31 Running title: gill parasites of cichlids in the Bangweulu-Mweru ecoregion

32
33 **Abstract**

34 This study represents the first exploration of the parasite fauna of cichlid fishes in the Mweru-
35 Luapula subregion (Central Africa). Twelve species of cichlids and 14 species of Monogenea
36 from three genera (*Cichlidogyrus*, *Gyrodactylus* and *Scutogyrus*) were collected. We present a
37 first record of the gill parasite fauna of eight host species, *Oreochromis mweruensis*,
38 *Orthochromis* sp. 'Mambilima', *Sargochromis mellandi*, *Serranochromis angusticeps*, *S.*
39 *stappersii*, *S. thumbergi* and *Tylochromis mylodon*. The host range of 10 parasite species was
40 expanded. The study further includes the description of *Cichlidogyrus consobrini* sp.n. from
41 *S. mellandi* and *Orthochromis* sp. 'Mambilima'. A new morphotype of *C. halli* is
42 characterized and three species, *C. papernastrema*, *C. quaestio* and *C. zambezensis* are

1 redescrbed. Furthermore, the biodiversity and host-specificity of these parasites are compared
2 with cichlid parasites from Lake Kariba and Cameroon. Two species, including *C. consobrini*
3 sp.n. and a new morphotype of *C. halli*, are putative endemics. Additionally, the parasite
4 fauna is highly similar in species composition to Lake Kariba, but in Bangweulu-Mweru the
5 same parasite species are more host-specific, probably because of hydrogeographical
6 differences between the two regions.

1 Introduction

2 The Bangweulu-Mweru ecoregion is part of the Congo basin and covers the Southeastern part
3 of the Democratic Republic of Congo (DRC) and the Northeastern part of Zambia (Thieme *et*
4 *al.*, 2005; FEOW, 2016). It lies just north of the Zambezi-Congo watershed, but parts of the
5 ecoregion drained into the Zambezi basin from the late Tertiary (Moore & Larkin, 2001) up
6 to the Holocene (Lévêque, 1997; Key *et al.*, 2004; Katongo *et al.*, 2007; Koblmüller *et al.*,
7 2008). These historical connections are also reflected in the freshwater fish fauna, which is
8 highly similar in both basins (Van Steenberge *et al.*, 2014). The freshwater fish fauna has the
9 highest similarity with the Upper Congo, to which it currently drains (Van Steenberge *et al.*,
10 2014). The Bangweulu-Mweru region is relatively speciose and exhibits a high degree of
11 endemism relative to other freshwater ecoregions (Thieme *et al.*, 2005). The Biological
12 Distinctiveness Index of the ecoregion is globally outstanding and the Conservation Status
13 Index lists it as a first priority area (Thieme *et al.*, 2005; FEOW, 2016). Bangweulu-Mweru
14 harbours 138 fish species belonging to 58 genera and 18 families (Van Steenberge *et al.*,
15 2014). Within the ecoregion, the Mweru-Luapula subregion is the most diverse, harbouring
16 135 freshwater fish species of which 35 are endemic, with Lake Mweru and the Lower
17 Luapula being the most speciose (Van Steenberge *et al.*, 2014). In contrast, the Bangweulu-
18 Chambeshi subregion is species-poor relative to Mweru-Luapula with 93 species and a single
19 endemic species (Van Steenberge *et al.*, 2014).

20 The Cichlidae (Teleostei: Cichliformes) have the highest number of endemic species (Thieme
21 *et al.*, 2005) and, after the Cyprinidae, constitute the second most speciose family (Lévêque,
22 1997) within Bangweulu-Mweru. A typical species for the Mweru-Luapula subregion is
23 *Oreochromis mweruensis* Trewavas, 1983, occurring in the Lualaba, Luvua, Lake Mweru and
24 the Lower Luapula (Schwanck, 1994). It is closely related and morphologically similar to *O.*
25 *macrochir* (Boulenger, 1912) (Trewavas, 1983; Schwanck, 1994). Both species have an
26 allopatric distribution, with *O. macrochir* occurring in the Upper Luapula, Lake Bangweulu,
27 Chambeshi, Kafue, Kalomo, Upper Zambezi, Okavango, Cunene, Buzi and Luembe Rivers
28 (Schwanck 1994). In 1945, a few pairs of *O. mweruensis* from Mweru-Luapula were
29 introduced in the vicinity of Lubumbashi for farming purposes (Thys van den Audenaerde,
30 1988). Also *O. macrochir* was introduced in Bangweulu-Mweru (Kipopo) (De Vos *et al.*
31 2001). Both species hybridise, as discovered by Thys van den Audenaerde (1964), but were
32 classified as subspecies at the time.

33 Other common species in the region, such as *Tilapia sparrmanii* Smith, 1840 and *Coptodon*
34 *rendalli* (Boulenger, 1857), have a wider distribution. They occur in both the Congo and

1 Zambezi Basins, and as far south as the Limpopo Basin (Skelton, 2001; Schwarzer *et al.*,
2 2009; Zengeya *et al.*, 2011). The serranochromine cichlids have several representatives in
3 Bangweulu-Mweru and are speciose throughout Southern Africa (Van Steenberge *et al.*,
4 2014). They also have a complex evolutionary history (Joyce *et al.*, 2005; Katongo *et al.*,
5 2007; Koblmüller *et al.*, 2008). The Serranochromine cichlids probably migrated from the
6 Congo Basin to paleolake Makgadikgadi where they experienced an explosive radiation
7 (Joyce *et al.*, 2005). When the lake dried up, several species persisted in the Southern African
8 rivers and dispersed from there (Joyce *et al.*, 2005) into the Congo Basin (Katongo *et al.*,
9 2007) through a recent link between the basins (Lévêque, 1997; Key *et al.*, 2004).

10 In complex biogeographical situations, e.g. the dispersal of serranochromine cichlids across
11 the Zambezi-Congo watershed, hydrology and molecular markers are used as biogeographical
12 tools (Joyce *et al.*, 2005; Katongo *et al.*, 2007; Koblmüller *et al.*, 2008). Additionally, fossil
13 evidence is used for studies on a larger geographical scale and on higher taxonomical levels
14 (Murray, 2001; Sparks & Smith, 2005; Friedman *et al.*, 2013). Parasites can also function as
15 biogeographical tools for freshwater fish biogeography (Pérez-Ponce de León & Choudhury,
16 2005; Barson *et al.*, 2010; Pariselle *et al.*, 2011). Although not often used in biogeographical
17 research, monogeneans are an ideal choice as taxonomic marker. They have limited dispersal
18 capability because they are aquatic, strictly parasitic and have a direct lifecycle, thus linking
19 them strongly to the host species. Furthermore, monogeneans are the most host-specific of
20 fish parasites and very host-specific in general (Whittington *et al.*, 2000; Cribb *et al.* 2002).
21 Consequently, host species are often infected by a characteristic set of monogenean species,
22 thus providing a distinguishable feature between them.

23 The most speciose monogenean genus on African cichlids is *Cichlidogyrus* Paperna, 1960
24 (Dactylogyridae), with about 120 valid species described. It occurs solely on the gills of
25 African and Levantine cichlids, with the exception of *C. nandidae* Birgi & Lambert, 1986, *C.*
26 *inconsultans* Birgi & Lambert, 1986 and *C. amieti* Birgi & Euzet, 1983 (Pariselle & Euzet,
27 2009). The former two are found on *Polycentropsis abbreviata* Boulenger, 1901 (Nandidae)
28 and the latter on representatives of Nothobranchidae. Species of *Scutogyrus* Pariselle & Euzet,
29 1995, a closely related genus, co-occur with representatives of *Cichlidogyrus* on the gills of
30 African cichlids and comprise seven described species (Pariselle & Euzet, 2009; Pariselle *et*
31 *al.*, 2013). Representatives of both genera differ in haptor morphology. Representatives of
32 *Scutogyrus* have a winged dorsal transversal bar with two very long auricles. They also have a
33 thin oval-shaped plate associated with the ventral transverse bar (Pariselle & Euzet, 2005;
34 2009; Pariselle *et al.*, 2013). In representatives of *Cichlidogyrus* the plate and wings are

1 absent and the auricles are shorter (Pariselle & Euzet, 2009). A single exception to this is an
2 undescribed *Cichlidogyrus* representative from *Limnochromis auritus* (Boulenger, 1901)
3 collected in the Burundese part of Lake Tanganyika; it has even longer auricles than those
4 found on *Scutogyrus* representatives (Kmentová *et al.*, 2016a). Phylogenetically, *Scutogyrus*
5 forms a monophyletic clade within *Cichlidogyrus*, making the latter paraphyletic, but a formal
6 re-classification has not been carried out (Pouyaud *et al.*, 2006; Wu *et al.*, 2007; Mendlová *et*
7 *al.*, 2010; Mendlová & Šimková, 2014). The host range of species of *Scutogyrus* was limited
8 to mouth-brooding cichlids, specifically Oreochromini, but one recently-discovered species
9 was found on *Coptodon mariae* (Boulenger, 1899) (Coptodini) in Cameroon, possibly the
10 result of a host switch (Pariselle *et al.*, 2013). Another genus known to infect the gills of
11 African cichlids, *Gyrodactylus* Von Nordmann, 1832 (Gyrodactylidae), infects most fish
12 orders on most continents and comprises over 450 valid species (Shinn *et al.*, 2011;
13 Zahradníčková *et al.*, 2016). Of these species only 17 are found on African cichlids
14 (Zahradníčková *et al.*, 2016). They differ substantially from representatives of
15 Dactylogyridae, e.g. they have 16 small hooks, two large hooks with two ventral bars holding
16 them together, and a unique lifecycle that is a combination of parthenogenesis and
17 hyperviviparity (Bakke *et al.*, 2007).

18 Little is known of cichlid gill monogeneans in Bangweulu-Mweru and knowledge is limited
19 to a small-scale study in the Bangweulu wetlands, Zambia from the Bangweulu-Chambeshi
20 subregion (Vanhove *et al.*, 2013). In the rest of the Congo Basin, the majority of recent
21 reports are from Lake Tanganyika (Kmentová *et al.*, 2016b). Studies on Zambezian cichlid
22 monogeneans are limited to Douëllou (1993) and Zahradníčková *et al.* (2016). The current
23 study serves as the first report on cichlid gill monogeneans (Platyhelminthes) from the
24 Mweru-Luapula subregion (see Fig. 1 for sample sites).

25
26 To date, over 140 African cichlid monogenean species have been described reported from
27 over 100 species of cichlids (Vanhove *et al.*, 2016). Over 1100 valid African cichlid species
28 have been described (Froese & Pauly, 2016) and the species richness of monogenean gill
29 parasites is estimated higher than that of cichlids. In general it is estimated that 75,000–
30 300,000 helminth species parasitize the approximately 45,000 vertebrate species on earth
31 (Poulin & Morand, 2004). We assume that the known African cichlid monogenean species
32 only represent a small fraction of the diversity. Given that the Luapula-Mweru subregion has
33 not yet been explored for cichlid monogeneans, we hypothesize, that multiple new
34 monogenean species remain to be discovered in the region. Furthermore, it is known that the

1 ancestral character of host-specificity for representatives of *Cichlidogyrus/Scutogyrus* is
2 intermediate specialism (Mendlová & Šimková, 2014). Therefore, we hypothesize that within
3 the studied parasite fauna the host range for a single species of *Cichlidogyrus/Scutogyrus* is
4 limited to a single cichlid genus.
5
6

7 **Material and methods**

8 *Sample collection*

9 Host fish were caught with gillnets during a field expedition in the DRC from 26th August to
10 11th September, 2014. They were killed with an overdose of MS222. Fish were collected from
11 five sampling localities in the Upper Congo Basin (Fig. 1), which included riverine, small
12 lacustrine and aquaculture environments. For *Cichlidogyrus zambezensis* Douëllou, 1993
13 fresh material from the type locality and type host *Serranochromis macrocephalus* (Boulenger,
14 1899) was collected because the original materials (holotype 138HF Tg7 and vouchers 161HF
15 Tg30 and 162HF Tg31 from the Muséum national d'Histoire naturelle, MNHN, Paris, France)
16 had lost their transparency and were inadequate for morphological analysis. Therefore, fresh
17 specimens from the type locality, Lake Kariba, were used as a reference to diagnose the
18 specimens from Bangwuelu-Mweru.

19 *Sample preparation and conservation*

20 Hosts were fixed in formaldehyde and deposited in the ichthyology collection of the Royal
21 Museum for Central Africa (Tervuren, Belgium; RMCA; MRAC is the French translation and
22 is used as abbreviation for the collections), stored in denatured ethanol (70%). They were
23 identified to species level by E.J. Vreven (RMCA) and U. Schliewen (Bavarian State
24 Collection of Zoology). Before fixation of the host specimens, gills (only from the right gill
25 chamber) were dissected *in situ* and stored in 100% ethanol or investigated in the field. From
26 the gills, parasites were collected exhaustively with an entomological needle under Optika
27 ST-30-2 and WILD M5 stereomicroscopes in the field and lab, respectively. Parasites were
28 mounted on slides with water and fixed under a coverslip with Hoyer's medium. The
29 coverslips were sealed with glyceel (Bates, 1997) or D-Pex. Type material was deposited in
30 the invertebrate collection of the RMCA (MRAC), the MNHN and the Iziko South African
31 museum (Cape Town, South Africa; SAMC). Voucher specimens of *Cichlidogyrus* spp. were
32 deposited under accession numbers 37980–38171, *Scutogyrus* spp. 38714–38722 and
33 *Gyrodactylus* spp. 38723–38740 in the invertebrate collection of the RMCA. Symbiotype and
34 host vouchers were deposited in the ichthyology collection of the RMCA under collection

1 2016-15-P. Note that the authors of the new taxon are different from the authors of this paper;
2 see article 50.1, recommendation 50A and 51E of the International Code of Zoological
3 Nomenclature (ICZN, 1999: Article 50.1, recommendation 50A and 51E).

5 *Microscopy and illustration*

6 The mounted specimens were diagnosed through a Leitz Dialux 22 microscope with
7 differential interference contrast and measured with Auto-montage software. Images were
8 taken with an optical camera on a Leica DM2500 microscope with Leica Application Suite
9 software, unless noted otherwise. Specimens were measured following the methods by
10 Douëllou (1993) and Fannes *et al.* (2017). The total length of the animal, 23 haptoral
11 characters, the heel, penis, accessory piece of the male copulatory organ (MCO) and the
12 vagina were measured. Illustrations were drawn freehand using a drawing tube and finalized
13 with GIMP V2.8. Filaments associated with uncinuli and anchors are not represented.

15 **Results**

16 Twelve species species of cichlids, 104 individuals and 14 species of Monogenea, 552
17 individuals, were collected. Eight host species, *O. mweruensis*, *Orthochromis* sp.
18 ‘Mambilima’ (see Schedel *et al.*, 2014), *Sargochromis mellandi* (Boulenger, 1905),
19 *Serranochromis angusticeps* (Boulenger, 1907), *S. stappersii* Trewavas, 1964, *S. thumbergi*
20 (Castelnau, 1861) and *Tylochromis mylodon* Regan, 1920, received their first gill parasite
21 screening (Table 1). For 10 parasite species the host range was expanded, most notably,
22 *Cichlidogyrus papernastrema* Price, Peebles and Bamford 1969 which is now found on *C.*
23 *rendalli*, *O. mweruensis* in addition to *T. sparrmanii*, making it a generalist species following
24 the terminology of Mendlová & Šimková (2014). Another generalist is *Gyrodactylus nyanzae*
25 Paperna, 1973, which was found on *C. rendalli* and *O. mweruensis*. This parasite was
26 previously collected from *C. rendalli* and *O. niloticus* from the Zambezi Basin
27 (Zahradníčková *et al.*, 2016), Zimbabwe and from *O. variabilis* (Boulenger, 1906) from the
28 Ugandese part of Lake Victoria (Paperna, 1973). Eleven of the collected parasite species are
29 either intermediate generalists or generalists (Table 1). Regarding host species, *O. mweruensis*
30 has the most diverse parasite fauna, with nine parasite species from three genera, while
31 *Pseudocrenilabrus philander* (Weber, 1897) is infected by a single species, *C. philander*
32 Douëllou, 1993 (Table 2). Our results further include one new parasite species, three new
33 cases of intraspecific variation and three redescriptions.

1 *Taxonomic account*

2 Cichlidogyrus consobrini *Jorissen, Pariselle and Vanhove* sp.n. (Fig. 2; 3a,b).

3 *Type host.* *S. mellandi*.

4 *Additional host.* *Orthochromis*. sp. ‘Mambilima’.

5 *Infection site.* Gills.

6 *Type locality.* Kipopo INERA aquaculture station (INERA = Institut National pour l'Etude et
7 la Recherche Agronomiques) (11°34'S 27°21"E).

8 *Other localities.* Kiswishi River near Futuka Farm on *S. mellandi* and *Orthochromis*. sp.
9 ‘Mambilima’ (11°29'S 27°39'E); Luapula River off Kashobwe on *S. mellandi* (09°40'S
10 28°37'E) (Table 2).

11 *Material studied.* 11 specimens.

12 *Type material. Holotype:* MRAC 37980 *paratypes:* six in the RMCA 37980–379082, 37993,
13 38001–38002, two in the MNHN xxxx and two in the SAMC under A088908.

14 *Symbiotype.* MRAC 2016-15-P tag 2661.

15 *Etymology.* The species epithet is derived from the Latin “consobrinus” (cousin) and is a noun
16 in apposition of the second declension in the plural form of the nominative. It honours
17 ‘Neveneffecten’, a cabaret quartet with members who are all relatives, and in particular
18 Lieven Scheire for his efforts towards popularizing science.

19 *Description.* Monogenean on average 575 µm long. Dorsal and ventral anchors small (a<40
20 µm) and in several specimens, fenestrated. Dorsal anchors strongly asymmetrical as the guard
21 length is 3–4 times the shaft length. Dorsal anchors with V-shaped indentation in the base.
22 Blade curved and short as the distal tip does not surpass the guard laterally. Dorsal transverse
23 bar slightly concave with developed auricles. Ventral anchors 1–5 µm larger than dorsal ones,
24 with a more symmetrical base and a longer, more pronouncedly-curved blade that surpasses
25 the guard laterally. Indentation U shaped. Ventral transverse bar V shaped and simple.
26 Uncinuli short (<1.7 times the length of uncinuli pair II *sensu* Pariselle & Euzet, 2009). Penis
27 is a simple, thick-walled, slightly-curved tube with a rounded basal bulb. A rectangular heel is
28 attached to the side of the basal bulb. The accessory piece crosses the penis and is attached to
29 it at the distal side of the basal bulb. It is a slightly curved tubular structure with at the distal
30 end a broad sickle-shaped hook. At the base of this hook there is a knob-shaped structure with

1 a groove in the middle. This structure protrudes and continues as a secondary tube within the
2 accessory tube (Fig. 2, 3b).

3 *Remarks.* The general shape of the MCO is reminiscent of *C. haplochromii* Paperna and
4 Thurston, 1969. Following Vignon *et al.* (2011) both species belong to group A in the genus,
5 because they possess seven pairs of small uncinuli. Furthermore, in the redescription of *C.*
6 *haplochromii*, Douëllou (1993) mentioned that the accessory piece ends in a massive hook
7 beyond the end of the copulatory tube, as is the case in *C. consobrini* sp.n. However, there are
8 differences between both species. *Cichlidogyrus haplochromii* is mostly known from species
9 of *Haplochromis*, but has never been recorded on *Sargochromis* (Pariselle & Euzet, 2009).
10 Morphologically, *C. haplochromii* possesses less asymmetrical and less deeply indented
11 anchors than *C. consobrini* sp.n. and *C. haplochromii* lacks a heel, while *C. consobrini* sp.n.
12 does possess one. Furthermore, the ventral transversal bar of *C. consobrini* sp.n. is twice as
13 long and thick as in *C. haplochromii* (56 vs. 27µm), the auricles of the dorsal bar are over
14 twice as long (22 vs. 8µm), and the dorsal transversal bar is also a lot longer (48 vs. 26µm)
15 (Douëllou, 1993). Based on these differences we consider *C. consobrini* sp.n. a different
16 species from *C. haplochromii*. Douëllou (1993) mentioned that *C. haplochromii* is probably a
17 species complex based on variations in the ventral transverse bar, but did not specify the
18 variations.

19 *Cichlidogyrus halli* Price & Kirk, 1967 species complex (Fig. 3c,d; 4).

20 *Type host.* *Tilapia shirana* (Boulenger, 1897) (now *Oreochromis shiranus* Boulenger, 1897).

21 *Infection site.* Gills.

22 *Type locality.* Fort Johnston, Upper Shire River, Malawi.

23 *Other localities.* Luapula River off Kashobwe (09°40'S 28°37'E) on *O. mweruensis* (this
24 study); Kipopo INERA aquaculture station, (11°34'S 27°21"E) on *O. mweruensis* (Table 2;
25 this study). Ouémé and Couffo, Benin on *Sarotherodon melanotheron* Rüppel, 1852 (Pariselle
26 & Euzet, 2009); Lake Albert, Lake Edward, Lake George and Kajansi fish ponds, Uganda on
27 *O. niloticus* (Linnaeus, 1758) (Pariselle & Euzet, 2009); Lake Victoria, Entebbe and Jinja,
28 Uganda on *O. variabilis* (Boulenger, 1906) (Pariselle & Euzet, 2009); Lake Kariba,
29 Zimbabwe on *O. mortimeri* (Trewavas, 1966) and *S. macrocephalus* (Pariselle & Euzet, 2009);
30 Guinea and Sierra Leone on *Sarotherodon occidentalis* (Daget, 1962) (Pariselle & Euzet,
31 2009); Lake Albert, Uganda, Lake Volta and lower Volta River, Ghana on *S. galilaeus*
32 (Linnaeus, 1758) (Pariselle & Euzet, 2009); Lake Albert and Lake George, Uganda (Pariselle
33 & Euzet, 2009) and Lake Naivasha, Kenya on *O. leucostictus* (Trewavas, 1933) (Mogoi

1 Rindoria *et al.*, 2016); Nwanedi-Luphephe dams, Limpopo River, South-Africa on *O.*
2 *mossambicus* (Peters, 1852) (Madanire-Moyo *et al.*, 2012); Lake Tana, Ethiopia on *O.*
3 *niloticus tana* (Beletew *et al.*, 2016); Kalemie, Lake Tanganyika, DRC on *O. tanganicæ*
4 (Gunther, 1894) (Muterezi Bukinga *et al.*, 2012); Nyangara wetlands, DRC on *O. niloticus*
5 (Muterezi Bukinga *et al.*, 2012) and introduced on other continents e.g. Perak, Malaysia on
6 *O. niloticus* and *Oreochromis* spp. ‘red hybrid tilapia’ (Lim *et al.*, 2016); Água Vermelha
7 Reservoir, Southeastern Brazil on *O. niloticus* (Zago *et al.*, 2014).

8 *Material studied.* Seven specimens from Kipopo INERA aquaculture station and five
9 specimens from the Luapula River (Table 2).

10
11 *Remarks.* From *O. mweruensis* two morphotypes of *C. halli* were collected. The first
12 corresponds well with the original description (Price & Kirk, 1967) and is present in the
13 INERA aquaculture station. Morphotype 2 was only found in the Lower Luapula River and
14 differs in haptor morphology compared with the other specimens. The dorsal anchors are on
15 average 12 µm smaller than the ventral ones, while in other representatives of *C. halli* both
16 pairs of anchors are of comparable size. Furthermore, the ventral bar is much longer (79 vs.
17 66 µm). Lastly, the uncinuli of pair I are smaller (15 vs. 19 µm; Table 3). All other sclerotized
18 elements of the specimens from the Luapula River match with the description of *C. halli*. We
19 observe that *C. halli* is a morphologically variable species; subspecies have been defined in
20 the past (Paperna, 1979), but have since been synonymized by Pariselle & Euzet (2009).
21 However, more work on this species complex needs to be done with special attention paid to
22 identifying possible cryptic species backed by genetic data. Preliminary studies have
23 confirmed that *C. halli* consists of different genetic strains. However, species have not been
24 formally delineated (Pouyaud *et al.*, 2006; Mendlová & Šimková, 2012). Therefore, we
25 refrain from officially describing this morphotype as a separate species until this is supported
26 by genetic data. Our decision is also based on the fact that no representative of *Cichlidogyrus*
27 has been described solely based on morphological differences in haptor structure, while no
28 morphological differences are apparent on the MCOs of the two morphotypes.

29
30 *C. papernastrema* (Fig. 5;6a,b,c).

31 *Type host.* *T. sparrmanii*.

1 *Infection site.* Gills.

2 *Type locality.* Ingwauana, Natal, Republic of South Africa.

3 *Other localities.* Futuka Farm on *T. sparrmanii* (11°29'S 27°39'E) (this study); Luapula River
4 off Kashobwe on *T. sparrmanii* (09°40'S 28°37'E) (this study); Kipopo INERA aquaculture
5 station on *C. rendalli*, *O. mweruensis* and *T. sparrmanii* (11°34'S 27°21"E) (this study); Lake
6 Kipopo on *C. rendalli* and *T. sparrmanii* (11°34'S 27°21"E) (this study); Lubumbashi Zoo on
7 *T. sparrmanii* (11°39'S 27°28'E) (this study); Bumaki Farm on *T. sparrmanii* (11°34"S
8 27°30'E) (Table 2, this study).

9 *Material studied.* Seventy mounted specimens from fresh material and one holotype.

10 *Type material. Holotype:* USNM 1366817 (Parasite collection, Smithsonian Institute)

11 *Paratypes:* Six in personal collection of original authors.

12 *Redescription.* Small to medium-sized representative of *Cichlidogyrus*, on average 351 µm
13 long. Dorsal anchors arched with a strongly-asymmetrical base. Guard length approximately
14 thrice the shaft length. Indentation of the base deep, sharp and asymmetrical with one long,
15 curved side towards the guard and one short, straight side to the shaft. Ventral anchors about
16 the same size as the dorsal ones, but with shallower V-shaped indentation and more
17 symmetrical at the base: guard about twice as long as the shaft. Dorsal transverse bar with
18 well-developed auricles. Ventral transverse bar simple, V-shaped, slightly thickened at mid-
19 length of each arm. Uncinuli pair I elongated and thick. Uncinuli pairs III-VII short. MCO
20 consists of a penis with a heel and an accessory piece that is longer than the penis itself.
21 Latero-proximally at the basal bulb a heel is attached, which is shaped like a bulge, sometimes
22 also broadened. The penis narrows slightly at the distal end of the basal bulb, after which it
23 broadens again to the same width as the basal bulb. The penis then again narrows and curves
24 towards a sharp end. The accessory piece is attached to the distal end of the basal bulb and
25 starts as a narrow tube under the penis. Where the penis curves, the accessory piece broadens.
26 More distally, the accessory piece turns towards the penis and ends in a hook. The vagina is
27 not sclerotized.

28 *Remarks.* Since the original description of *C. papernastrema* in 1969, there have been no new
29 records of this parasite. The newly-collected specimens differed in some parts from the
30 holotype (Price *et al.*, 1969). The accessory piece does not connect to the basal bulb in the
31 holotype, while all collected specimens do have this connection. Probably, the accessory piece

1 was detached from the basal bulb due to the flattening of the holotype during mounting. In
2 turn this has moved the accessory piece and flattened the penis, giving it a broader appearance.
3 Secondly, in the original description the presence of a heel was not mentioned. Detailed
4 examination of the holotype, did however, reveal the presence of such a heel. The placement
5 of the heel on the basal bulb was consistent among specimens and also on the holotype. This
6 heel is connected to a proximally closed basal bulb, which is depicted as open on the proximal
7 side in the figures of the original description. Because the morphology, measurements (Table
8 4) and host species of our collected specimens coincide with the holotype, we consider them
9 conspecific. Among recent specimens a slight variation in measurements between individuals
10 from different host species was observed. Specimens from *O. mweruensis* were consistently
11 smaller in total length, size of anchors and bars, while one specimen from *C. rendalli* was
12 much larger than all other collected specimens in total length, size of anchors and bars.
13 Possibly, this is intraspecific variation influenced by host species. The only further difference
14 we noticed was that the shaft of the ventral anchors is slightly shorter in our collected
15 specimens than in the holotype (Table 4).

16 *Cichlidogyrus quaestio* Douëllou, 1993 (Fig. 6 d,e;7).

17 *Type host.* *Tilapia rendalli* Boulenger, 1897 (now *C. rendalli* (Boulenger, 1897)).

18 *Additional hosts.* *Sargochromis codringtonii* (Boulenger, 1908), *S. macrocephalus*, *T.*
19 *sparrmanii*.

20 *Infection site.* Gills.

21 *Type locality.* Lake Kariba, Zimbabwe.

22 *Other localities.* Lake Kipopo on *C. rendalli* (11°34'S 27°21'E); Kipopo, INERA aquaculture
23 station on *C. rendalli* (11°34'S 27°21'E) (this study); Futuka Farm on *C. rendalli* and *T.*
24 *sparrmanii* (11°29'S 27°39'E) (this study); Luapula River off Kashobwe on *C. rendalli*
25 (09°40'S 28°37'E) (Table 2; this study) and Fiwili settlement, Bangweulu Wetlands, Zambia
26 from *C. rendalli* and *T. sparrmanii* (Vanhove *et al.*, 2013).

27 *Material studied.* 108 specimens.

28 *Type material.* *Holotype:* MNHN 137 HF.

29 *Redescription.* Small dactylogyridean monogenean, on average 300 µm long. Dorsal and
30 ventral anchors of similar size. Ventral anchors on average 4 µm shorter than dorsal ones.
31 Dorsal anchors asymmetrical with a guard length four to five times the shaft length and a V-

1 shaped indentation at the base. Blade curved, but subtly interrupted by an angle in the middle.
2 Dorsal transverse bar simple, slightly concave with well-developed auricles. Ventral anchors
3 more symmetrical, with a shallower V-shaped indentation and broader base than the dorsal
4 anchors. Blade crescent shaped and with longer point than the blade of the dorsal anchors.
5 Ventral transverse bar V-shaped. Arms thickest at mid-length and thinnest where both arms
6 meet. Distal end of each arm rounded and slightly thickened. At 1/3 from the distal end a
7 flattened rim is present. Uncinuli pair I long, III to VII short (*sensu* Pariselle & Euzet 2003;
8 2009). Penis thin, tubular, slightly curved. The basal bulb is oval shaped but has an
9 indentation opposite to where the penis continues. At the distal part of the basal bulb an
10 elongated rectangular heel is present. The accessory piece connects to the basal bulb, is thin
11 and longer than the penis. At 4/5 of its length the accessory piece abruptly broadens and forms
12 a hook as a tip. Vagina not sclerotized.

13 *Remarks.* Because uncinuli pair I are long and pairs III to VII short (*sensu* Pariselle & Euzet
14 2003; 2009) *C. quaestio* belongs to group B within the genus (*sensu* Vignon *et al.*, 2011).
15 Within this group *C. berradae* Pariselle & Euzet 2003, *C. digitatus* Dossou 1982, *C. quaestio*
16 and *C. yanni* Pariselle & Euzet 1996 have multiple features in common. Firstly, all species
17 occur predominantly on species of *Coptodon* Gervais 1853, but not exclusively, since *C.*
18 *berradae* can occur on *Pelmatolapia cabrae* (Boulenger, 1899) and *C. digitatus* on “*Tilapia*”
19 *brevimanus* Boulenger, 1911 as well (Pariselle & Euzet, 2009; host taxonomy taken from
20 Dunz & Schliewen, 2012, representatives of *Tilapia* belonging to Gobiocichlini are under
21 revision and mentioned within quotation marks). Secondly, in all these species the guard and
22 shaft of the dorsal anchors are asymmetrical. Furthermore, the curvature of the dorsal blade is
23 interrupted by an angle, while the ventral anchors are more symmetrical and have a
24 continuous crescent-shaped blade. The dorsal transverse bar is concave and quite thick. The
25 MCOs all have an elongated heel, a slender and simple tubular penis and an accessory piece
26 that is a bit longer than the penis and ends in a long hook. The ventral and dorsal bar, the
27 auricles and uncinuli I of *C. quaestio* are larger than those of *C. berradae*, *C. digitatus* and *C.*
28 *yanni*, while the penis is shorter. Furthermore, among these four species, *C. quaestio* is the
29 only species that has a straight and rectangular heel. Also, the accessory piece of *C. quaestio*
30 is more slender and the accessory tip is unique because the base of the hook is broadened and
31 gradually narrows in a longer curve than the others. Lastly, the basal bulb of *C. quaestio* is
32 unique in its morphology in that it has an oval-shaped indentation.

1 The differences with the original description (Douëllou, 1993) are predominantly found on the
2 MCO. Firstly, on the original drawing the attachment of the accessory piece with the basal
3 bulb was not represented and the basal bulb lacked the indentation. Furthermore, the heel is
4 shorter and more rounded in the original description. Lastly, the primary shafts of uncinuli
5 pair I are not as broad as represented on the original drawing.

6 *Cichlidogyrus papernastrema* and *C. quaestio* co-occur on *C. rendalli* and *T. sparrmanii* and
7 can be hard to distinguish since both have long uncinuli pair I, short uncinuli pairs III-VII and
8 an MCO in which the accessory piece is longer than the penis. However, the primary shaft
9 (*sensu* Pariselle & Euzet, 2003) of uncinuli pair I is thicker and larger in *C. quaestio* than in *C.*
10 *papernastrema*. Furthermore, the shape of the basal bulb of *C. quaestio* is sufficiently
11 characteristic to differentiate it from *C. papernastrema*. The basal bulb of *C. papernastrema*
12 lacks the indentation that is present in the basal bulb of *C. quaestio*. Also, the position of the
13 heel is different as in *C. quaestio* it is at the distal end of the basal bulb and in *C.*
14 *papernastrema* it is located more laterally. Lastly, the blades of the ventral anchors in *C.*
15 *quaestio* are more pronounced and have a longer crescent-shaped point than do those of *C.*
16 *papernastrema*.

17 *Cichlidogyrus zambezensis* Douëllou, 1993 (Fig. 8; 9a,b).

18 *Type host.* *S. macrocephalus*.

19 *Additional hosts.* *O. mortimeri*; *Serranochromis robustus jallae* (Günther, 1864); *S. mellandi*;
20 *S. stappersii*; *S. thumbergi*; *S. angusticeps*.

21 *Infection site.* Gills.

22 *Type locality.* Lake Kariba, Zimbabwe.

23 *Other localities.* Lake Kipopo on *S. macrocephalus* (11°34'S 27°21'E) (this study); Kipopo,
24 INERA aquaculture station on *S. mellandi* and *S. thumbergi* (11°34'S 27°21'E) (this study);
25 Futuka Farm on *S. mellandi* (11°29'S 27°39'E) (this study); Kiswishi River near Futuka on *S.*
26 *mellandi* (11°29'S 27°39'E) (this study); Luapula River off Kashobwe on *S. mellandi*, *S.*
27 *angusticeps*, *S. macrocephalus* and *S. stappersii* (09°40'S 28°37'E) (Table 2; this study);
28 Fiwili settlement, Bangweulu Wetlands, Zambia from *S. robustus jallae* (Vanhove *et al.*,
29 2013).

30 *Material studied.* 92 fresh specimens from Bangweulu-Mweru, 1 holotype and 42 vouchers
31 from Lake Kariba (MNHN 138HF, 161HF, 162HF), 5 vouchers of a 2010 expedition in

1 Bangweulu Wetlands, Zambia (MT.37714) and 32 freshly collected specimens from Lake
2 Kariba.

3 *Type material. Holotype.* MNHN 138 HF.

4 *Redescription.* Monogenean between 300–600 µm long. Ventral anchors more slender root
5 than dorsal ones with a slightly asymmetrical indentation. Blade continuous. Dorsal anchors
6 strongly asymmetrical with a guard double to quadruple the length of the shaft. Blade bent
7 more than the ventral anchors' blade. Dorsal transverse bent with long auricles. Ventral
8 transverse bar simple, V-shaped with an extension at 1/3 from where both arms meet.
9 Uncinuli pairs I–VII short (*sensu* Pariselle & Euzet 2003; 2009). The MCO consists of a
10 thick-walled penis with a well-developed swollen portion, a small basal bulb, and a narrow S-
11 shaped distal end. A heel engulfs the basal bulb and is irregular in shape, broad and short. The
12 accessory piece is often larger than the penis and is a curved tubular structure with a
13 fingerlike extension at the distal end. Proximally the accessory piece crosses the penis after
14 which it connects to the basal bulb. The sclerotized vagina is small, thick walled, triangular,
15 funnel shaped.

16 *Remarks.* Douëllou described this species in 1993 from Lake Kariba from *S. macrocephalus*
17 and *O. mortimeri*. Additional specimens from *S. robustus jallae* were collected from Fiwili
18 settlement, Bangweulu Wetlands, Zambia in 2010 (Vanhove *et al.*, 2013). Both articles report
19 morphological variation, which was considered intraspecific by the authors, and a possible
20 broad geographical and host range. However, freshly collected specimens from Bangweulu-
21 Mweru and from the type locality, Lake Kariba, differed from the original drawing and
22 measurements.

23 The major difference from the original drawing is that in all but a single specimen (from Lake
24 Kariba) the swollen portion of the penis is much larger than originally drawn. Furthermore,
25 Douëllou (1993) states that *C. papernastrema* and *C. zambezensis* are the only representatives
26 of *Cichlidogyrus* with an accessory piece that is not connected to the basal bulb. However,
27 (see remarks on *C. papernastrema* above) we have observed this connection in both species.
28 In some specimens, the accessory piece appears to be segregated from the basal bulb but in
29 others it is clearly continuous. Furthermore, in specimens where the accessory piece is split
30 off, a very thin connection between the piece and the bulb is still visible, and also a part of the
31 basal bulb points towards the distal end of the accessory piece. The accessory piece is
32 connected to the basal bulb and does not articulate with the penis as stated in Douëllou (1993).
33 Also, uncinuli I appear with a slightly longer shaft than originally drawn; the ventral anchors

1 are a bit more slender and the dorsal anchors do not always have such a pronouncedly
2 asymmetrical guard as on the original drawing.

3 A few differences in measurements between the freshly collected specimens from
4 Bangweulu-Mweru and Lake Kariba were observed. Firstly, both the ventral and dorsal
5 transverse bars as well as the auricles are larger in specimens from Bangweulu-Mweru. The
6 accessory piece is smaller in specimens from Lake Kariba (Table 6). These differences
7 between the two localities can be explained by stochastic effects, geographical variation or
8 host adaptation. However, the measurements of these specimens from *S. macrocephalus* from
9 both regions correspond with each other, which may point to differences in the size of
10 sclerotized elements due to adaptation to the host.

11 Lastly, *C. zambezensis* is a species similar in morphology to all congeners typically infecting
12 representatives of Haplochromini: it has a simple MCO, short uncinuli, an asymmetry
13 between dorsal and ventral anchors and well-developed but normal-sized auricles (Pouyaud *et*
14 *al.*, 2006; Gillardin *et al.*, 2012; Muterezi Bukinga *et al.*, 2012). Other haplochromine-
15 infecting species are e.g. *C. gillardinae* Muterezi Bukinga, Vanhove, Van Steenberge and
16 Pariselle, *C. irenae* Gillardin, Vanhove, Pariselle, Huyse and Volckaert, 2012 and *C. karibae*
17 Douëllou, 1993; the latter two also have a swollen penis. However, *C. zambezensis* is the only
18 species in this group with a sclerotized vagina and thus is distinct from the others.

19 *Cichlidogyrus* sp. (Fig. 6f).

20 *Host.* *T. mylodon*.

21 *Infection site.* Gills.

22 *Locality.* Luapula River off Kashobwe (09°40'S 28°37'E).

23 *Material studied.* 3 mounted specimens.

24 *Remarks.* From *T. mylodon*, three parasites were collected with a haptoral morphology that
25 corresponds with species of *Cichlidogyrus* infecting representatives of *Tylochromis* (see
26 Pariselle *et al.*, 2014b). The ventral transversal bar is simple and V-shaped while the dorsal
27 transversal bar has reduced auricles, similar to *C. berrebii* Pariselle & Euzet 1994.
28 Furthermore uncinuli pairs III-VII are short. Because species of *Cichlidogyrus* from *T.*
29 *mylodon* have not been studied yet it is possible that the specimens found here belong to an

1 undescribed species. However, this cannot be assessed with the material available. Because in
2 none of the three specimens the MCO was visible, they could not be identified to species level.

3 4 **Discussion**

5 *Diversity*

6 During our study, 14 monogenean species were recovered from a total of 12 host species. The
7 cichlid species with the highest monogenean species richness was *O. mweruensis*; nine
8 species of monogeneans were found. Representatives of *Oreochromis* tend to have a high
9 number of monogenean species on their gills, e.g. *O. niloticus* and *O. mortimeri* with seven
10 and eight species respectively (Douëllou, 1993; Pariselle & Euzet, 2009). Several
11 representatives of *Cichlidogyrus* and all but one species of *Scutogyrus* infect multiple species
12 of *Oreochromis* and *Sarotherodon* exclusively (Pariselle & Euzet, 2009), which are two
13 closely related mouth-brooding cichlid genera, belonging to Oreochromini (Schwarzer *et al.*,
14 2009; Dunz & Schlieuwen, 2012). Hence, one might refer to a monogenean gill fauna typical
15 of Oreochromini. In our study, the parasite fauna of *O. mweruensis* comprised of typical
16 parasite species of Oreochromini such as *C. sclerosus* Paperna & Thurston, 1969, *C. cirratus*
17 Paperna, 1964, *C. tilapiae* Paperna, 1960, *C. halli* and *S. gravivaginus* (Paperna & Thurston,
18 1969). Other typical species are all representatives of *Scutogyrus*, except for *S. vanhovei*
19 Pariselle, Bitja Nyom & Bilong Bilong, 2013. In addition, the generalist *C. papernastrema*
20 was also found on *O. mweruensis*. In contrast to the diverse gill parasite fauna of *O.*
21 *mweruensis*, the gills of the four representatives of *Serranochromis* were infected by a single
22 monogenean species, *C. zambezensis*. One of these representatives, *S. macrocephalus* is
23 known to host five parasite species in Lake Kariba, all of which are also found in the Mweru-
24 Luapula area. These are *C. dossoui*, *C. quaestio*, *C. zambezensis*, *C. sclerosus* and *C. halli*, the
25 latter two of which occur only occasionally on representatives of *Serranochromis* (Douëllou,
26 1993). However, in Bangwuelu-Mweru only *C. zambezensis* was found to infect this fish
27 (Vanhove *et al.*, 2013; *nobis*). This is likely the result of sampling bias. For *C. rendalli* and *T.*
28 *sparrmanii* the same gill parasite fauna was observed in both Mweru-Luapula and
29 Bangwuelu-Chambeshi (Vanhove *et al.*, 2013). The only difference was that *C. tiberianus*
30 was not found on *T. sparrmanii* in the Mweru-Luapula area. However, we suspect that *C.*
31 *tiberianus* does occur here on *T. sparrmanii*, but was not found due to sampling bias.
32 Furthermore, no species of *Gyrodactylus* were found on representatives of *Serranochromis*,
33 which corresponds with the results from Zahradníčková *et al.* (2016). In our study, *G.*
34 *nyanzae* was the only representative of *Gyrodactylus* on *C. rendalli*, while in the study of

1 Zahradníčková *et al.* (2016) the fauna of *C. rendalli* was dominated by *G. chitandiri*
2 Zahradníčková, Barson, Luus-Powell & Přikrylová, 2016. The Bangweulu-Mweru region is
3 situated in-between the other known localities where *G. nyanzae* occurs. It possibly has a
4 continuous distribution from central to southern Africa living on *C. rendalli* and
5 representatives of *Oreochromis* within this range.
6

7 Of the 14 parasite species, *C. consobrini* sp.n. was described; one new morphotype of *C. halli*
8 was characterised and three cases of intraspecific morphological variation were discussed.
9 Furthermore, one *Cichlidogyrus* species living on the gills of *T. mylodon* was not identified to
10 species level due to the insufficient quality of the collected specimens; it possibly represented
11 an undescribed species as this host species has not been sampled for parasites before. All
12 other recorded species were already known. This study reported a relatively low number of
13 new species for a sampling of an almost unexplored ecoregion. Most of the parasites found
14 have already been described from Lake Kariba, Zambezi Basin (Douëllou, 1993). This
15 outcome reflects the hydrological history of the ecoregion with frequent connections between
16 the Congo and Zambezi rivers (Lévêque, 1997; Moore & Larkin, 2001; Key *et al.*, 2004;
17 Katongo *et al.*, 2007; Koblmüller *et al.*, 2008). However, more sampling in the Lower
18 Luapula River and Lake Mweru would be interesting, since more endemic cichlid species are
19 present there (Van Steenberge *et al.*, 2014) and have not previously been screened for
20 parasites. Additionally, investigation in the Bangweulu-Mweru ecoregion may be useful to
21 determine to what extent the parasite fauna is a reflection of the distribution of its hosts.
22

23 *Host-specificity and biogeography*

24 The parasites found in Bangweulu-Mweru range from strict specialists to generalists
25 (following Mendlová & Šimková, 2014) (Table 1). Only one strict specialist, *C. philander*,
26 was found in this study; occurring on *P. philander* (Pariselle & Euzet, 2009). A species for
27 which the reported host range was remarkably increased is *C. papernastrema*, which was
28 previously known as a strict specialist, but is now found to be a generalist. This illustrates
29 how understudied some of these parasite species are. However, in general the host range of
30 these parasite species in Bangweulu-Mweru is found to be narrower compared with Lake
31 Kariba. This trend is most distinct for parasites from *O. mortimeri* and *S. macrocephalus*. In
32 Lake Kariba, these hosts are both infected by *C. dossoui*, *C. halli*, *C. sclerosus* and *C.*
33 *zambezensis* (Douëllou, 1993). All four of these parasite species also occur in Bangweulu-
34 Mweru but none were found on representatives of both *Oreochromis* and *Serranochromis*.

1 *Cichlidogyrus dossoui* and *C. tiberianus* typically infect representatives of *Coptodon*, but are
2 also found on other host genera. *Cichlidogyrus halli* and *C. zambezensis* are typical of,
3 respectively, representatives of *Oreochromis* and *Serranochromis*. Although Lake Kariba is
4 highly similar to Bangwuelu-Mweru in parasite and host fauna, the two systems are
5 hydrographically and ecologically very different. Lake Kariba is a man-made lake created as a
6 result of the construction of a hydroelectric dam. This dam transformed the previously
7 riverine environment into a lake system, thereby impacting the ethology/ecology of host
8 species. Such transition creates an environment where new host-parasite encounters can occur
9 (Combes, 1990). In other words, the transition from a river to a lake system may favour a
10 broader host range for parasites and a higher tendency for host switching through more or new
11 encounters between host species. In Lake Ossa, Cameroon, a broader host range for several
12 parasites was also observed following host switching. *Scutogyrus vanhovei* Pariselle, Bitja
13 Nyom & Bilong Bilong, 2013 occurs on *Coptodon mariae* (Boulenger, 1899) instead of on a
14 mouth-brooding host (Pariselle & Euzet, 2009). Also, *Quadriacanthus euzeti* Nack, Pariselle
15 & Bilong Bilong, 2015 occurs in Lake Ossa on *Papyrocranus afer* (Günther, 1868)
16 (Osteoglossiformes) instead of on a host belonging to the Siluriformes (Pariselle *et al.*, 2013;
17 Nack *et al.*, 2015). Other noteworthy examples of host switching within *Cichlidogyrus* are *C.*
18 *amieti*, *C. nandidae* and *C. inconsultans* from small forest streams in South Cameroon, as
19 these species infect non-cichlids (Pariselle & Euzet, 2009; Messu Mandeng *et al.*, 2015). The
20 extended host range in South Cameroon is probably the result of a host switch away from
21 cichlids (Messu Mandeng *et al.*, 2015). The pattern observed in the Mweru-Luapula subregion
22 is that the fauna is determined by the host taxon up to the level of host genus in most cases,
23 because the parasite species found behave as intermediate specialists to intermediate
24 generalists (coinciding with the ancestral state for host specificity for
25 *Cichlidogyrus/Scutogyrus*, see Mendlová & Šimková, 2014). However, our results may
26 demonstrate that the host range of a parasite species may differ between regions. For example
27 *C. zambezensis* is a generalist in Lake Kariba because it occurs on the distantly related hosts
28 *O. mortimeri* and *S. macrocephalus* (Douëllou, 1993), but in Bangweulu-Mweru it is limited
29 to *Serranochromis* spp., thus being an intermediate specialist there. *Cichlidogyrus*
30 *zambezensis* was not found on the local *O. mweruensis* in Mweru-Luapula of which a
31 sufficient number of hosts were investigated. We propose that there is a geographic pattern to
32 host-specificity (Krasnov *et al.*, 2004 and Korralo-Vinarskaya *et al.*, 2009) and host-parasite
33 dynamics (Valois & Poulin, 2015) in species of *Cichlidogyrus/Scutogyrus*, which implies that
34 distribution and host-specificity are not only taxon bound but also determined by ecology and

1 geography. However, a formal statistical analysis is in order to further investigate this. A
2 thorough parasitological screening of Luapula-Mweru and other regions with a highly similar
3 cichlid species composition (Upper Zambezi, Upper Congo, Lualaba River and the
4 Bangwuelu-Chambeshi subregion) (Van Steenberge *et al.*, 2014) has not yet been done; and
5 would be of great interest in further unravelling a geographic pattern to host-specificity and
6 host-parasite dynamics. Also, this would help to answer the question posed in Vanhove *et al.*
7 (2013) as to whether the biogeographical pattern of species of *Cichlidogyrus/Scutogyrus*
8 mirrors the host biogeography, or whether parasite assemblages are basin specific.

10 **Acknowledgements**

11 This research was supported by the Belgian Federal Science Policy Office (BRAIN-be
12 Pioneer Project BR/132/PI/TILAPIA), the University Development Cooperation of the
13 Flemish Interuniversity Council (VLIR-UOS, South Initiative *Renforcement des capacités*
14 *locales pour une meilleure évaluation biologique des impacts miniers au Bangweulu-Mweru*
15 *sur les poissons et leurs milieux aquatiques*, ZRDC2014MP084) and the Mbisa Congo
16 project, a framework agreement project of the RMCA with the Belgian Development
17 Cooperation. M.P.M.V. was supported by a travel grant from the Research Foundation –
18 Flanders (FWO-Vlaanderen) and Czech Science Foundation project no. P505/12/G112
19 (ECIP). Moise Katumbi Chapwe is cordially thanked for his kind hospitality and support.
20 Also E. Abwe, B. Katemo Manda and C. Mukwene Mulele are cordially thanked for their

24 (2014). Ectoparasites of Nile tilapia (*Oreochromis niloticus*) in cage farming in a
25 hydroelectric reservoir in Brazil. *Revista Brasileira de Parasitologica Veterinária* **23:2** doi:
26 10.1590/S1984-29612014041.
- 27
28 **Zengeya, T.A., Booth, A.J., Bastos, A.D.S. & Chimimba, C.T.** (2011). Trophic
29 interrelationships between the exotic Nile tilapia, *Oreochromis niloticus* and indigenous
30 tilapiine cichlids in a subtropical African river system (Limpopo River, South Africa).
31 *Environmental Biology of Fishes* **92**, 479–489.

32 **Table 1** Overview of the occurrence of monogenean gill parasites of the studied cichlid species in
 33 Bangweulu-Mweru. An ‘x’ represents the occurrence of the species on the corresponding host, while a
 34 ‘H’ represents a new host record for this parasite. A ‘*’ represents the first time this parasite was
 35 found in the ecoregion. The host-specificity is divided in strict specialists (SS), intermediate specialists
 36 (IS), intermediate generalists (IG) and generalists (G) (Mendlová & Šimková, 2014). Host range data
 37 based on Pariselle & Euzet (2009); Vanhove *et al.* (2013) and supplemented with our own findings.

2 59 **Fig. 1** Map of Bangweulu-Mweru and neighbouring ecoregions in underlined, cursive font.
3 60 Rivers and water bodies in blue, cursive font. Sampling localities in red. The inset shows the
4 61 location of Bangweulu-Mweru on the African continent. Sampling localities: 1 Luapula River
5 62 off Kashobwe, 2 Futuka Farm, 3 Bumaki Farm, 4 Lubumbashi Zoo and 5 Kipopo. Scale in
6 63 km.
7 64

8 65 **Fig. 2** Haptoral and genital hardparts of *C. consobrini* sp.n. Upper MCO drawn from the
9 66 holotype from *S. mellandi*. Lower MCO displays the MCO from a different angle and from *O.*
10 67 sp. ‘Mambilima’ I–VII uncinuli, Ap accessory piece, DB dorsal transverse bar, DH dorsal
11 68 anchor, He heel, MA male apparatus, Pe penis, VB ventral transverse bar, VH ventral anchor.
12 69 Scale 20 µm.
13 70

14 71 **Fig. 3** Stacked phasecontrast micrographs of *C. consobrini* sp.n. from *Sargochromis mellandi*.
15 72 a) haptor b) MCO and of *C. halli* morphotype 2 c) haptor and d) MCO. Scale a,b 20 µm; c,d
16 73 50 µm.
17 74

18 75 **Fig. 4** Haptoral and genital hardparts of *C. halli* morphotype 2. I–VII uncinuli, Ap accessory
19 76 piece, DB dorsal transverse bar, DH dorsal anchor, He heel, MA male apparatus, Pe penis,
20 77 VB ventral transverse bar, VH ventral anchor. Scale 20 µm.
21 78

22 79 **Fig. 5** Haptoral and genital hardparts of *C. papernastrema* from *T. sparmanii*. Left dorsal
23 80 anchor drawn from different individual. I–VII uncinuli, Ap accessory piece, DB dorsal
24 81 transverse bar, DH dorsal anchor, He heel, MA male apparatus, Pe penis, VB ventral
25 82 transverse bar, VH ventral anchor. Scale bar 20 µm.
26 83

27 84 **Fig. 6** Stacked phasecontrast micrographs of *C. papernastrema* from *T. sparmanii*: holotype
28 85 a) haptor, b) MCO and from voucher c) MCO; of *C. quaestio* from *C. rendalli* d) haptor and
29 86 e) MCO and from *Cichlidogyrus* sp. from *T. mylodon* f) haptor. Scale a,d and f 50 µm; b,c
30 87 and e 20 µm.
31 88

32 89 **Fig. 7** Haptoral and genital hardparts of *C. quaestio* from *C. rendalli*. I–VII uncinuli, Ap
33 90 accessory piece, DB dorsal transverse bar, DH dorsal anchor, He heel, MA male apparatus, Pe
34 91 penis, VB ventral transverse bar, VH ventral anchor. Scale bar 20 µm.
35 92

36 93 **Fig. 8** Haptoral and genital hardparts of *C. zambezensis* from *S. thumbergi*. I–VII uncinuli, Ap
37 94 accessory piece, DB dorsal transverse bar, DH dorsal Anchor, He heel, MA male apparatus,
38 95 Pe penis, VB ventral transverse bar, VH ventral anchor. Filaments associated with anchors
39 96 and uncinuli in grey. Scale bar 20 µm.
40 97

41 98 **Fig. 9** Stacked phasecontrast micrographs of *C. zambezensis* from *S. thumbergi* a) haptor, b)
42 99 MCO. Scale 20 µm.
