduces whole muscle strength, which, apart from changes in the neural and tendinous systems, is mainly caused by changes in the muscular system. This becomes apparent both at, the whole muscle and single muscle fibre level, respectively [1]. However, it is unknown whether immobilization-induced changes at the whole muscle and single fibre level, differs between young and old individuals. In a health perspective, such knowledge is important for designing strategies to counteract the deleterious effects of immobilization, especially in elderly which are frequently exposed to periods of disuse (e.g. due to hospitalization and disease) [2]. Our purpose was to evaluate the effects of lower limb immobilization on whole muscle strength and size, as well as on single muscle fibre specific force in young and old men.

Methods: 11 young (Y: 23.6±0.5 yrs) and 9 old (O: 66.7±1.3 yrs) healthy men with similar activity level underwent 2 wks of randomized unilateral whole-leg casting, with tests prior to and after immobilization. Measurements at the whole muscle level included max isometric knee extensor torque (MVC) and quadriceps anatomical cross-sectional area (QCSA) at the mid femur [3]. Measurements at the single

muscle fibre level (290 fibres in total, biopsies obtained from vastus lateralis) included cross-sectional area (CSA) and max Ca2+-activated force (P0) used to estimate single muscle fibre specific force (SF = P0/CSA) [4]. Subsequently single fibre MHC analysis was performed.

Results: Prior to immobilization: O had lower MVC, QCSA, and MHC IIA SF compared to Y (41.8%, 10.2%, and 15.9%, respectively; p<0.05). After immobilization: MVC decreased to a similar extent in Y (15.4%: 3.04±0.16 to 2.56±0.14 Nm/kg, p<0.05) and O (15.5%: 1.77±0.14 to 1.50±0.15 Nm/kg, p<0.05), QCSA decreased more (p<0.05) in Y (7.2%: 71.97±2.57 to 66.56±1.76 cm2, p<0.05) than O (4.8%: 64.60±1.69 to 61.46±1.33 cm2, p<0.05), SF for MHC I and IIA fibres decreased similarly in Y (21.5%: 66.6±4.5 to 52.3±4.2 kN/m2 and 27.6%: 120.6±5.7 to 87.4±5.4 kN/m2, respectively, p<0.001) and O (14.7%: 60.4±3.0 to 51.6±3.7 kN/m2 and 33.0%: 101.4±7.8 to 67.9±6.3 kN/m2, respectively, p<0.001).

Conclusion

The present data demonstrate that, 2 wks of lower limb immobilization leads to a similar magnitude of muscle strength decrease (~15%) in young and old individuals. The mechanisms by which this occur seem to be age-dependent, as indicated by a larger decrease in quadriceps cross-sectional area in young compared to old subjects. However, as both MHC type I and IIA single muscle fibre specific force decreased to an almost parallel extent in young and old, other changes within the muscular, tendinous and/or neural systems must have contributed to the observed decrease in whole muscle strength.

LOWER LIMB STRENGTH AND POWER IN RELATION TO MUSCLE CROSS-SECTIONAL AREA IN YOUNG FEMALE BALLET DANCERS AND NON DANCERS

MAIR, J., DEWHURST, S.

UNIVERSITY COLLEGE DUBLIN., UNIVERSITY OF STRATHCLYDE

Female ballet dancers belong to a group of athletes who need to balance aesthetic and performance requirements. In particular, high levels of strength and power are needed to perform effectively, but within the aesthetic constraints of a low body mass and lean physique. To date, however, these seemingly paradoxical requirements have not been examined in ballet dancers. With approval from the University of Strathclyde ethics committee, six female ballet dancers (mean, s) age18.3 years, s = 0.8, body mass 53.5kg, s = 4.7, height 163.8cm, s = 3.6 and seven weight matched physically active female non-dancers age 20.1years, s = 0.9, body mass 55.6kg, s = 6.3, height 163.4cm, s = 6.2, participated in the study. Isokinetic peak torque of the knee extensors at four velocities (60°.s-1, 120°.s-1, 180°.s-1, 360°.s-1) and maximal voluntary isometric contraction (MVC) of the knee extensors and flexors were measured using an isokinetic dynamometer. Surface electromyography (sEMG) signals were obtained during all strength trials from the vastus lateralis (VL) and the biceps femoris (BF) muscles using a 4 electrode linear array. The cross-sectional area (CSA) of the knee extensor muscle group was calculated from ultrasound measurements. Maximal muscle power was estimated from three types of vertical jumps, squat jump (SJ), countermovement jump (CMJ) and a single leg jump, using a force platform. The two tailed unpaired t-test was employed to test for differences between dancers and non-dancers. The criterion for significance was set at p ≤ 0.05. Results show that while both subject groups had similar knee extensor CSA (dancers = 84.5 cm3, s = 6.1, non-dancers = 78.0 cm3, s = 4.9), the dancers produced a 28.7% greater MVC (dancers = 150.4 Nm, s = 23.4, non-dancers = 116.9 Nm, s = 16.2; p≤ 0.01). Similarly, torque values were greater in the dancers compared to non-dancers at all isokinetic velocities, ranging from 19% greater at 60°.s-1 to 4.6% at 360°.s-1 although no results reached significance. Vertical jump data show that dancers produced a greater power output of 27.4% in the SJ (p≤ 0.05) and 15% in the single leg jump (p≤0.05) compared with non-dancers. The root mean square (RMS) and median frequency (MDF) of the sEMG were similar for both groups (RMS: 0.28mV, s = 0.15 and 0.23mV, s = 0.13; MDF: 75.6Hz, s = 4.6 and 71.7Hz, s = 21.6, for dancers and non-dancers respectively), as was antagonist co-activation (dancers = 21.8%, non-dancers = 25.7%). These results suggest that female ballet dancers, in comparison with non dancing controls, are capable of producing high contractile forces from a relatively normal leg muscle mass, thereby maintaining the aesthetic appearance essential for professional level dance. This difference was not however explained by differences in the muscle activation recorded from the sEMG or through differences in antagonistic co-activation.

HIGHER EXERCISE INTENSITY IS LINKED TO CHANGES IN FRONTAL LOBE ACTIVITY

BRÜMMER, V., SCHNEIDER, S., ASKEW, C.D., STRÜDER, H.K.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: The relationship between physical exercise and the human brain is going to develop as one of the key areas of sports medicine and science. To date the display of neural processes within the brain did require extreme complex and costly methods such as PET and fMRI. While both seem therefore only applicable to a small number of approaches, low resolution brain electromagnetic tomography (LORETA) enables the spatial identification and analysis of brain cortical activity via traditional EEG recordings. This study aimed to identify cortical regions that are affected by physical exercise.

Methods: EEG was recorded before and after running at 50% and 80% V02peak on 18 healthy subjects aged 20-45 years. LORETA analysis of alpha-, beta- and gamma-activity served to statistically identify and display cortical regions that were affected by exercise. While alpha activity generally reflects normal brain function, beta indicates excitatory CNS activity.

Results: After 80% exercise intensity data revealed a temporary increase of alpha-activity (8-12Hz) in the frontal lobe combined with a decrease of beta-activity (12-35) and gamma-activity (35-48Hz) in the occipital and temporal lobes immediately post exercise. Fifteen minutes post exercise the alpha increase vanished whereas beta and gamma changes remained stable. No significant changes were found after exercise intensity at 50% V02peak.

Conclusion: A decrease of brain cortical activity, especially in the higher frequency areas has been postulated before and was interpreted as a decrease of cortical excitability. The fact that this now can be localised in specific regions might enhance the discussion about effects of exercise on brain performance and efficiency.

THE POSSIBLE ROLE OF SEROTONINE, DOPAMINE AND NORADRENALINE IN CENTRAL FATIGUE

ROELANDS, B., MEEUSEN, R.

VRIJE UNIVERSITEIT BRUSSEL

Introduction: The central fatigue hypothesis is based on the assumption that during prolonged exercise the synthesis and metabolism of central monoamines, in particular serotonin (5-HT), dopamine (DA) and noradrenaline (NA), are influenced (Meeusen,2006). It is not known however which neurotransmitter system is responsible for accelerating or delaying the onset of fatigue during prolonged exercise. The influence of ambient temperature on fatigue is well studied, but there are little available data on the combined effects of pharmacological manipulations and environmental heat stress on performance. Therefore, the effects of acute administration of individual 5-HT, DA and NA reuptake inhibitors (5-HTRI, DARI, NARI) on performance and thermoregulation were examined in normal and high ambient temperature.

Methods: In three separate studies, between 8 and 11 healthy trained male cyclists completed four experimental trials (two in 18°C, two in 30°C) in a double blind-randomized crossover design. Subjects ingested either a placebo or drug (Citalopram – 5-HTRI, Reboxetine - NARI, Ritalin - DARI) on the morning of the trial. Subjects cycled for 60 min at 55%Wmax, immediately followed by a time trial to measure performance. Tcore, skin temperature, heart rate, blood pressure, sweat loss, RPE, thermal stress, blood lactate and hormonal data were recorded. The significance level was set at $p<.05$.

Results: 5-HTRI did not induce any significant change in performance in 18 and 30°C ($p=0.518$; $p=0.112$; Roelands,2009). DARI improved performance in high ambient temperature with more than 7min ($p=0.049$; Roelands, 2008a). Core temperatures rose significantly higher compared to placebo ($p=0.05$) while no changes in RPE and thermal stress were found. NARI decreased performance by 3min in 18°C and 8min in 30°C ($p=0.018$;$p=0.007$; Roelands,2008b).

Discussion/Conclusion

5HTRI did not cause a change in exercise capacity, thereby confirming other studies (Meeusen,2001; Strachan,2004;2005) and indicating that the role of 5-HT in the onset of fatigue during prolonged exercise is limited in humans. It appears that DA neurotransmission is capable of increasing motivation and drive to continue exercising, even at very high core temperatures, without changing the subjects' perception of effort and internal temperature. Manipulation of NA neurotransmission, in contrast, has negative effects on performance. In conclusion, most probably central fatigue is caused by a complex interplay between the different neurotransmitters systems, with the most important role for the catecholamines DA and NA on either side of the performance spectrum.

OP-PH04 Physiology 4

DIFFERENCES IN INFLAMMATORY PLASMA CYTOKINE RESPONSE FOLLOWING TWO ELITE FEMALE SOCCER GAMES SEPARATED BY 72 H RECOVERY

ANDERSSON, H., BØHN, SK., RAASTAD, T., PAULSEN, G., BLOMHOFF, R., KADI, F.

SCHOOL OF HEALTH AND MEDICAL SCIENCES

Introduction: Because of the combination of high systemic and local muscular stress in soccer games, a substantial inflammatory response may be expected. The inflammation response leads to the secretion of cytokines by inflammatory cells (Ostrowski et al., 1999). A thorough evaluation of the inflammatory response during female soccer games would provide new insights into physiological alterations occurring during games and the recovery following games. Thus, the aim of the study was to investigate changes in a large battery of pro- and anti-inflammatory cytokines in elite female soccer players following two 90-min games separated by 72 h active or passive recovery.

Methods: Blood samples were taken from 13 players (23±4 yrs 167±6 cm, 64±6 kg, 54±3 ml•kg-1•min-1) before, immediately, 21 h, 45 h, 69 h after the first game and immediately after the second game. Leukocyte count was analyzed together with several plasma pro- and anti-inflammatory cytokines using sandwich immunoassay based protein array system.

Results: Immediately after the first and second game, total leukocytes and neutrophils significantly increased. Increases ($P<0.05$) in pro-inflammatory (IL-12, TNF-a, INF-γ, IL-17), chemokines (MCP-1, IL-8 and MIG), anti-inflammatory (IL-2R, IL-4, IL-5, IL-7, IL-10, IL-13, INF-a) and the mixed cytokine IL-6 occurred immediately after the first game. Leukocyte and cytokine levels were normalized within 21 h. Active recovery (low intensity exercises) did not affect the cytokine response. A dampened cytokine response was observed after the second game as only IL-12, IL-6, MCP-1, IL-8 and MIG increased ($P<0.05$).

Conclusion

An elite female soccer game leads to an immediate mobilization of immune cells and a robust, but transient, increase in plasma concentration of both pro- and anti-inflammatory cytokines. Moreover, IL-12, IL-6, IL-8, MCP-1 and MIG seem to be important immunoregulatory cytokines following soccer games and may play important roles in the recovery processes following soccer games. Active recovery training on the days between the games does not seem to affect the cytokine response. Interestingly, when a second game is played 72 h after the first game a dampened cytokine response occurs. Further investigations should aim to understand the mechanisms behind the dampened cytokine response when two games are separated by 72 h. The finding that one elite female soccer game induces a well-orchestrated pro- and anti-inflammatory cytokine response does not support the use of anti-inflammatory drugs before or after one game in well-trained soccer players. However, the dampening of the cytokine response observed after a second game played 72 hours after the first one might have negative effects, especially during female soccer tournaments where several games are played within few days.

BRONCHIAL EPITHELIAL DAMAGE INDUCED BY INTENSE EXERCISE IN RUNNERS

CHIMENTI, L., BONSIGNORE, M.R., PATERNÒ, A., SANTAGATA, R., MORICI, G.

UNIVERSITY OF PALERMO

Introduction: We previously reported increased neutrophils (PMN) in induced sputum (IS) of nonasthmatic runners at rest and after a Marathon (M) race (Bonsignore et al, 2001) and training-induced mild epithelial damage in a mice model (Chimenti et al, 2007). To further characterize airway cell composition, IS samples were analyzed in experienced endurance runners at rest (R) and after Half Marathon (HM) races.

Methods

IS samples (NaCl 5%) were collected in 9 runners (mean age±SD: 40±4 yr, training volume: 85±26 km/week) at rest (3 days pre-race) and shortly after HM races

held in October, May and November.

Results: Differently from the results in M runners, PMN were unchanged or decreased after HM, while bronchial epithelial cell (BEC) differential counts increased after all HM races (% BEC: October, 0.9±1.2 at R, 27.7±21.5* after HM; May, 1.7±2.6 at R, 33.3±21.8* after HM; November, 1.5±2.6 at R, 22.6±26.9* after HM; *p<0.05 vs R). BEC apoptosis also occurred after all HM races (% apoptotic BEC:October, 0±0 at R, 25.0±7.5* after HM; May, 0±0 at R, 14.7±8.2* after HM; November, 0±0 at R, 11.8±12.6* after HM;*p<0.05 vs R).

Discussion: These data suggest a complex time course of airway cells during endurance exercise, with BEC counts increasing early during exercise, and PMN influx into the airways predominating during prolonged exercise (i.e Marathon). This interpretation is in line with previous data obtained in a mice model (Chimenti et al, 2007), and suggest that PMN influx may be secondary to mild bronchial epithelial damage caused by intense exercise.

MUSCLE MORPHOLOGY IN HUMAN NECK AND LEG MUSCLES

VIKNE, H., GUNDERSEN, K., MÆHLEN, J., VØLLESTAD, N.

UNIVERSITY OF OSLO

Introduction. It is well established that neck pain can lead to reduced neck function and altered motor control of neck muscles in humans. Even though knowledge of muscle morphology is important to understand muscle function, human neck muscles have been scarcely studied morphologically. In this study we examine a neck flexor muscle (sternocleidomastoideus), a lateral flexor (scalenus medius), an extensor muscle (splenius) and two reference muscles ñ one located in close proximity to the neck muscles (trapezius) and one remotely located (vastus lateralis).This knowledge will help interpreting the functional impact of motor control patterns.

Methods. Muscle autopsies are taken from the sternocleidomastoideus, trapezius, splenius capitis, scalenus medius and the vastus lateralis muscle of so far 8 human subjects 1-3 days post mortem. Subjects were between 18 - 65 years at the time of death. Muscle autopsies are frozen in melting isopentane and serial transverse sectioned in 10µm samples using a cryostat. Fiber type composition and vascularisation are assessed by immunohistochemistry. The fiber type composition is based on the staining patterns of four monoclonal antibodies (BA-D5, SC-71, BF-35 and 6H1) against myosin heavy chain (MyHC)1, MyHC2A and MyHC 2X. Anti-CD-31 (JC70, DAKO) is used for measurement of vascularisation and anti-laminin (Sigma) for visualisation of the basal lamina for measurement of muscle cell cross-sectional areas. MyHC and laminin presence are visualized using immunofluoresence - and CD31 by immunoperoxidase staining. Cell nuclei are stained using haematoxylin.

Analysis. Muscle samples are divided into four quadrants using the laminin staining section and 400 cells in two random quadrants are numbered giving a total of 800 cells blinded for MyHC staining. The fiber identities of these cells are then determined on basis of the four MyHC staining patterns. After inspection of cell integrity the cross sectional area of 80 cells of each fiber type are measured planimetrically using the laminin staining images in the ImageJ software. The microvessel density in muscle samples are assessed by several procedures. First, the number of vessels per area (mm2) and the vessel to fiber ratio in the same area are measured. Also, the number of vessel around single fibers and the number of vessels relative to fiber area are calculated. The data of fiber type composition, fiber cross-sectional area and microvessel density from the different muscles will be compared. Also, separate between- subject analysis will be completed.

Results. Preliminary results of the fiber type composition of the vastus lateralis muscle show that subjects have 33 +/- 10 % type 1, 35 +/- 8 % 2A and 13 +/- 8 % 2X fibers. A large number of hybrid 2A/X fibers were found (18 +/- 9 %) while hybrid fibers containg both MyHC 1 and 2A were scarce (0.8 +/- 0.9 %). Complete results will be presented at the ECCS congress.

COMPARISON OF A TASK-RELATED TEST VERSUS NATIONAL LABOUR INSPECTION AUTHORITY ENDURANCE AND STRENGTH TESTS FOR FIREFIGHTERS AND APPLICANTS

HEIMBURG, E., MEDBO, J.I., SANDSUND, M., REINERTSEN, R.E.

NORTH TRONDELAG UNIVERSITY COLLEGE

Introduction: Firefighting is physically very demanding (Heimburg et al., 2006). Consequently, the Norwegian Labour Inspection Authority (NLIA) has set minimum requirements to firefighters' physical ability by approving laboratory endurance and strength tests. Other tests with similar physical requirements, f. ex. task-related tests (TR), may be used as substitute. This study therefore compares performance on a TR-test, proposed to be an alternative, with the NLIA-tests.

Methods: Firefighters (24 seniors, 19 young) and 20 young applicants (12 males, 8 females) were dressed up for smoke diving (wearing 23 kg), carried out all tests while scores were recorded.

The TR-test includes following tasks: carrying four cans of 23 kg each 11 m, crawling thru a 2 m long and 60 cm wide tunnel, balancing on a 4 m long and 10 cm wide beam, connecting and disconnecting ten firefighting hoses, twice pulling a fire-hose weighing 32 kg a distance of 58 m including stair climbing, physical work in a heat chamber (>120 °C; moving 20 concrete blocks of 18 kg each alternately up and down a stair). Performance is time to conclusion.

The NLIA endurance test of 8 min of standardised treadmill walking was modified by extending exercise by stepwise increases in intensity to volitional exhaustion, obtaining time to exhaustion and peak VO2 as continuous outcome variables. NLIA strength tests based on number of repetitions were squat-and-raise, push-ups, and horizontal pull-chest-to-bar-test.

Results: VO2 rose linearly by duration of the extended NLIA treadmill-test. Young men walked longer than senior firefighters and female applicants did. Time spent on the TR-test was closely related to performance on the extended NLIA-test, suggesting that VO2-max is important for the performance. A firefighter completing the TR-test in less than 21 min meets requirements of the NLIA treadmill-test. Performance on the TR-test was not closely related to muscle strength beyond a minimum. Male firefighters and applicants performed as well on the TR-test as on the NLIA-tests, but females performed relatively poorer on the TR-test.

Discussion: The close relationship between performance on the TR-test and the NLIA treadmill-test suggests that the TR-test distinguishes well between physically fit and less fit firefighters and applicants; it may thus be a substitute for the NLIA treadmill-test. The relative poorer performance of females on the TR-test may be caused by their lower body mass and muscular strength that may be a disadvantage for performing firefighting-like activities but not for laboratory tests. As long as the NLIA-approved test is the norm, the TR-test may discriminate against females. The TR-test does not seem to challenge muscle strength.

PHYSICAL FITNESS AND PHYSICAL ACTIVITY IN NORWEGIAN HOME GUARD SOLDIERS

AANDSTAD, A., HAGEBERG, R.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Soldiers' physical fitness is considered to be an important factor in military operations. A desired level of fitness can be developed from sufficient exercise training. Regular Home Guard soldiers (HGS) only undergo military repetition training for about 3-5 days a year. Since HGS primarily live a civilian life, no obligatory military physical training is completed, and the fitness level is not monitored, as opposed to i.e. professional soldiers and recruits. Hence, the aim of this study was to measure fitness and activity level in regular HGS, and identify whether these soldiers were sufficiently fit for military work.

A total of 710 male HGS (age 32.8 ± 4.6 yrs) from five districts have participated in the study. Physical measures were conducted during regular military repetition service, while physical activity has been measured during and after the repetition service. The 20 m Shuttle Run Test (Leger et al., 1988) was conducted to estimate maximal oxygen uptake (VO2max). Percent body fat was estimated from bioimpedance measurements (Quantum II, RJL Systems, USA). Other anthropometric measures were height, weight and waist circumference. Physical activity was measured for 9 consecutive days with SenseWear Pro2 Armband (Bodymedia, USA).

Estimated VO2max was 49.0 ± 6.5 ml/(kg∙min) in the Norwegian HGS. Mean height and weight were 180.1 ± 6.7 cm and 85.0 ± 13.3 kg, and mean BMI was 26.2 ± 3.7. Thirteen percent of the soldiers were obese (BMI ≥ 30). Mean waist circumference were 94.5 ± 10.1 cm, and 20 % of the soldiers had an waist circumference of ≥ 102 cm. Mean percent body fat was 19,4 ± 5,8. Physical activity estimated with the Armband monitor during regular weekdays showed a mean energy consumption of 3479 ± 787 kcal/day. The HGS walked 10.202 ± 4336 steps/day, and had a mean METS value of 1.77 ± 0.40. Physical activity level during weekends was slightly lower than during weekdays, while the activity level during repetition service was generally similar to regular weekdays.

Norwegian HGS had lower aerobic fitness compared to Norwegian male cadets, recruits and soldiers in Special Forces. This finding was expected since i.e. the HGS are somewhat older than other groups of Norwegian soldiers, and the fact that no fitness demands exist for regular HGS. However, for military personnel, police, firefighters etc a minimum acceptable aerobic fitness level has been claimed to be 43 ml/(kg∙min) (Shephard, 1991). If this criterion is taken into account, 80 % of the HGS met the minimum acceptable level. About 13 % of the HGS were overweight in terms of BMI, while 20 % had a high waist circumference. Hence, several HGS had an increased risk of i.e. cardio-vascular diseases. Most HGS met the recommendation of a minimum of 30 minutes/day of moderate intensity physical activity. However, more physical activity with high intensity could be recommended.

"VO2 SLOW COMPONENT" ABOLISHED AFTER WARM UP WITH APNEAS

SCHAGATAY, E., BJÖRKLUND, G.,3, RYDH, F.

1. DEPT OF ENGINEERING AND SUSTAINABLE DEVELOPMENT, 2. SWEDISH WINTER SPORTS RESEARCH CENTRE, 3. DEPT OF HEALTH SCIENCES

Introduction: The cause of the "VO2 slow component" (SC), i.e. a slow further rise in VO2 during continued intense exercise after the fast rise during the initial 2-3 min, has not been settled, but suggested candidates are alterations in fibre recruitment, muscle acidosis, and muscle temperature. Spleen contraction during exercise (Laub et al.,1993) or apnea (Schagatay et al., 2001) is known to inject a stored supply of red blood cells into circulation. Our aim was to study if the SC could be related to an increase in hemogloin concentration (Hb) caused by spleen contraction, a factor never studied in this context before. The elevated Hb could facilitate oxygen delivery to the active muscles and increase buffering.

Methods

Eight male cyclists with mean (SD) age 26(4) years, height 183 (7) cm and weight 76(9) kg performed two identical protocols separated by two days, consisting of 3 high intensive periods on a cycle ergometer at 90% for 3 min, spaced by 6 min periods of 70% of VO2max. Series were preceded by 10 min warmup at 50% of VO2max. After warmup one series contained 3 maximal effort apneas preceeded by 1 min of hyperventilation to maximize duration. In the test without apneas, subjects rested sitting after warm-up. Respiratory parameters (AMIS 2001) and heart rate (Polar S610) were recorded continuously. Spleen diameter (ultrasonic imaging), venous Hb (Hemocue) and Lactate (Biosen 5140) were measured before and after warmup, after apneas or rest, and after the exercise.

Results: Mean (SD) duration increased across apnea 1 - 3 from 109(17) s to 142(17) s ($P<0.01$). This increase is typical of repeated apneas and considered to reflect spleen contraction (Schagatay et al 2001). After the protocol with apneas the spleen volume was smaller and venous Hb higher than after rest without apneas (both $p<0.05$). At this point before exercise lactate was also higher after apneas (1.42 versus 0.96 mmol *L-1; $P<0.01$). In the series without apneas, VO2 increased by 50 ml/min between the high intensity period 1 and 2 ($P<0.05$), and by 60 ml/min between period 1 and 3 ($P< 0.01$), but no change was observed in the exercise test preceded by apneas.

Conclusions

We concluded that in the maximal work test preceded by apneas, the spleen contraction and resulting Hb elevation abolished the slow component. Thus VO2 max will not be reached before the blood-boosting spleen contraction is induced, which takes several minutes during work alone, but is pre-triggered when work is preceded by apneas. Also lactate or other effects of apnea and/or hyperventilation may affect the peak VO2, which calls for further study.

IS-BM05 Complex systems in sport

COMPLEX SYSTEMS AND PHYSIOLOGICAL TESTING

VAINORAS, A., BALAGUE, N.

KAUNAS UNIVERSITY OF MEDICINE, LITHUANIA; INEFC , BARCELONA, SPAIN.

Introduction: The complex systems approach to physiological testing in sport science is offering a chance to cope with the holistic nature of the organism, giving information about the synergies of the main systems interacting during the exercise and their fractal characteristics (Goldberger, 1997). The aim of this study is to introduce the basis of the complex approach to physiological testing and summarize the main results obtained by the application of the Kaunas Load system in the evaluation of overtraining and exercise induced fatigue and failure.

Methods: A formalized model and its software, involving the main holistic systems -muscles and bones (periphery system), cardiovascular (supplying system), and regulatory system, has been used for the evaluation of trained individuals (Vainoras, 1997). A system of parameters has been elaborated to reveal the behaviour and dynamics of the organism during the application of cycle ergometer workloads and during the recovery period. The parameters are based on the synchronous registration of standard 12 lead ECG, arterial blood pleasure and developed power. In the model some new and a set of nonlinear parameters –evaluation of sample entropy and evaluations with the help of Hankel matrix are determined. The sensitivity to the model and its parameters to special features as overtraining, fatigue and failure induced by exercise have been checked and will be discussed.

Results: The system and some evaluated parameters (Ad) have shown its sensitivity to special features as overtraining effects on the organism. The evaluation of sample entropy and Hankel matrix analysis, as measures of organism complexity, revealed its sensitivity in the study of the fatigue and failure during cycle ergometer endurance exercise. Both indicators decrease with the development of load, returning to their initial values during the recovery period. A special hallmark is the increase in complexity observed before the failure point is reached.

Discussion: The model and its software have been proven as being useful in the investigation of the human organism complexity during exercise and have shown its sensitivity to some syndromes of complex nature as overtraining and fatigue and failure induced by exercise. The computerized system is used for research purposes and is being applied to Lithuanian sportsman -from early ages up to the Olympic team members. The main advantages of the system are related with the fast diagnostic and early detection of abnormal reactions to workload exposures that are not possible through the more classical physiological testing Methods: References

MANIPULATION OF TASK CONSTRAINTS AND REPLICA SYMMETRY BREAKING. AN ANALYSIS OF NOVEL PATTERN FORMATION

HRISTOVSKI, R.

UNIVERSITY SS ¨CYRIL AND METHODIUS¨

Introduction: According to Sternberg & Lubart (1999) creativity is defined as an activity of generating novel and appropriate (i.e. satisfying goal constraints) products. Within the constraints –led framework on action formation a generative system can be defined as a set of task, personal and environmental constraints coupled to the action degrees of freedom of the performer. Using the tools of glassy state physics which is a paradigm of complexity it may be shown how it can be used for capturing the most prominent features of creative behavior in sport movements, that is, the generation of novel appropriate patterns.

Methods: An experiment of hitting actions was conducted. 6 participants unfamiliar with the task of hitting were asked to strike a frontally positioned heavy bag from various positions and under varying energy of hand-target impact demands. The hand trajectories of performers were analyzed by calculating the static and dynamic overlaps of the upper limb configurations and the probability distribution function of the overlaps as well as by constructing a hierarchy of movement configuration states. In line with the glassy physics the hierarchical states were interpreted as order parameters.

Results: Manipulation of task constraints brought about emergence of novel and appropriate behaviors of performers. Initially rare, nucleating movement variations grew, stabilized and dissolute as the task constraints were varied. The probability distribution function of the overlaps showed effects of replica symmetry breaking by showing peaks other than that of a zero overlap values. The hierarchical structure also changed as a function of the task constraints. The dynamic overlaps showed an ergodicity breaking behavior and divergence of the relaxation time. The relative entropy exhibited non-analytic behavior at the points of emergence of novel configurations.

Discussion: The investigation showed how the manipulation of task constraints leads to formation of novel and appropriate movement configurations which is a hallmark of creative behavior. The results generalized the previous findings (Hristovski, Davids & Araújo, 2006). By making task constraints more released or stringent movement configurations evolved from boxing to karate and dance-like patterns. The glassy state modeling seems an appropriate mathematical model of a generative system of sport movements.

A COMPLEX SYSTEMS APPROACH TO THE STUDY OF SPORT GAMES

ARAUJO, D.

TECHNICAL UNIVERSITY OF LISBON

This talk will address ball games in sport based on the evidence that in such complex systems multiple causes produce multiple effects. Following this perspective, for the study of a match, more than analysing it by decomposing the game in multiple variables, it may be beneficial the search for a synthesis of it, by identifying the collective variables that describe and explain the game, in a way simpler than the game itself. Therefore, the search for patterns, as well as transitions among them, the identification of attractors and repellors that change over time, as well as the identification of patterns of collective interactions, may suit this endeavour. We will illustrate these ideas using studies conducted in team ball sports such as rugby and football, showing the same dynamical proprieties both at an individual and at a collective level.

OP-PS03 Psychology 3

THE EFFECT OF THE COACHES' PROFESSIONAL EXPERIENCE ON ATTITUDES AND ACHIEVEMNT GOALS IN YOUTH SPORT

GONÇALVES, C., SANTOS, A., COELHO E SILVA, M.

UNIVERSITY OF COIMBRA

Coaches are believed to have an important role in shaping the quality of the youhg athletes experiences. Scholars suggest that the climate fostered by the coach can influence the athletes' achievement orientations and moral attitudes. The purpose of this study is to examine the effects of the soccer youth coaches' professional experience on (a) the style of communication in competition, analysed through the Coach Behaviour Assessment System (CBAS); (b) the sport attitudes (Sports Attitudes Questionnaire/SAQ), and achievement goals (Task and Ego Orientations in Sport Questionnaire/TEOSQ), (c) the perceptions of coaches' behaviour (CBAS perception questionnaire), as expressed by the athletes.

Methods: Six soccer coaches were observed. Three of the coaches were experient, the other three were in their first coaching season. Eighteen games were vídeo recorded, three for each coach. The recordings were analysed and registered in the CBAS sheet. The athletes of the observed teams (n=106, 55 playing for an experient coach and 51 playing for an unexperient one; mean age 14,8 years, SD±0.95), fullfilled the portuguese versions of SAQ, TEOSQ and CBAS. To analyze the effects of professional experience

on dependent variables t-test and ANOVA were performed.

Results and Discussion: All the observed coaches stressed positive reinforcement, technical instruction, and general communication, although with major individual differences which don't discriminate the coaches by level of professional experience. In TEOSQ no effect from professional experience on dimensions task and ego was found. In SAQ significant effects were found on convention and commitment, the athletes from experient coaches showing higher scores, but no effects were found on cheating and gamesmanship. In CBAS the athletes from experient coaches'teams perceive better tactical instructions but less afective support and encouragement than their peers playing for unexperient coaches.

Conclusions: The level of professional experience of the coach seems to have no effect on the type of communication in competition, on achievement goals, and on negative sport attitudes. These effects are identified on positive sport attitudes and in the CBAS itens related to support, reinforcement and tactical instruction. The lack of a pattern of results discriminating experient from unexperient soccer coaches suggests that future programs to foster sportpersonship among coaches must be individualized.

STABILITY OF GOAL ORIENTATIONS IN DUTCH TALENTED ADOLESCENT FIELD HOCKEY PLAYERS

ELFERINK-GEMSER, M.T., STARKES, J., MEDIC, N., VISSCHER, C.

UNIVERSITY OF GRONINGEN, UMCG; MCMASTER UNIVERSITY, CANADA; THE UNIVERSITY OF WESTERN AUSTRALIA, AUSTRALIA

Introduction: The adolescent period is characterized by extreme changes in virtually every aspect of an athlete's performance. To ultimately meet international performance standards later on, athletes have to develop their physical, physiological, and technical performance characteristics fairly quickly (Elferink-Gemser et al., 2006; 2007). However, is this also the case for psychological variables such as motivation? With the importance of goal orientations in understanding achievement motivation in sport and exercise being widely recognized by researchers (e.g., Duda, 1992), the purpose of this study was to examine how stable task and ego orientation are for talented adolescent athletes.

Methods

Participants were 41 (20 male and 21 female; mean age 14.0, sd 1.1 at the first measurement) talented field hockey players who filled in the Task and Ego Orientation in Sport Questionnaire (TEOSQ; Duda and Nicholls, 1992) four times over a 4-year period.

Results: Intra-class coefficients, the percentage of participants with differences that were within ±1 range of the mean test scores (proportion of agreement test), repeated measures MANOVA, and paired sample t-test scores showed that players' goal orientations changed marginally from year-to-year and across a period of 4 years ($p>.05$).

Discussion: In order to persevere in a highly competitive environment, talented athletes require high levels of both task and ego orientation (Van Yperen and Duda, 1999). The results in the present study confirm relatively high scores on task as well as ego orientation for both male and female talented field hockey players, with task orientation scores comparable to other studies and ego orientation scores higher (Duda and Whitehead, 1998). The results also show that motivational orientations appear to be highly stable over a 4-year period and independent of one's relative skill or physical maturity. An implication of these findings is that one measure of an athlete's goal orientations during adolescence appears to be sufficient. Whether these results are specific for Dutch field hockey players or whether they can be generalized to other populations of adolescent talented athletes has to be investigated. The results are unique because this is one of the first studies to apply a longitudinal design examining the stability of talented adolescent athletes' goal orientations over a period of four years.

MOTIVATION AND GOALKEEPING: COPING WITH MEDIA REPORTING OF SAVES AND FAILURES

KRISTIANSEN, E., ROBERTS, G.C.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: As a part of a larger study investigating media reporting as a stressor for elite athletes, this study investigated the experience of professional football goalkeepers when coping with media reports on their performance. The sport media typically presents sporting images by exaggerating the spectacular, inventing and focusing on rivalries, and manufacturing reasons why we should pay attention to different sports events. The media tells the story the way those who benefit from cultural commitments to competition, productivity, and material success. One popular theme is the success theme, but lurking behind every success story is someone else's failure. Within the football environment, goalkeeping failures often become the media reason why one team wins and another loses. The media does not cover learning, progress, or enjoyment (mastery motivation), rather they cover winning, great individual performance, and success and failure. In motivational terms, the media is attracted to ego involving criteria, where players are compared and lionised if successful, or demonised if they fail. From research, we know that to keep people motivated and performing optimally, we need to be mastery involved and concentrate on one's own performance and successes (e.g., Roberts, 2001). However, the media only looks ego involving criteria of what is success and failure. How do the goalkeepers relate to these conflicting views of what is success and failure in their role as an elite athlete?

Methods: We used qualitative, in-depth, semi-structured interviews conducted in 2008. Participants were 3 goalkeepers in the Norwegian elite division. The goalkeepers were all asked about the goalkeeper's importance on the team and the framing of goalkeepers in the news media. The interviews were transcribed verbatim and coded with main categories and associated sub-categories before analysis.

Results and Discussion: The goalkeepers considered the news media to overestimate the importance football players should place on the game, and disagreed with the framing of matches in the media. As a result, they used many different coping strategies to cope with what they considered to be the interfering media attention. Avoidance of the media representatives and of reading what was written was a coping strategy frequently mentioned. All three goalkeepers claimed that they did not have the faintest idea what the media wrote about them. In addition, they had also instructed family and friends not to tell them, especially before games. Instead, they tried to focus on their tasks in the game and rely on their own/or the coach's evaluation of it later (mastery motivation involvement with vigilance coping). The goalkeepers understood why the media was interested in them, but they disagreed with the framing of their performances in order to sell newspapers.

GOAL ORIENTATION, MOTIVATIONAL CLIMATE, BASIC PSYCHOLOGICAL NEEDS AND PERCEIVED COMPETENCE AMONG YOUNG ELITE CROSS-COUNTRY SKIERS: A LONGITUDINAL STUDY

NILSEN, D.A., LEMYRE, N., HEGGEBØ, F., PENSGAARD, A.M.

NORWEGIAN SCHOOL OF SPORT SCIENCES

In recent years, a major framework for understanding motivation in sport and physical activity contexts stems from achievement goal theory (Nicholls, 1989) and self- determination theory (Deci & Ryan, 1985). This research has found a relationship between motivational climate and goal orientation and basic psychological needs and self- determined motivation. This research has also confirmed the relationship between perceived self referenced competence and task orientation and self- determined motivation. Even though it has been a widely support for these relationships is it more unclear how perceived normative competence will influence both ego orientation and self- determined motivation in a sport context. Since the major part of the research has included samples where different kind of groups has been measured (e.g. team sports), and very few demonstrates the changes over time with a longitudinal design, is it also unclear how motivation variables will change over time for competitors in individual sports.

The aim of this study was to examine the relationship between perceived motivational climate, achievement goal orientations, basic psychological needs and perceived competence in a longitudinal study. The participants were 38 young elite cross-country skiers between 17 and 23 years old. Inclusion criteria were that all had to compete at a high level, and they had to represent the same sport, cross-country skiing. The participants were asked to respond on a two-part questionnaire. The first part requested demographic information including gender, age, sport specific age, perceived sport level and totally numbers of training hours present season. The second part were formed to measure motivational variables such as goal orientation (POSQ), motivational climate (PMCSQ), situational motivation (SIMS), basic psychological needs (BPNES) and perceived competence (PCS). Data were collected five times; pre- season, three times

during the competitive season, and after the main goal for the season (e.g. the World Championship). Preliminary analyses revealed that there were fluctuations in motivation during the season while perception of competence remained relatively stable. Results and conclusion will be discussed and suggestions regarding motivational issues will be presented.

ARE ATHLETES BURNING OUT WITH PASSION?

GUSTAFSSON, H., HASSMÉN, P., HASSMÉN, N.

KARLSTAD UNIVERSITY & SWEDISH WINTER SPORT RESEARCH CENTER, MID SWEDEN UNIVERSITY

Introduction: Feeling passionate about sport may help athletes cope with the demands of excessive training needed for a number of years to become successful at the elite level. Passion is thereby seen as a strong motivational force towards an attractive activity, possibly to the extent that it becomes an integral part of the athlete's identity (Vallerand et al., 2003). The concept of passion has been divided into two forms: harmonious and obsessive. Although feeling passionate about sport seems important from a motivational perspective, it may increase the risk for burnout, which is a negative consequence blamed partly on too much training and inadequate recovery (Gustafsson et al., 2008). The question voiced in this study is whether the risk for burnout is equally between harmoniously and obsessively passionate athletes.

Methods: Participants were 94 female and 164 male competitive athletes from 21 sports. Passion was measured with the Passion scale (Vallerand et al. 2003) and burnout with the Athlete Burnout Questionnaire (Raedeke & Smith, 2001). A one-way MANOVA was performed to investigate potential differences between athletes categorized according to type of passion (i.e., Harmonious vs. Obsessive) in the level of burnout.

Results: A significant main multivariate effect was found: $F(7, 250) = 4.85$, $p < .0001$. Follow-up analyses, using a Bonferroni adjusted alpha level of .007, showed significantly higher burnout scores in the Obsessive passion group than in the Harmonious group: Emotional/physical exhaustion, $F(1, 256) = 9.90$, $p = .002$; Reduced sense of accomplishment, $F(1, 256) = 18.39$, $p < .001$; and Devaluation of sport participation, $F(1, 256) = 14.12$, $p < .001$.

Discussion: These findings strengthen the assumption that even though passion may indeed be a vital part of elite sport; athletes scoring high on obsessive passion may be at greater risk for developing burnout than more harmoniously passionate athletes. One possible explanation is that obsessive passion induces a more rigid form of persistence (Vallerand et al., 2003). Interpreted positively, persistence may increase the athletes' chance of reaching their full potential during the competitive season, but rigid persistence can increase the risk for negative outcomes such as the overtraining syndrome and burnout.

CAN TEENAGE FEMALE ATHLETES LIGHT UP IN A HIGH COMPETITIVE SPORT CONTEXT WITHOUT BURNING OUT?

GUILLET, E., GAUTHEUR, S.

UNIVERSITÉ CLAUDE BERNARD LYON 1

Introduction: Female athletes have reported higher levels of competitive state anxiety and train anxiety (Mellalieu, Hanton & Fletcher, 2006) and it has been suggested that they are more susceptible to burnout than their male counterparts (Abrahamson, 1997). Gender differences seem an important psychological parameter as they are likely to influence the quality of the sport experience of high level athletes. The purpose of the current study was to examine whether differences in the anxiety and self-confidence of female and male athletes influence the quality of their sport experience. Based on previous research findings it was hypothesized that female athletes would report higher anxiety and lower self-confidence than male athletes and consequently would also experience lower vitality and higher burnout symptoms.

Method: A sample of 790 French handball players (418 males and 372 females) participated in this study. They trained an average of 11.29 hours a week (SD = 3.6). Their average age was 15.82 years (SD = .97). These athletes completed a questionnaire in April 2007 (T1), November 2007 (T2) and April 2008 (T3), during which we measured: (a) anxiety and self-confidence (EEAC; Cury, Sarrazin, Pérès & Famose, 1999), (b) subjective vitality (SSV; Ryan & Frederick, 1997), and (c) athlete burnout (ABQ; Raedeke & Smith, 2001).

Results: One-way MANOVAs and post hoc tests Newman Keuls were conducted to examine the differences between boys and girls on (1) anxiety, self-confidence, and vitality; and (2) on the three dimensions of burnout. Findings indicated that (1) females had higher scores of cognitive anxiety and lower scores of self confidence and vitality at T1 (Wilks' λ = .90, $F(4, 451) = 11.71$, $p < .001$), at T2 (Wilks' λ = .87, $F(4, 460) = 17.41$, $p < .001$) and at T3 (Wilks' λ = .85, $F(4, 361) = 15.01$, $p < .001$). Females also had higher scores of somatic anxiety at T1 (Wilks' λ = .90, $F(4, 451) = 11.71$, $p < .001$). (2) Males had higher scores of exhaustion at T1 (Wilks' λ = .98, $F(3, 451) = 3.71$, $p < .05$). Females had higher scores of reduced accomplishment at T2 (Wilks' λ = .96, $F(3, 460) = 6.76$, $p < .001$) and at T3 (Wilks' λ = .94, $F(3, 361) = 7.27$, $p < .001$).

Discussion: Based on the current findings, young elite female handball players felt more anxious and reported lower accomplishment, while males were more self-confident. However, male athletes reported higher physical and emotional exhaustion in April 2007. Current findings can't allow us to affirm that females experience higher levels of burnout in a high competitive context. Further investigations are needed.

DROPOUT RATE AND DROPOUT REASONS IN TALENTED TRACK AND FIELD ATHLETES, A 25 YEAR STUDY

ENOKSEN, E., SHALFAWI, S.

1. NORWEGIAN SCHOOL OF SPORT SCIENCES, 2. BODØ UNIVERSITY COLLEGE

Introduction: Research explains the early dropout of young talents in sport as a combination of different inner and outer conditions such as individual talent and personal development, athletic progress, motivation, priorities of interest and influence from the social environment (Ames, 1992; Molinero et al., 2006). The aim of the present study was to identify the total dropout rate and dropout reasons in a group of talented track and field athletes from 1975 - 2000. Methods: 202 males and 98 females aged 16 ±2 years took part in this study. The questionnaires designed in 1975 were sent together with informed consent and local ethics committee approval in September 1975 to 320 participants. The questionnaires designed for the 1983 study and the 1989 study were administered in November 1983, and October 1989. All questionnaires were administrated in written form. The participants who did not respond to the first request were sent a new questionnaire two months after, and those who did not answer the second questionnaire were sent a new and last questionnaire after two months from the second questionnaire. Those who did not answer after the third trial were considered as dropped out. In 1989, 10 athletes were chosen for interviews. In 2000, 24 athletes who had continued their athletic career after 1989 were interviewed. The interviews were conducted in the period between September 1989 and October 1989 for the 1989 study, and from February 2000 to November 2000 for the 2000 study. The interviews varied in time from 60 - 120 minutes. Combining the analysis of the quantitative data and qualitative data was to bring forward more refined and valid information about the variables involved in the processes of dropping out from competitive sport at an early age. A chi-square test was administrated to test the difference between males and females dropping out and to test the most significant reasons influencing the athletes' decision to drop out from competing in track and field. Results: The dropout rate was highest when the athletes were 17 years old. Females were clearly dropping out more than males ($p < 0.05$). Injuries, school demands, and lack of motivation were highly notable reasons to why relatively many athletes dropped out at an early age. Various dropout reasons were important over the life of the study, and differed at the different stages. Conclusion: Today elite sport requires increasingly harder training, tough competitions and constant expectancies of good results. Young talented athletes who fail to meet these requirements may chose to drop out of competitive sport at an early age.

WHAT PEDAGOGICAL/DIDACTICAL COMPETENCE DO SPORTS COACHES HAVE?

HÖGBERG, J.

HEALTH AND SOCIETY

Introduction: It is said that "good leaders are not made, they are born." Attempts to study the truth of this in sports have been made in different studies by e.g. Jones et al (1). In one study they adopted a life-story approach to the coaches´ construction of their knowledge.

The aim of this study is to examine the pedagogical/didactic competence of sports coaches in the planning, execution and evaluation of their training.

Methods: The sample in the study consists of 14 coaches in different sports areas. Their disciples can all be classified as elite, from international to regional level. The coaches´ education levels range from "auto didactical" to academic studies.

The methods used are Stimulated Record (SR) and in-depth interviews. All 14 were observed and interviewed using SR and four coaches were interviewed 1-2 months after the SR study. Lyle (2) claims that "…SR is a valuable tool for investigating cognitive processes, although care has to be taken with research designs."

The didactic competence of the coaches was determined using a three-level model and compared with their experiences in coaching, their experiences as athletes and their education levels.

Results: The results show that there is little correlation between the coaches' experience and didactic skill; that experience as athletes is negative for didactic competence; and that the level of the coached athletes is irrelevant. Four of the coaches reached level three in the model. These four were the only ones to have an academic pedagogical education. This is so far the only positive correlation found between coaching competence and education, coaching experience or skill as an athlete. It seems that tradition, social context and former experiences as athletes have more impact on the coaches´ competence than education within sports.

Discussion: The results will be discussed from an educational point of view. Suggestions to enhance the didactic competence of coaches will be made.

THE NORMALIZATION OF EMOTIONAL ABUSE IN SPORT: AN ECOLOGICAL GROOMING MODEL

STIRLING, A.

UNIVERSITY OF TORONTO

One of the greatest risks to emotional abuse in sport is the inability of the victim to recognize the abuse as problematic (Stirling & Kerr, 2007). The term grooming is used to refer to the normalizing or legitimizing of actions or conditions with the victim and/or within the

broader social community, that enable the offender to abuse a victim with minimal resistance and/or repercussion (van Dam, 2001). Relative to abuse prevention, an understanding of the various grooming factors is particularly important because these factors can bring about the appearance of co-operation from the victim, making acts of abuse seem to be consensual (Fasting & Brackenridge, 2005). To-date, different types of grooming have been examined relative to the coercion of individuals to sexual abuse or sexual molestation (Leberg, 1997). Exploration of the grooming of other maltreatments remains to be examined. The purpose of this study, therefore, was to determine what factors contribute to the grooming of athletes to emotional abuse. Data for the present study were gleaned from a series of previous interviews on athletes' experiences of emotional abuse. Interview transcriptions were included in the present study if the athlete had reported experiences of emotional abuse in the coach-athlete relationship, expressed some degree of present or past acquiescence to his/her emotionally abusive experiences, and was able to articulate various sources of influence perceived to affect his/her acquiescence. As such, data used in the present study included the interviews of 30 elite athletes (male, n= 8; female, n=22) between the ages from 18-25 years. All athletes competed at the national/international level, and a variety of sports were represented. Collective analysis of the data was conducted using open, axial, and selective coding techniques. Interview data were interpreted to suggest that athletes are embedded in and affected by a social context that is comprised of a range of micro to macro spheres of influence. Athletes reflected on influences that were perceived to affect the normalization of their emotionally abusive experiences, including intra-relational, inter-relational, community, organisational, and cultural grooming factors. Based on the study findings an ecological grooming model is proposed. Comparisons are made with the sexual abuse literature, and recommendations are posed for prevention and future research.

THE CONSTRUCTION AND EFFECTIVENESS OF OFFENSIVE PLAYS IN BASKETBALL BY USING SYSTEMATIC OBSERVATION

FERNÁNDEZ, J., CAMERINO, O., ANGUERA, M.T., GIBERT, A., JONSSON, G.K.

INEFC, LLLEIDA.

Introduction: In the field of sports research there is a growing need for the rigorous collection of data that provide empirical evidence about the complex reality they refer to. Key aspects in this regard include the presence of regularities that are not detectable through visual inference or traditional methods of data analysis, the lack of standard observation instruments and the priority need to develop powerful, computerized coding systems, all of which must form part of an approach that is suitable for natural and habitual contexts (Morris & Burwitz, 1989).

Method: The observational methodology used had the rigor and flexibility needed to study the episodes and different configurations of play just as they occurred. Ten ACB basketball games (First Spanish Division) were recorded and the instrument used was the Match Vision Studio software (Perea, Alday & Castellano, 2004), which has enabled us to set up code and category of the situation space of the players in the two previous moves to the basket. The approach here concerns the way in which temporal patterns are able to reveal those aspects of social interaction that are not immediately observable, and considers that every interactive flow is governed by behavioural structures of varying stability that can be visualized by detecting hidden temporal patterns such as T-patterns. These temporal patterns can be detected by means of the powerful algorithm of the THEME software, developed by Magnusson (1996).

Results: A total of 3478 T-patterns were detected in the subset of games won. Given the temporal patterns detected and the results obtained in the lag sequential analysis we then turned our attention to those co-occurrences in which there was a disparity according to game performance.

Discussion: The results show that it is possible to identify stable spatial structures that provide information about areas and positions of players more effective in launching basket and an imbalance that provide more effective for completion and the type of termination of attack that can be applied for the improvement of sports training and initiation. The selection of the data has been grouped into different criteria.

Key words: T- Patterns, microanalysis, team sports, observation device, systematic observation.

COMPETENCIES OF FLEMISH JUDOCOACHES A AND B

CAPLIN, A., DOM, E., ZINZEN, E.

VRIJE UNIVERSITEIT BRUSSEL (VUB)

Introduction: The European parliament has been approving the European Qualification Structure (EQS). This structure consists of competencies of all jobs, classified in numbered levels (OECD, 2005). A job, described in a qualification profile, will give visible expectations and can be objectively evaluated. This study aims to determine the competencies of the judocoach and create a framework in which he/she works.

Method: The Delphi method was used to personally interview Flemish qualified judo experts (in different rounds) to ensure that all coaching views/opinions were recorded and that finally a consensus could be reached (Linstone and Turoff, 2002).

In the first round the core tasks were determined with their associated "knowledge", "skills" and "attitudes". In the second round, all listed items were located by the experts in a particular (Flemish) trainer level. From their, in the final round, the competencies (combination of

knowledge, skills and attitudes) were composed (using COMET, 2003) and proposed to the experts for confirmation in a consensus meeting.

Results: There were eight competencies formed, namely: communication, tracking changes, feedback, individualization, working pedagogic and didactic, set up plans, working in team and technical and tactical instructions. These competencies are further developed as the coach reached a higher level. The competencies are completed differently depending on the context (main task) in which the coach works. The judocoach B has six main tasks including competitive training, recreational training, coaching, mentor/supporting, information gathering and talent detection. The judocoach A has seven main tasks including competitive training, recreational training, coaching, mentor/supporting, information gathering, talent detection and sports leadership.

During the study it became apparent that the experts lacked a (higher) coachlevel to put 5 specific tasks in: competitive targeted training, coaching, supporting, information gathering and sports leadership.

Discussion/conclusion: A framework was formed combining age and level of judokas with the level of the coach (with their respective determined tasks and competencies): the young talented judoka should grow and develop on the national level with a judocoach B, whilst a judocoach A has to lead him to a high international competitive level and finally the judocoach of higher level will guide the international top athlete (World Championships, Olympics)

PARENTAL INVOLVEMENT IN YOUTH SPORT.

ROMAR, J.E., FORSBLOM, M., HÄLLUND, F.

ÅBO AKADEMI UNIVERSITY

Introduction: Parent engagement in youth sport settings has important implications for their children's experiences. Parents often assume the role of motivator, facilitator, even coach in their children's participation and success in sport. In these roles parents can provide economical, emotional, and physical support. Parents can also create stress for the young athlete in the interest of excellence and success. The purpose of this study was to examine young athletes' perceived parental involvement in Finland and Austria.

Methods

The Parental Involvement in Sport Questionnaire (PISQ) (Hinic, 2004; Wuerth & al., 2002) was administrated to 116 Finnish and to 133 Austrian young athletes ages ranging from nine to eleven years old. The instrument measured athletes' perceptions of their parents' behavior utilizing four sub-scales: Active Involvement (AI), Praise and Understanding (PU), Directive Behavior (DB) and Pressure (P).

Results: The young athletes perceived higher pressure (P) from their fathers than from their mothers. Similarly, boys perceived higher pressure (P) from their fathers and mothers than girls. Young athletes from Finland perceived higher parental active involvement (AI) and pressure (P) than athletes from Austria. On the other hand, athletes from Austria perceived higher praise and understanding (PU) than Finnish athletes.

Discussion: Parental involvment, seen as parental support and parental pressure are interesting forces in children's sport participation. This study demonstrated both gender and cultural differences for parental involvement, which need to be recognized and utilized in coach education. In addition, these findings should be disseminated to parents to initiate a discussion with parents.

OP-HF02 Health and Fitness 2

IS VIGOROUS PHYSICAL ACTIVITY A RISK FACTOR FOR PELVIC ORGAN PROLAPSE?

BRÆKKEN, I., MAJIDA, M., ELLSTRØM ENGH, M., BØ, K.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Objective: The aim of the present study was to investigate former and current physical activity as risk factors for pelvic organ prolapse (POP).

Background: It has been estimated that half of women who have given birth lose pelvic floor support, resulting in some degree of POP, and of these 10-20% will seek medical attention. To date there is scant knowledge about the impact of vigorous physical activity and the presence of POP. However high intensity training is believed to be a risk factor (1), due to its similarity to heavy physical work. Searches on PubMed revealed two studies presenting data on physical activity, and they not reveal any association between physical activity and POP.

Methods: Forty-nine women with POP were age and parity matched one-to-one with 49 controls. Questionnaire and interview covered current and former physical activity (exercise type, frequency, duration and intensity), socioeconomic status, heavy work, medical history and family history. Current and former exercise volume was estimated by multiplying exercise duration with frequency. Intensive exercise was defined as physical activity implying sweating or heavy breathing, and current exercise was classified as either high or low intensity.

Continuous data were analysed with Wilcoxon paired test, and McNemars test was used for categorical data. A special cox regression model was used to fit a conditional logistic regression procedure for one – to- one matched case-control studies

Results: Differences between cases and controls were found in former and current exercise volume of high intensity, family history of pelvic floor disorders, socioeconomic status, heavy work and body mass index (BMI) ($p<0.05$). However, the positive association with present high intensity and former exercise volume as well as family history of pelvic floor disorders found in the unadjusted analyses disappeared after adjustment for socioeconomic status and BMI. Low intensity exercise was not found to be associated with POP. When combining being a current high intensity exerciser and former exerciser, the test of trend was borderline significant ($p=0.06$). Women who never had been active compared to women who always had been exercisers had an odds ratio of 5.4 (95% CI 1.4-20.9) for POP.

Discussion: The present study revealed significantly higher former exercise volume among women with POP than age and parity matched controls. Hence, being a former exerciser is not associated with POP, and the result of this study does not support the hypothesis that vigorous physical activity is a risk factor for POP (1). The lower exercise volume of high intensity activities among women with POP compared to the controls may be due to the fact that POP is bothersome doing these kinds of activities.

Conclusion: Being a former exerciser is not associated with POP

IDENTIFYING PHYSICALLY INACTIVE YOUNG ADULTS IN FINLAND

ROVIO, E., HAKONEN, H., KANKAANPÄÄ, A., HAKAMÄKI, M., HELAKORPI, S., UUTELA, A., HAVAS, E.

LIKES RESEARCH CENTER, JYVÄSKYLÄ, FINLAND

Introduction: There is a large part of the Finnish population that does not exercise enough to maintain their health. The reasons for the insignificant (amount of) physical activity have not been specified in detail in the previous studies. The inability to involve physically inactive people, making decisions and planning exercise programs without knowing the needs and behaviours of physically inactive people, have created limitations in previous research, physical activity politics, and sport organisations. The factors that have been recognised at the whole population level do not necessarily apply to smaller inactive groups. The purpose of this study is to examine what types of inactive adult groups can be recognised based on the health behaviour research data (AVTK) of Social Institution of Finland (KELA).

Methods

The data is based on the responses to the health behaviour survey of Social Institution of Finland in 2007. There were 3245 respondents of 15-64-year-old Finns. Approximately 37% (1163) of the respondents were classified as physically inactive. Through explorative factor analysis, nine factors were created: smoking, mental health problems, illnesses, alcohol, health advancement, working time, age, education, and eating habits. Cluster analysis was used to create 14 groups of physically inactive people who differ from each other based on their way of life and health. A group of young men (n=104/9,0%) and a group of young women (n=138/11,9%) were selected as subjects in this study.

Results: The average age in the young men's (n=104/9,0%) group was 22,5 years, the majority were unmarried, studying or working, and free from illnesses or disabilities that would affect their job or exercise ability. They drank more coffee, ate more sweats and fast food, and used more alcohol than average. They were not very interested in enhancing their health.

The average age in the young women's group (n=138/11,9%) was 33,4 years. The majority were married or lived together with their partner, most of these were students, and free from illnesses or disabilities that would affect their job or exercise ability. The members of the group took care of their health by eating healthy foods, not smoking, and using less alcohol than average. They often show willingness to change their lifestyle habits and are interested in enhancing their health.

Discussion: In the present study novel groups of physically inactive people were recognised. In these groups of young men and young women physical inactivity was not linked with socioeconomic status but with the lifestyle as a whole. Physical inactivity is already part of the adolescents' culture in Finland. Recognising the specific characters of the groups enables better exercise intervention planning for physically inactive people.

GROWTH AND BONE STRENGTH IN OVERWEIGHT AND OBESE PERI-PUBERTAL BOYS AND GIRLS

BAPTISTA, F., MOURA, P., FRAGOSO, I., VIEIRA, F., BARRIGAS, C., SOUTELLO, L.

FACULTY OF HUMAN MOVEMENT, TECHNICAL UNIVERSITY OF LISBON

Introduction: A high body mass index (BMI) has been associated with a high skeletal dimension and mass in children, adolescents and young adults, and with a low rate of bone loss during aging. A previous study with overweight/obese pre-pubertal children observed, however, an insufficient femoral neck strength adaptation to an advanced general skeletal growth and development [1]. The purpose of the present investigation was, also, to analyze the influence of overweight and obesity in growth and strength of the skeleton, but in peripubertal boys and girls.

Methods: Participants were 263 adolescents, 141girls (11.1±0.1 yrs) and 122 boys (11.7±0.2 yrs), of which 235 with normal body mass index (17.0±2.1 kg/m2), and 28 overweight or obese (22.5±2.2 kg/m2) in accordance with Cole et al. (2000) criteria. The anthropometric measures obtained were: height and weight, biepicondylar humerus and biepicondylar femur breadths, and skinfolds. Fat mass percentage was estimated using the mean value of the Slaughter et al. (1988) and Lohman (1986) equations. Evaluation of radius and tibia bone speed of sound was conducted with quantitative ultrasound (Sunlight Omnisense) and physical activity (PA) with the Actigraph accelerometer (GT1M) over seven days. The outcome PA variables were the number of minutes the child engaged in activity of different intensities. Cut points of 100 and 1952 counts/min represent sedentary, light, and moderate plus vigorous PA. Pubertal maturation was assessed according secondary sex characteristics (Tanner, 1962). Bone age was determined by the Tanner-Whitehouse III Method. Energy and calcium intake were calculated from a semi-quantitative Food Frequency Questionnaire assessing regular intake of a wide set of typical Portuguese foods. ANOVA was used to analyze the main and interaction effects of BMI (with vs. without overweight/obesity) and gender (male vs. female) on the variables described.

Results: It was observed a BMI main effect with overweight/obese participants demonstrating a higher skeletal dimension in lower limbs, namely, in bi epicondylar femur breadth (9.1±0.5 vs. 8.5±0.6 cm), but a lower bone speed of sound at the tibia (3612±102 vs. 3666±113 m/s), than children without overweight/obesity. It was not observed any BMI effect in upper limbs region or in any other variable. It was also not observed any interaction between BMI and gender (boys vs. girls).

Conclusion: Overweight/obesity during peri-pubertal years appears to promote wide bones at the lower limbs region but not with adequate bone density, elasticity and internal architecture expressed by the tibia speed of sound.

EFFECTS OF MENSTRUAL CYCLE PHASE ON CARDIOPULMONARY RESPONSES IN HEALTHY ACTIVE AND INACTIVE FEMALES

MOHSENZADEH, M.

UNIVERSITY

INTRODUCTION: The effects of menstrual cycle hormones on exercise performance have been studied previously however, the results remain controversial.Particularly,the respiratory responses to progressive intensity exercise have shown inconsistent results.It is thought that the higher levels of circulating estrogen and progesterone are the stimuli for altered ventilatory responses during the luteal phase of the cycle(Sheel et al.,2004).Our purpose is to compare the cardiorespiraory responses to progressive intensity exercise during the early follicular and luteal phases of the menstrual cycle.

METHODS: Twenty healthy active and inactive Females volunteered to participate in the study.Recruitment will be limited to young(19-25 yrs)healthy female subjects with no known history of cardiopulmonary,metabolic or musculoskeletal disease who willingly volunteer to participate in this study.Furthermore, the subjects provided a blood sample for the determination of luteal phase.Progesterone and Gnadotropic concentrations were measured with commercially available double-antibody radioimmunoassay kits.An incremental graded exercise test(Hopkins et al.,2000)was conducted on a cycle ergometer in the early follicular and luteal of menstrual phase.Pulmonary function and expired gas analysis will be determined with the aid of an automated gas analyzer(model k4b2).All testing was conducted in accordance with the guidelines of the American College of Sports Medicine(2000)in the measurement center of Olympic committee.

RESULT: A repeated measures ANOVA was used to determine differences in minute ventilation,maximal heart rate, oxygen pulse,maximal oxygen uptake,respiratory exchange ratio during the follicular and luteal phases.

There are no differences in maximal exercise test variables between the follicular and luteal phases of the menstrual cycle of active and inactive females.

DISCUSSION: There were no significant differences in gas exchange variables during a maximal graded exercise test between the follicular and luteal phases of the menstrual cycle in active and inactive females. It is thought that the higher levels of circulating estrogen and progesterone are the stimuli for altered ventilatory responses during the luteal phase of the cycle(William et al.,1997).These results provide additional data suggesting that the timing of the menstrual cycle phase may not be as critical as once thought when designing future exercise ventilation studies.

HEALTH RISK BEHAVIOURS AMONG ADOLESCENT GIRLS: A QUESTIONNAIRE VS AN INTERVIEW

AFRICA, E.

STELLENBOSCH UNIVERSITY

HEALTH RISK BEHAVIOURS AMONG ADOLESCENT GIRLS: A QUESTIONNAIRE VS AN INTERVIEW

Eileen K Africa

Department of Sport Science, Stellenbosch University, Stellenbosch, South Africa

ABSTRACT

Adolescent girls grapple with life's complexities and there is considerable evidence supporting the idea that health risk behaviours amongst adolescents is mounting. These risk behaviours include violence, cigarette smoking, alcohol and drug use and abuse, irresponsible sexual behaviours, unhealthy eating behaviours and physical inactivity. The study population consisted of adolescent girls in Grade 12 (N=37) who was selected from a previously disadvantaged high school in the Worcester region, South Africa. The main aim of this article was to investigate whether the respondents were honest in completing a questionnaire based on the Youth Risk Behaviour Survey (YRBS). The reliability and validity of the YRBS has been proven by many researchers. A Kappa statistic was computed for each item of the questionnaire. Kappas ranged from 23.6% to 90.5% with a mean of 60%. For the reason that adolescents tend to purposefully under- or over report health risk behaviours because of the sensitivity of the questions, the need existed to determine if the results of a timeline follow-back (TLFB) procedure through interviews correspond with the results of the questionnaire that the participants completed. The TLFB was based on the alcohol timeline follow-back assessment method by Sobell and Sobell (1992). A TLFB procedure was used as an alternative method to determine if the respondents answered the YRBS in all honesty. In most cases the results show that the respondents were honest in answering the questionnaires and no statistical differences were detected. Seeing that there are no significant differences, the TLFB procedure can be useful in the understanding of youth risk behaviour.

FOLLOW UP OF AN ACTIVE WALKING PROGRAM ON SEDENTARY AND MODERATELY OBESE POSTMENOPAUSAL WOMEN

GARNIER, S., GAUBERT, I., AUNEAU, G., MAURIEGE, P.

UNIVERSITÉ PAUL SABATIER

Introduction: Participation to an active walking program help postmenopausal women to feel better (Lean and Lara, 2002) and improve their metabolic risk profile (Roussel et al 2009). However, these beneficial effects at long term have not been fully investigated. Aims of the present study were to examine the impact of an active walking program on cardiorespiratory fitness (CRF), body composition, two years after the intervention and to compare women who continued to walk and those who did not.

Methods: 181 initially sedentary and moderately obese (mean body mass index, BMI = 30 +- 4 kg/m2) postmenopausal women (60 +- 5 yrs-old) were subjected to a 4-month endurance-training program consisting in 3 sessions/week of 45 min-walking, at 60 % of their heart rate reserve.

During this period, women were asked to maintain their usual dietary habits.

Following measurements were performed before and and after the 4-month aerobic exercise program as well as two years later, on 95 women:

- height, weight (body mass index, BMI, calculated) and waist circumference were measured using standardized procedures,
- fat mass and fat-free mass were determined by electrical bioimpedance (Bodystat 1500),
- CRF was assessed by the 2-km walking test (Laukkanen et al., 1993) and estimated VO2max was then calculated,

41 women completed a short follow up questionnaire by phone (QP) and 45 gave up.

Results: Although 91/136 women at least continued to walk after the 4-month aerobic exercise program, this ratio was lower in the QP than in the other group (72/95 vs 19/41; p <.001). The mean weakly frequency declared was 2 and the mean subjected intensity reported was considered as «very moderate». Two years later, the decrease in body weight (p=.0001), BMI (p<.05), fat mass (p<.0001) and fitness (p<.0001) was maintained in the 95 women who completed the whole. However, the decrease in the waist circumference was not maintained (NS). Among the 95 women, those who continued to walk maintained their body weight (p=.003), BMI (p<.01), fat mass (p <.0001) and fitness (p<.0001) but not their girth waist (P=.07). These improvements did not persist on the women who stopped walking (NS) except for the level of fitness (p<.0001).

Discussion: This program let the wide majority of the initially sedentary women engage themselves on the long term in this type of physical activity and maintain benefits on health. On the opposite the women who stopped walking could not maintain all these ameliorations.

IS-SS09 Friluftsliv - the impact of outdoor education on environmental concerns

OUT-OF-DOORS AND ENCOUNTERS WITH NATURE FOR SUSTAINABLE DEVELOPMENT?

SANDELL, K.

KARLSTAD UNIVERSITY

There are various reasons for being out-of-doors and outdoor recreation as a pedagogical tool could be used for a number of aims. A recurrent theme never the less is to use outdoor education for the need of environmental concerns and try to develop environmental engagement also involving behaviour and life style issues in line with the strive for sustainable development. It is here reasonable to believe that what type of outdoor recreation activity and what pedagogical perspectives and motives that are used will be linked to different effects with regard to environmental engagement. In this presentation a mind map over outdoor recreation and environmental concerns and their interlinkages will be proposed. A division of three different types of outdoor recreation with regard to landscape relations (different 'outdoor recreation styles') and a division of two main types of motives (as a means for different purposes, and as an intrinsic value) is made. Also a division with regard to the depth of environmental concerns in terms of: nature protection, nature conservation, environmental control and sustainable development are put forward. A special focus in the presentation is the role of encounters with nature in outdoor education for sustainable development. Here six aspects of encounters with nature that describe the potential of outdoor education in a pluralistic environmental and sustainable education will be presented: I An experience-based meaning of nature; II A relational ethical perspective; III Adding a fourth perspective to sustainable development; IV Human ecology in practice; V Sensing the quality of a simple life; and VI Democracy, identity and dwelling. These six aspects have been established partly with the aid of three case practices carried out in a multidisciplinary research program in Sweden: i.e. outdoor education with roots in traditional biology excursions, outdoor activities as a means for children's development, and outdoor education connected to the radical outdoor movement.

FRILUFTSLIV AND OUTDOOR EDUCATION - THE DEEP ECOLOGICAL APPROACH

BREIVIK, G.

NORWEGIAN SCHOOL OF SPORT SCIENCES

The purpose of the paper is to present and discuss the idea of "friluftsliv" or outdoor life by focusing on Arne Næss, his ideas about deep ecology and the consequences these ideas have for outdoor education. The Norwegian word "friluftsliv" was coined by among others, Henrik Ibsen, and means literally "life in the open air". But the word is connected to certain deeper ideas and ideals (Reed & Rothenberg, 1993). Friluftsliv involves certain values, a certain ideology of being outdoors with simple means, being free and close to nature and with a

deep respect for the wilderness. Nature is thus considered a central part of the Norwegian national identity (Breivik, 1989; Reed & Rothenberg, 1993).

In the beginning of the 20th century and up towards the 1960s sport and friluftsliv seemed to flourish side by side. But old tensions surfaced in the 1960s and 1970s when elite sport developed into professional show sport. Leading friluftsliv ideologists, like Faarlund and Kvaløy Sætereng, felt that friluftsliv and sport had to split completely and that friluftsliv was the only acceptable physical culture from an ecological point of view (Faarlund, 1993; Kvaløy Sætereng, 1993).

In the 1960s and 1970s study programs in friluftsliv were developed at various university colleges in Norway. The theoretical foundation for the new area of study was sought in the new ecological disciplines and especially "deep ecology". It was Arne Næss (1912-2009) who in 1973 coined the term "deep ecology" (Næss, 1973). Later he developed his own systematic philosophical version of deep ecology called "ecosophy T" (Næss, 1990) From an ecophilosophical platform he sketched how friluftsliv should be experienced and practiced (Næss, 1994).

The paper will be divided into five sections. The first section gives a short presentation of Arne Næss, his life and philosophy. The second section examines relevant aspects of ecosophy T, especially the ideas of "self-realization" and of "increasing identification with all beings". In the third section Arne Næss' thoughts on outdoor life are presented and discussed, especially the ideas of "hilaritas" and "many-sidedness". The last section will give examples of Arne Næss' own practice and discuss implications of his philosophy for outdoor education.

NARRATIVES ON NATURE, NURTURE AND CULTURE

GURHOLT, K.P.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction: Autobiographies of prominent environmentalists show that their early lives have been rich in personal experiences of nature (Milton, 2002). Notably, the early childhood experiences of philosopher and climber Arne Næss (1912-2009) inspired the development of the philosophy of deep ecology, which influenced the emergence of friluftsliv as environmental pedagogy in the 1970's. As a subject friluftsliv was underpinned by the principle of identification with nature and consequently intended to induce people to act protectively towards nature, not because 'they think they ought to but because they feel inclined to'. This paper contributes to the understanding of complex, empathetic relationships to nature by analysing the significance of nature and friluftsliv in the life-worlds of young Norwegians.

Methods: In 2001 and 2006 nearly 200 youths aged from 15 to 19, living in the sub-Arctic, a suburb of Oslo, and a southern seaside holiday site, wrote essays on their experiences of nature. The question was an open one but stimulated a biographical approach (Gurholt, 2005; Vigane, 2007).

Results: The youth emphasise intimate experiences of nature from early childhood. These experiences are connected to playing freely in neighbourhoods and hiking with family and friends. They express a love for the native "natural world". Despite the fact that "nature means a lot", the relations to nature have at the time of writing become distanced. When looking into the future, they often dream of living close to nature, which is not seen antagonistic to urban lifestyles. If they have children, they want them to grow up with the same freedom to play outside as they themselves enjoyed in their own childhood. The youth are concerned about litter and reflect on "nature's life giving significance", often expressed abstractly as something "we must of course take care of" because "nature is the biggest reason why we humans are able to live on this planet." However, the ways in which the youth are acting towards nature, e.g. activities performed and technology used, represent broad diversity.

Discussion: Processes of self-formation nurtured by close contact with nature are discussed as embodied experiences, which in part are informed by stories on how nature is perceived and should be treated and nurtured. Recent theories on the ecological self do not take social relations into account (Milton, 2002: Sutton, 2004). This study indicates that it is the interweave of natural/ecological processes, transforming selves and socio-cultural relations that underpin young people's diverse feelings and actions towards nature, friluftsliv and environmental issues.

IS-SM03 Evidence Based Sports Physiotherapy: the difficulty of the research paradigms

THE DIFFICULTY OF THE RESEARCH PARADIGMS IN SPORTSPHYSIOTHERAPY

CABRI, J., BAEYENS, J., VIROUX, P.

FACULDADE DE MOTRICIDADE HUMANA - UTL

The application of evidence based practice is nowadays an accepted way to treat patients more effectively. Results of the latest scientific research are communicated to the health care providers, who may have to change their daily practice accordingly. However, in physiotherapy in general and in sports physiotherapy more particularly, some difficulties may arise when considering the research paradigms. Indeed, some of the assumptions researchers use (e.g. independency of observer, therapist and patient) may interact and therefore lead to research bias. Blinding, for example, may be in some cases impossible because of the interaction between the therapist-researcher and the patient. Furthermore, especially in RCT's, there is much debate about the 'standard' or 'control' therapy, because of the inexistence of the latter. Additionally, much controversy still exists with respect to the terminology used when considering joint kinematics. The invited symposium is aimed at the reflection of the aforementioned problems and exemplified by the research going on in shoulder injuries of athletes and its consequences for the practice.

FINE TUNING THE THROWING SHOULDER: BALANCING IN THE MOBILITY/STABILITY PARADOX

BAEYENS, J.P.

VRIJE UNIVERSITEIT BRUSSEL

Throwing athletes require a delicate balance of shoulder mobility and stability in order to meet the functionally high demanding loads of their throwing skills. There is evidence that shows altered mobility patterns in the throwing shoulder. In their dominant shoulder, throwers display increased external rotation and limited internal rotation, the latter hypothesized to be related to posterior shoulder tightness. The external rotation gain has been thought to be advantageous in terms of ball velocity upon release. However, the altered shoulder ROM can evolve into overuse manifestations such as subacromial impingement, internal impingement and SLAP lesions. In throwers with borderline internal impingent, glenohumeral external rotation at 90° abduction is increased as compared to asymptomatic throwers. Throwers with internal impingement also have significantly more internal rotation deficit compared with asymptomatic throwers.These rotations are coupled with obligate intra articular translatons. No significant differences in anterior translation but increased anterior stiffness in 90° external rotation at 90° abduction have been found between the throwing and non throwing shoulders in asymptomatic professional baseball pitchers. F.i. external rotation at late cocking results in posterior humeral head translation. Throwers with minimal anterior instability do not present this posterior translation. Enhanced superior translation and diminished posterior translation have been demonstrated to relate to subacromial impingement.

Scapular kinematics has been a increased area of investigation in recent years. Throwers present with augmented scapular upwards rotation, internal rotation and retraction. Increased scapular posterior tilt and upwards rotation of the scapula has been shown in throwers with internal impingement compared to non symptomatic shoulders. In subacromial impingement, decreased upwards rotation and posterior tilt have been shown. In subacromial impingement, a strengthening program accentuating on the scapular muscles proved to be efficient for upwards and internal rotation, but nor for posterior tilt.

This presentation will assess an update of the scapulothoracic arthrokinematics and the intra articular kinematics of the glenohumeral joint in context of the throwing shoulder with and without shouder problems.

FINE TUNING THE SHOULDER DURING THE PRE-SEASON CONDITIONING OF ELITE TENNIS PLAYERS; A QUESTION OF MOBILITY OR STABILITY ?

VIROUX, P.

ATHLETES CARE - SPORT MEDICAL ADVICE CENTER

When it comes to pre-season screening in function of the conditioning program to prepare elite tennis players for their tennis-season, evaluation must be done thoroughly and within the right context. Performance is the most important aspect for tennis coaches and conditioning trainers. But optimal performance can only be achieved when the athlete is injury free. As a sports physical therapist integration of a preventive strategy in this conditioning program is my main goal for my elite tennis players.

In a sport with a great biomechanical aspect like tennis, my practical work method is based upon the 'kinetic chain theory'. Basic screening of a players 'posture and movement' in relation to the players specific 'movement patterns' is the first step.

The combination of those results and the knowledge about the kinetic chain principles in tennis make it possible to integrate a preventive strategy in this pre-season conditioning program.

Evidence based principles of injury prevention let us know that evaluation of previous injuries and sport specific adaptations in relation to the known mechanisms of tennis injuries are not only important but even essential.

The very specific role of the shoulder in the kinetic chain of tennis players and the fact that shoulder injuries are still very common in elite tennis players emphasize the importance of such a very specific evaluation method. Fine tuning the shoulder can only be done if the balance between mobility and stability is reached.

This sport specific evaluation of the shoulder will be presented as well as the ' fine tuning' strategy of this link within the kinetic chain of the sport of tennis.

Invited symposia

IS-PH04 The Physiology of East and North African Runners (EFSMA Exchange Symposium)

AFRICAN RUNNERS: NATURE OR NURTURE?

DICKHUTH, H.

UNIVERSITY HOSPITAL FREIBURG

In 1985, 50% of the best runners came from Europe, 21% from Africa and about 15% from North-America. 25 years later the situation had changed completely.

We see a dramatic change in the countries of origin from which the best middle- and long-distance runners have come. Today 69% of the best runners come from Africa and 47% of these from Kenya.

The East-African countries of Ethiopia and Eritrea, as well as Morocco, are also represented in middle distance running. It is noteworthy, that in these countries we find no excellent sprinters.

On the other hand it is interesting that in 2008, the top sprinters essentially had their genetic roots in West-Africa, including those sprinters from the Caribbean and the USA. It is interesting, that it is not possible to find excellent middle- and long-distance runners in those countries.

Most of the sports medicine scientists believe that the differences in endurance and sprint performance have a genetic background. The genetic type and the phenotype of East-Africans differ considerably from those of West-Africans. An explanation for this could be a selective pressure caused by the dryness and high altitude conditions in North- and East-Africa. That would fit with the fact that the genetic exchange between East- and West-Africa was prevented by the East-African rift and by the desert (Sahara).

In conclusion, a small genetic shift might be a small genetic shift (pressure) which is responsible for the different phenotype observed of West-Africa and East-Africa.

But what are the physiological differences which allow East-African, especially Kenyan runners, to be top runners world-wide?

PHYSIOLOGICAL APPROACH OF KENYAN TRAINING

BILLAT, V.

UNIVERSITE D'EVRY VAL D'ESSONNE

Introduction: The purpose of this study was to test the hypothesis that there was no significant difference between the aerobic and anaerobic component of performance with the critical speed model and that training is responsible for two different physiological phenotypes in two groups of Kenyan runners belonging to the same ethnic group and village (Kissi).

Methods: In order to compare the aerobic and anaerobic component of the Kenyan vs. non Kenyan best performers (from 800 to 10,000m) we compared their critical velocity and anaerobic distance capacity using the critical power model with 2 components (1). VO2 was measured breath by breath using a portable gas analyser (K4b2, Cosmed) during an incremental exhaustive running test performed on a running track.

The subjects were 20 elite Kenyan runners: 13 men (10-km performance time: 10-km performance time of 28 min, 36 s ±18 s) and 7 women (32 min, 32 s ±65 s). The male runners were separated into high-speed training runners (HST: N = 6) and low-speed training runners (LST: N =7) depending on whether they train at speeds equal or higher than those associated with the maximal oxygen uptake (vVO2max). All but one woman were high-speed training runners (female HST: N =6). Subjects performed an incremental test on a 400-m track to determine VO2max, vVO2max, and the velocity at the lactate threshold (vLT).

Results: There was no significant difference of critical speed or anaerobic distance capacity between Kenyan or non Kenyan runners (21.3±0.6 vs. 22.1±0.6 km.h-1, p = 0.07) for CV and (213±68 vs. 185±69 m, p = 0.45) for ADC. Within each gender among the HST group, 10-km performance time was inversely correlated with vVO2max (rho =0.86, P =0.05, and rho =0.95, P =0.03, for men and women, respectively). HST male runners had a higher VO2max, a lower (but not significantly) fraction of vVO2max (FvVO2max) at the lactate threshold, and a higher energy cost of running (ECR). Among men, the weekly training distance at vVO2max explained 59% of the variance of vVO2max, and vVO2max explained 52% of the variance of 10-km performance time. Kenyan women had a high VO2max and FVO2max at vLT that was lower than their male HST counterparts. ECR was not significantly different between genders.

Conclusion

The critical speed, vVO2max and ADC of the Kenyan or non Kenyan top 20 best performer middle and long distance runners were not significantly different. However, ADC is only an indirect marker of anaerobic capacity which must be explored with oxygen deficit. Caucasian non Kenyan runners have a non significant higher vVO2max extrapolated from 3000m performance considering the time limit at VO2max reported in literature (7 min). Kenyan have polarized training even inside one training session and practice skills that could contribute positively to this ability for speed variation that allows for energetic optimisation (1).

KENYAN DOMINANCE IN DISTANCE RUNNING

LARSEN, H.B.

COPENHAGEN MUSCLE RESEARCH CENTRE

Abstract. During the past three decades, the international scene of middle- and long-distance running for men has been dominated by Kenyans. Critical physiological factors for performance in running are maximal oxygen consumption (VO2max), fractional Vo2max utilization and running economy. While Kenyan and Caucasian elite runners are able to reach very high, but similar maximal oxygen uptake levels, the VO2max of black South African elite runners seems to be slightly lower. Moreover, the studies of black and white South African runners indicate that the former are able to sustain the highest fraction of VO2max during long distance running. Results on adolescent Kenyan and Caucasian boys show that these boys are running at a similar percentage of VO2max during competition. A lower energy cost of running has been demonstrated in Kenyan elite runners and in untrained adolescent Kenyan boys compared to their Caucasian counterparts. In agreement with this are the results from studies of black South African elite runners who have shown similar low energy costs during running as the Kenyan elite runners. The good running economy cannot be explained by differences in muscle fibre type as they are the same in Kenyan and Caucasian runners. The same is true when comparing untrained adolescent Kenyan boys with their Caucasian counterparts. A difference exists in BMI and body shape, and the Kenyans long, slender legs could be advantageous when running as the oxygen cost when running is a function of leg mass. Studies comparing the response to training of Kenyans and Caucasians have shown similar trainability with respect to VO2max, running economy and oxidative enzymes. Taken all these data together it appears that having a good running economy may be the primary factor favouring the good performance of Kenyan endurance athletes rather than them having a higher VO2max than other elite runners. In addition, the slim body shape and low mass of the lower leg are likely contributing to the superior running economy of the Kenyan runners.

THE OXYGEN TRANSPORT SYSTEM IN KENYAN RUNNERS

SCHMIDT, W., PROMMER, N., THOMA, S., NIESS, A.

UNIVERSITY OF BAYREUTH

It is assumed that the performance dominance of East African runners is primarily due to their high VO2max, high fractional utilization of VO2max, and high running economy. Their lifelong exposure to altitude has been intensively discussed as one important reason, since haemoglobin concentration and haematocrit are slightly elevated. To explain the underlying physiological reasons previous research focused on oxygen consumption while profound data concerning the oxygen transport are, however, still missing.

We therefore investigated the essential structures of O2-transport, i.e. total haemoglobin mass (tHb-mass), blood volume (BV) and heart size, in elite Kenyan runners in a combined cross sectional and longitudinal study in order to detect de-adaptation processes of these parameters during a sojourn at near sea-level.

Ten Kenyan runners (group K; competing between 1.500m and marathon) living and training at moderate altitude (~2100m) performed a 6 week training camp at 350m in Germany. Training (volume ~210km/week) was similar to that normally performed in Kenya. tHb-mass and BV were determined using the optimized CO-rebreathing method on the first day after arrival to Germany and weekly during their whole stay at low altitude. In addition BV and haemoglobin concentration ([Hb]) were also examined before departure at altitude. VO2max was determined in three field tests and running economy in a laboratory test on a treadmill. 11 German elite runners served as a control group (group G).

The Kenyan runners had a significantly lower body mass (K 57.2 ±7.0kg; G 66.5 ±6.3kg) and BMI (K 18.5 ±0.9; G 20.4 ±0.9). Relative VO2max did not differ between the groups (K 71.5 ±5.0 ml/kg/min; G 70.7 ±3.7 ml/kg/min) and absolute VO2max did not change during the 6 weeks at low altitude. Relative tHb-mass (K 14.2 ±1.0g/kg; G 14.0 ±0.7g/kg) and BV (K 101.9 ±4.5ml/kg; G 99.6 ±5.8ml/kg) were similar in both groups but continuously decreased in K during the stay at near sea level (absolute tHb-mass from 813 ±90g to 767 ±90g, $p<0.001$; BV from 5828 ±703ml to 5513 ±708ml, $p<0.01$). [Hb] tended to decrease (-0.7 ±0.7g/dl) when commuting altitude but did not differ at near sea level between the groups (K 15.4 ±1.0g/dl, G 15.5 ±1.2g/dl). The relative heart volume was slightly lower in the Kenyan group (K 14.0 ±1.5ml/kg; G 15.2 ±2.0ml/kg) and did not change at low altitude. Running economy was higher ($p<0.05$) in K at speeds of 18km/h and above and can partly be attributed to the smaller calve circumference ($p<0.001$) and lower BMI ($p<0.001$).

In conclusion, we state that the excellent performance of Kenyan runners is not simply due to an improved oxygen transport system when compared to European runners. Although Kenyans benefit from altitude effects a lower demand of oxygen at higher speeds seems to be the essential reason for their excellent performance.

LIMITING FACTORS OF ENDURANCE PERFORMANCE

ROECKER, K.

UNIVERSITY OF FREIBURG, CENTER OF INTERNAL MEDICINE

There is recent discussion about which specific innate or acquired factors are potentially responsible for the east African dominance in long distance running - or whether social and geographical factors must be taken more into account for that predominance. Prior to any experiment, a distinct evaluation of the performance determining system is needed to answer that question from a physiologist's view.

This review describes the various domains of endurance performance determination in long distance running: Some of these domains are clearly genetically determined and fixed, others are even though genetically affected but subject to adaptive transformation via training. Structural anthropometrical or biomechanical aspects belong to the first group. All characteristics of the oxygen transport chain, metabolic aspects as glycogen storage or energy turnover pathways are in the second group. Factors of motorical efficiency and coordination are further important members of this cluster.

Thereby it is totally uncertain which factorial composition may yield maximal success in long distance running. The only evidence is that not one individual factor is relevant but many. Apart from that, we also need information about the specific responsivity of these factors to training and specific stimulation. The challenge is to identify the physiological basis for a 'talent' in such a multifactorially determined ability as long distance running. A system analysis is prerequisite for any interpretation of further physiological experiments in this field.

MUSCLES OF BODY BUILDERS ARE INTRINSICALLY STRONGER THAN THOSE OF ACTIVE UNTRAINED CONTROLS

NARICI, M.V., SEYNNES, O.R., KAMANDULIS, S., SKURVIDAS, A., BRAZAITIS, M., KAIRAITIS, R., RITTWEGER, J., ERSKINE, R., MAGANARIS, C.N.

The massive muscle hypertrophy displayed by body builders (BB) is expected to be matched by a proportionate increase in muscle force. However, a higher specific tension of type 2A and type 2X single fibres of the vastus lateralis muscle of professional BB, compared to non-training controls (CTRL), has been found (1). The present study investigated whether the greater single fibre intrinsic force was reflected by a higher force per cross-sectional (F/CSA) of the whole muscle, once accounting for differences in neural activation, muscle architecture and moment arms. Eight professional male BB (aged 29.4±5.5 years, height 177.9±4.1 cm, body mass 91.7±13.4 kg), recruited by the Lithuanian Academy of Physical Education, were compared to 12 untrained, male CTRL (aged 20.8±2.5 years, height 177.4±4.6 cm, body mass 74.8±5.6 kg). Maximum isometric torque of the knee extensors (KE) was measured by isokinetic dynamometry at 60, 70, 80, 90 deg of knee extension. Quadriceps tendon (QT) moment arm (ma) was estimated by anthropometry (2) and KE volume (Vol) was estimated from a regression between anthropometric thigh muscle plus bone Vol and MRI KE Vol (3). Fascicle length (Lf) and pennation angle of the vasti lateralis (VL), medialis (VM), intermedius (VI) and rectus femoris (RF) were measured by ultrasound at rest and at the optimum angle of KE maximum torque. KE maximum force (F) was calculated as: KE torque at the optimum angle/QTma. Physiological cross-sectional area (PCSA) of VL, VI, VM and RF was calculated as the ratio of Vol/Lf, enabling KE F/PCSA to be estimated. BB KE force, Vol and PCSA were respectively, 52.3% ($P<0.01$), 13% ($P<0.01$) and 15.5% ($P<0.01$) greater than of CTRL. After accounting for differences in agonist and antagonist muscle activation and in ma, the F/PCSA of the BB was 22.1% higher ($P<0.01$) than of CTRL. Thus skeletal muscles of professional BB seem to be intrinsically stronger than those of untrained, controls. This effect, partly explained by a greater fibre specific tension, accounts for about half of the difference in KE maximum force between BB and CTRL. Thus other factors, besides single fibre specific tension, must account for this discrepancy and amongst these, a more efficient force transmission via the extracellular matrix could play a role.

VIBRATION INDUCED SUPPRESSION OF IA AFFERENT PATHWAYS AFFECT MAXIMUM FORCE BUT NOT RATE OF FORCE DEVELOPMENT

GRUBER, M., FISCHER, C., TAUBE, W., MELNYK, M., GOLLHOFER, A.

UNIVERSITY POTSDAM AND UNIVERSITY FREIBURG

Exitatory inputs from Ia afferent pathways can contribute to homonymous muscle activity during human movement. A functional role of Ia afferent inputs during the beginning of a voluntary isometric contraction was assumed based on the fact that decreased presynaptic inhibition of Ia afferent pathways was observed prior to voluntary contractions (Hultborn et al. 1987; Meunier and Pierrot-Deseilligny 1989). In the present study we hypothesized that vibration induced suppression of Ia afferent pathways projecting to triceps surae muscles result in decreased rate of force development for maximal isometric plantarflexions.
