Use of Endophytic and Rhizosphere Bacteria To Improve Phytoremediation of Arsenic-Contaminated Industrial Soils by Autochthonous Betula celtiberica Supplementary material

Mesa, Victoria; NAVAZAS, Alejandro; Gonzalez-Gil, Ricardo; Gonzalez, Aida; WEYENS, Nele; Lauga, Beatrice; Gallego, Jose Luis R.; Sanchez, Jesus & Isabel Pelaez, Ana (2017) Use of Endophytic and Rhizosphere Bacteria To Improve Phytoremediation of Arsenic-Contaminated Industrial Soils by Autochthonous Betula celtiberica. In: APPLIED AND ENVIRONMENTAL MICROBIOLOGY, 83(8), p. e03411-e03416.

DOI: 10.1128/AEM.03411-16 Handle: http://hdl.handle.net/1942/24119 1 Supplemental material for Mesa *et al.*, "Use of endophytic and rhizosphere bacteria to improve

phytoremediation of arsenic-contaminated industrial soils by autochthonous Betula celtiberica"

2 3

4 A. Supplemental Methods

5 **The contaminated site.** The present study was conducted at the abandoned fertilizer industry, Nitrastur, 6 located in Langreo, Asturias (NW Spain) (See Figure S1). Nitrastur was one of the main fertilizer plants in 7 Spain for more than fifty years until its closure in 1997. The contaminated site has a total surface area of 8 20 ha (1). More than half of the surface corresponds to landfills between 4 and 5 m deep comprised of 9 pyrite ashes and other iron and steel-type debris. A scheme of the soil location and working area is shown 10 in Figure S1.

11

12 DNA extraction and 454 pyrosequencing. The primers 799F and 1391R were selected to minimize 13 chloroplast contamination by providing considerable mismatches with chloroplast sequences (<0.1% of 14 total sequences retrieved) (2). Since the concentration of bacterial DNA in comparison with the plant DNA 15 was low, we chose a nested PCR strategy to amplify the samples. A first round of PCR amplification was 16 conducted using primers without the Roche 454 pyrosequencing adaptors and sample-specific barcode. 17 Products obtained from triplicate PCR reactions were pooled and purified using the QIAquick PCR 18 purification kit (Qiagen Benelux B.V., the Netherlands), the quality of the amplicon pools was evaluated 19 using an Agilent 2100 Bioanalyzer system (Agilent Technologies, Belgium), and DNA concentration of 20 amplicon libraries was determined using Quant-iT PicoGreen dsDNA Assay Kit (Invitrogen, CA, USA) and a 21 Fluostar Omega plate reader (BMG Labtech, Germany) and pooled in equimolar concentrations.

22

23 Identification and phylogenetic affiliation of cultivable B. celtiberica-associated bacteria. Genomic DNA 24 of the purified strains was extracted from bacterial colonies collected directly from Petri dishes using the 25 GeneMATRIX bacterial and yeast Kit (EURx, Poland). For bacterial strain identification, the 16S rRNA gene 26 was amplified by PCR using the universal bacterial primers 27f (5'-GAGTTTGATCACTGGCTCAG-3') and 27 1492r (5'-TACGGCTACCTTGTTACGACTT-3') and then partially sequenced from the 27f primer (3). Briefly, 28 PCR amplicons were generated using AmpliTag Gold 360 (Applied Biosystems[®], Life TechnologiesTM, USA) 29 and 100 ng μ l⁻¹ of template DNA. The amplifications were performed in a MJ Mini Thermal Cycler (Bio-30 Rad, USA) with an annealing temperature of 56°C for 30 cycles. The PCR products obtained from separate 31 reactions were pooled and purified using Ilustra GFX[™] purification kit (GE Healthcare, UK) and DNA 32 concentrations of the pools were determined via Qubit dsDNA assay kit (Invitrogen). Amplicons were 33 sequenced according to the BigDye Terminator v3.1 sequencing kit protocol (Applied Biosystems®) 34 adjusted to a final volume of 10 µL. PCR products were purified through Sephadex G-50 (Amersham 35 Biosciences, UK), and subjected to capillary electrophoresis in an ABI PRISM® 3130xl Genetic Analyzer 36 (Applied Biosystems®). The sequences were compared to the GenBank database using the BLAST 37 algorithm (National Center for Biotechnology Information, USA). The phylogeny of the rhizosperic and 38 endophytic cultivable bacteria associated with B. celtiberica were reconstructed using partial 16S rRNA 39 gene sequences. Sequences were aligned using ClustalW (4) and phylogenetic analyses were conducted 40 with MEGA v6 (5). The evolutionary distances were inferred using the Kimura-2 parameter model. Initial 41 tree(s) for the heuristic search were obtained automatically by applying Neighbor-Join and BioNJ 42 algorithms to a matrix of pairwise distances estimated using the Maximum Composite Likelihood (MCL), 43 and then selecting the topology with superior log likelihood value.

44 The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The 45 analysis involved 119 nucleotide sequences. All positions with less than 95% site coverage were eliminated. 46 There were a total of 323 positions in the final dataset. The branches were tested with bootstrap analyses 47 (1,000 replications). iTOL (6) was used to visualize and color tree branches based on taxonomy. The 48 sequences reported in this study have been deposited in GenBank (http:// 49 www.ncbi.nlm.nih.gov/Genbank/index.html) with accession numbers: KX881424 to KX881508.

50

51 Characterization of Cultivable Isolates. The Minimum Inhibitory Concentration (MIC) for Arsenic is 52 defined as the lowest concentration of As^{III} and As^V that inhibited bacterial growth on agar medium. The 53 bacterial isolates were streaked on LB agar plates supplemented with increasing concentrations of 54 arsenite (2-20 mM) (NaAsO₂, Sigma-Aldrich, USA) or arsenate (1-100 mM) (Na2HAsO4 [•] 7H2O, Sigma-55 Aldrich, USA) (7, 8). For each strain, the lowest concentration that inhibited visible growth at 30°C within 56 7 days was determined. Indole-3-Acetic Acid (IAA) is known to facilitate plant growth (9). Strains were 57 assayed for their ability to produce IAA according to the methods described by (10) and (11). Isolates were 58 grown in 20 mL Luria Bertani broth supplemented with 500 µg mL⁻¹ tryptophan as IAA precursor and 59 incubated at 28°C for 3 days with 150 rpm shaking. After centrifugation, 1 mL of each culture supernatant 60 was mixed with 2 mL Salkowski's reagent (2 ml 0.5M FeCl₃ + 49 ml water + 49 mL 70% perchloric acid), 61 and incubated for 30 min in the dark. Absorbance at 530 nm was measured and IAA was quantified using 62 a standard curve with known concentrations of pure IAA (Sigma-Aldrich, USA). Another important plant 63 growth-promoting property (PGP) trait evaluated is 1-Amino-Cyclopropane-1-Carboxylic Acid (ACC) 64 Deaminase Activity, which antagonizes ethylene synthesis cleaving ACC, the immediate precursor of 65 ethylene (12). ACCD activity was determined by the presence of α -ketobutyrate, which is generated by 66 ACC hydrolysis (13). Siderophores are low-molecular-weight Fe(III)-specific ligands which can solubilize 67 and sequester iron from the soil and provide it to plant cells (14). Siderophore production was evaluated 68 qualitatively (15). Bacterial isolates were streaked on blue agar plates containing Chromeazurol S (CAS; 69 Sigma-Aldrich, USA), incubated at 27°C for 5 days, and the presence of orange halos around the colonies 70 was then verified.

71

72 Determination of total non-protein thiol (NPT) compounds, arsenic content and speciation in plant 73 tissues. The extraction procedure for NPTs was conducted in a cold chamber (4°C); plant material (500 74 mg) was homogenized in 1% polyvinylpolypyrrolidone and 0.1 N HCl at a ratio 1:1.5 (w/v). The mixture 75 was shaken for 30 sec and sonicated for 5 min. After centrifugation at $15,000 \times g$ for 15 min at 4°C, the 76 supernatant was collected with a syringe and filtered through a Millex-HV (0.45 μ m diameter, Merck 77 Millipore) filter. Finally, it was distributed in 150 μ l aliquots in vials and immediately injected into a high-78 performance liquid chromatograph (HPLC). HPLC was performed using a Waters 600 chromatograph 79 (Milford, MA) and the derivatized thiols were detected with a Waters 996 Photodiode-Array Detector 80 (Milford, MA). The sample (100 µl) was injected into a Kromasil[®] C18 Column (Scharlau) and eluted with 81 solvent A (acetonitrile: H₂O, 2:98 (v/v) to which 0.05% trifluoroacetic acid (TFA) was added). Post-column 82 derivatization was conducted with Ellman's reagent at 0.5 mL min⁻¹ flow (16) and absorbance was 83 measured at 412 nm. Standard samples of GSH and a mixture of PCs (PC2, PC3, and PC4) were run to 84 identify peaks. PC concentrations were analyzed using the integration areas at 412 nm absorbance 85 converted into nmoles of GSH equivalents g⁻¹ fresh weight.

Chemical As analysis were determined in leaves and roots, 0.2 g of powdered plant samples were dissolved with 8 mL of 50% nitric acid solution (Sigma, Aldrich, USA) using a microwave at 800W for 15 min (Multiwave3000, Anton Paar). The solutions were diluted to 50 mL with ultrapure water and filtered through a 0.45-μm polytetrafluorethylene (PTFE) filter prior to analysis. Plant samples were analyzed by ICP-MS as described above for soil samples (see plant material, rhizosphere soil sampling, and chemical analysis in Materials and Methods). For each sample, three independent replicates were measured. Concentration of As was expressed in mg kg⁻¹ dry weight (dw) of plant material. As speciation was

93 determined in leaves, roots, and in the culture medium in which the plants grew.

For As species determination in leaves and roots, 100 mg of finely-ground sample were extracted in 2.5 mL of nitric acid solution (0.3 M) at 95 °C for 90 min. The culture medium was directly extracted with the

- 96 nitric acid solution. The extracts were centrifuged at 6,000 X g for 15 min and the supernatants were
- 97 filtered through a 0.45-µm PTFE filter. The solutions were neutralized by adding NaOH. The As species
- 98 (As^{III}, As^V, methylarsinic acid, and dimethylarsinic acid) were separated with a mobile phase of 2 M PBS
- 99 (Phosphate Buffered Saline)/0.2 M EDTA (pH = 6.0) in a separation column with a 1260 Infinity HPLC
- 100 coupled to a 7700 ICPMS (both from Agilent Technologies). Identification of As species was confirmed by
- 101 spiking real extracts with a mixture of standard solutions.
- 102

103 Field experiments. Soil samples from each subplot were collected (at a depth of 25–30 cm), dried, mixed, 104 and sieved (through a 2-mm sieve) and the metal(loid) content was determined by ICP-MS as described 105 above. B. celtiberica plants were propagated in vitro for 30 days and acclimated to greenhouse conditions 106 uncovering the vessels and placing them in a mist tunnel at 15-25°C and 90% humidity. After 3 days, the 107 plants were transferred to 10-cm diameter pots filled with peat: vermiculite (1:1) and progressively 108 decreasing the humidity to 60% for 15 days. After this period, plants were kept in the greenhouse for 10 109 days before being placed outside and translocated to the experimental plot. For field inoculation, bacteria 110 were grown separately in 500 mL Erlenmeyer flasks containing 100 mL of GAE medium with continuous 111 shaking at 30°C to reach 10⁸-10⁹ cells per mL (24-48 h). Cells were collected by centrifugation at 8,000 X g 112 during 10 min, washed and re-suspended with sterile distilled water. Bacterial suspensions (100 mL) were 113 directly placed in contact with the roots for 20 min before covering with soil.

114

115 As phytoextraction efficiency index determination. Arsenic phytoextraction was assessed through the 116 estimation of indices: i) Bioconcentration factor (BCF) calculated as the ratio of arsenic concentrations in 117 plant tissues and soil (BCF = C_{root}/C_{soil}), values of BCF > 1 indicating the accumulation of a particular trace 118 metal in roots; ii) mobility ratio (MR) calculated as the ratio of heavy metal in above-ground plant parts 119 (shoots, branches, or leaves) to those in soil (MR = $C_{above ground plant part}/C_{soil}$), values of MR > 1 indicating that 120 the plant is enriched with metals; iii) translocation factor (TF) calculated as the ratio of arsenic 121 concentrations in above-ground plant parts to those in roots (TF = Cabove ground plant part=Croot), values of TF > 122 1 indicating that the plant translocates metals effectively from root to shoot (17, 18).

130 B. Supplemental Figures

- 131 Supplementary Figure 1. (A and B) Location of the fertilizer industry "Nitrastur" site in Spain (Asturias
- 132 region, Langreo municipality). (C) Aerial view of the site where the red thread delimits the Nitrastur
- 133 industry area and the black lines show the sampled grid delineating 100 X 100 m plots. (**D**) Zoom of the
- 134 NC5 and NC6 sampling plots, the phytoremediation area is outlined in violet.

153 Supplementary Figure 2. (A) Correlation between the mean (per plot and treatment) of the residuals 154 from the model $y = a + As \ soil + pH + \varepsilon$ (see Material and Methods in the main text) of the shoot 155 biomass or plant height index and the mean of the residuals from the same model of leaf or root As 156 concentrations of Betula celtiberica plants. Dot labels indicate whether plants were inoculated (E, with 157 Rhizobium herbae strain 32E; R, with Ensifer adhaerens strain 91R; BC, with the bacterial consortium 158 including Variovorax paradoxus strain 28EY and Phyllobacterium myrsinacearum strain 28EW and BCF, 159 with the same consortium but with fertilizer) or not (C and FC for control and fertilized control, 160 respectively). Dashed lines mark the zero value. The shaded areas represent the 95% confidence intervals 161 of each linear relationship (black solid lines). The slope (b) and R^2 (proportion of variance explained) of 162 each relationship are also shown. (B) Means and their corresponding 95% confidence intervals (dots and 163 error bars) of the same residuals analyzed in (A), although only per treatment. Horizontal dashed lines 164 mark the zero value.

Supplementary Table 5. pH and metal(loid) concentrations (mg kg⁻¹) in soil samples taken in the
experimental phytoextraction area. Values are the average of three samples with a standard error < 5%.
Plots are named according to subsequent treatment: plants inoculated with *Rhizobium herbae* strain 32E
(E), *Ensifer adhaerens* strain 91R (R), or bacterial consortium composed of *Variovorax paradoxus* strain
28EY and *Phyllobacterium myrsinacearum* strain 28EW (BC and BC+F correspond to bacterial consortium
without or with fertilizer, respectively) and non-inoculated plants (control, C and fertilized control, FC).

Treatment	Plot	рН	Cr	Ni	Cu	Zn	As	Cd	Hg	Pb
