Abstract

The factor structure of the Motorcycle Rider Behaviour Questionnaire (MRBQ) was investigated in Vietnam, a developing country with an extensive motorcycling culture. In addition, we examined which of the MRBQ factors, riding information and demographic variables predict motorists' crash risks and traffic violations. Exploratory factor analysis (EFA) of the MRBQ revealed a clear four-factor structure of 36 items (N=2.254 riders). This study highlights some critical differences between motorists from Vietnam and other countries. Vietnamese riders without a driver's licence had lower on-road crash/near-crash rates, and the use of safety equipment paradoxically increased the incidence of crash risks. Furthermore, crash/near-crash liability and offences of Vietnamese motorcyclists rose with riding years (in terms of years already riding a motorcycle). The 36-item version of the MRBQ provided in this paper may be applied to other motorcycling countries. Besides, based on the robust relationships between the MRBQ factors and accident risks, new effective on-road safety strategies can focus on minimizing the common aberrant riding behaviours such as traffic errors, control errors, speed and alcohol-related violations in Vietnam.

Keywords: motorcycling, MRBQ, on-road crash risk, traffic offences, Vietnam

13 **Highlights**

- 14 • A representative sample of 2254 observations was collected in Danang, Vietnam.
- 15 • Factor analysis of the MRBQ showed a clear 4-factor structure of 36 items.
- 16 • Motorists often ride even when the required traffic safety conditions are not satisfied.
- 17 • Females report lower rates of collision risks and offences than males.
- 18 • Crash/near-crash liability and offences of riders increased with riding years.

19 1. Introduction

20 Motorcycles have become an essential way of ensuring active participation in social and eco-
21 nomic activities for the vast majority of citizens living in countries where motorcycling is widespread.
22 Nonetheless, the large number of motorcycles, in addition to the inherent dangerous characteristics
23 of the motorcycle-traffic environment, pose substantial threats to motorists (Jadaan et al., 2018;
24 Vlahogianni et al., 2012; WHO, 2017). World Health Organization figures show that motorcyclists
25 account for 43% of all deaths in South-East Asia (WHO, 2018). Particularly, Vietnam’s National
26 Traffic Safety Committee reported more than 8.500 deaths each year from on-road crashes, whereas
27 about 90% of victims were motorcyclists and their passengers. Vietnam’s economic losses are more
28 than \$2 billion per year due to traffic accidents, of which the motorcycling share of about 75%
29 (United Nations, 2018). Thus, improving safety for motorcyclists is a matter of urgency.

30 Aberrant riding behaviours are important contributors to traffic accidents (Evans, 1993; Lin
31 & Kraus, 2009; Ngo et al., 2012; Kitamura et al., 2018). Many studies have highlighted the
32 main causes of motorcycle crashes are traffic errors and violations (Vlahogianni et al., 2012). The
33 National Traffic Safety Committee of Vietnam also reported that aberrant riding behaviours such
34 as speeding and unsafe overtaking/lane-shifting accounted for more than 60% of all road fatalities in
35 this country (Tuan, 2015). An understanding of riding behaviours among motorcyclists has become
36 a prerequisite when trying to identify the causes of motorcycling accidents (Hung & Huyen, 2011;
37 ITF, 2015).

38 Road safety literature has emphasized the essential role of the self-reported survey in the
39 investigation of riding behaviour around the world (Elliott et al., 2007; Sullman & Taylor, 2010).
40 Following the success of the Driver Behaviour Questionnaire (De Winter & Dodou, 2010; Reason
41 et al., 1990), one of the most widely used instruments for investigating four-wheeled vehicles driving
42 behaviours, the Motorcycle Rider Behaviour Questionnaire (MRBQ) was developed to measure
43 motorcycle-related riding behaviours (Elliott et al., 2007). There are five factors in the original
44 MRBQ, i.e. traffic errors (unintentional mistakes made by the rider), control errors (motorcycle
45 handling lapses), speed violations, performance of stunts (intended excitement seeking actions) and
46 use of safety equipment. After the creation of MRBQ, a variety of alternative factor structures
47 were proposed, and supplementary questions were added to the initial questionnaire (Table 1).
48 For instance, items that were perceived as “Performance of stunts” among British motorists, were
49 classified under “Control/Safety” (acts in the context of losing control and safety) in the study

50 concerning Nigerian riders (Sunday, 2010). The observed distinction between “Traffic errors” and
 51 “Control errors” was not manifest among novice Australian motorists, which resulted in a single
 52 “Errors” factor (Sakashita et al., 2014).

Country (author)	Sample size	% male	Factors: items from Table A.8 + authors' additional items
United Kingdom (Elliott et al., 2007)	8666	92.0	Traffic errors: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13 Speed violations: 14, 15, 16, 17, 18, 19, 20, 21, 22 Stunts* ¹ : 23, 24, 25, 26 Control errors: 35, 36, 37, 38 Safety equipment** ² : 27, 28, 29, 30, 31, 32, 33, 34
Iran (Motevalian et al., 2011)	518	100.0	Traffic errors: 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12, and 1 additional item Speed violations: 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, and 1 additional item Safety violations: 34, and 6 additional items Traffic violations: 5 additional items Stunts: 23, 24, 25, 26, 35, 36, and 1 additional item Control errors: 37, 38, 39, 40, and 2 additional items
Turkey (Özkan et al., 2012)	451	100.0	Traffic errors: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 Speed violations: 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 22, 40 Stunts: 21, 23, 24, 25, 26, 42 Safety equipment: 27, 28, 29, 30, 31, 32, 33, 43 Control errors: 35, 36, 37, 38, 39
Australia (Sakashita et al., 2014)	2375	79.2	Traffic errors: 1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 22, 35, 36, 37, 38 Speed violations: 14, 15, 16, 17, 18, 19, 21 Stunts: 23, 24, 25, 26 Safety equipment: 27, 28, 29, 30, 33
Malaysia (Ng et al., 2015)	204	84.8	Traffic errors: 1, 2, 5, 6, 7, 8, 9, 10, 11, 12, 13 Speed violations: 14, 15, 16, 17, 18, 19, 20 Stunts: 21, 22, 23, 24, 25, 26, 41 Safety devices: 27, 28, 29, 30, 32 Control errors: 35, 36, 37, 38
Australia (Stephens et al., 2017)	470	89.0	Traffic errors: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 Speed violations: 14, 15, 16, 17, 18 Stunts: 21, 23, 24 Control errors: 12, 13, 35, 36, 37, 38 Protective gear: 27, 28, 29, 30, 32
Nigeria (Oluwadiya, 2018)	500	100.0	Control/Safety: 23, 24, 26, 29, 31, 35, 38, 40, 41, and 2 additional items Stunts: 12, 13, 18, 22, 37, and 2 additional items Errors: 1, 3, 36, and 1 additional item Speeding/Impatience: 7, 10, 11, 15, 21, 25, and 1 additional item
Slovenia (Topolšek & Dragan, 2018)	205	86.3	Traffic errors: 1, 2, 3, 5, 6, 7, 11, 16 Speed violations: 18, 19, 20, 21 Stunts: 23, 25, 26, 27, 28 Safety equipment: 29, 30, 31, 32, 40, and 3 additional factors: Helmet: 3 additional items, Clothing: 3 additional items, Alcohol: 3 additional items

Table 1: The MRBQ factor structures across countries. *Performance of stunts - **Use of safety equipment

53 The differences in MRBQ outcomes across studies highlight important variations in on-road

54 traffic safety between countries, and further research should adopt the MRBQ to investigate the
55 riding behaviours in countries with high motorcycle dependence (Hsu et al., 2003).

56 Various methods for determining riding behaviours and the relationship between riding be-
57 haviours and accident involvement have been suggested in previous research (Vlahogianni et al.,
58 2012). When direct observation and official traffic records are not systematically collected due
59 to limited resources, the ability of MRBQ, which can provide a report of how a person rides in
60 different traffic circumstances, would improve its utility in motorcycle safety research and practice.
61 One of the most valuable applications of the MRBQ is to identify behaviours which increase the
62 likelihood of motorcycle accidents. For instance, traffic/control-related errors and speed violations
63 are some of the most significant behavioural factors that affect motorcyclists' accident risks (Elliott
64 et al., 2007; Sakashita et al., 2014; Vlahogianni et al., 2012). Meanwhile, performance of stunts was
65 the unique MRBQ factor correlated with crash involvement among Australian motorists (Stephens
66 et al., 2017). Similarly, this factor was the primary determinant of active accidents (i.e. hitting
67 another road user or an obstacle) and traffic offences (related to parking, overtaking, speeding
68 or other traffic violations) for Turkish riders (Özkan et al., 2012). The factor of using the safety
69 equipment emerged from all of the studies mentioned above but was not likely to be a determinant
70 of crash or near-crash incidents. Ensuring the validity and reliability of the MRBQ is of great
71 importance for the evaluation of the interventions aimed at motorcyclists.

72 Most of the validation and application of MRBQ studies were conducted in high-income coun-
73 tries such as the United Kingdom Elliott et al. (2007), Australia (Sakashita et al., 2014; Stephens
74 et al., 2017), Slovenia (Topolšek & Dragan, 2018), or in nations where most of the motorcyclists
75 ride for pleasure or sensation-seeking like Iran (Motevalian et al., 2011), and Turkey (Özkan et al.,
76 2012). There is also a need to investigate riding behaviours in low- and middle-income countries
77 with a large dependency on motorcycles.

78 The Vietnam Association of Motorbike Manufacturers announced that Vietnam has more than
79 50 million motorcycles, and up to 79% of the population uses a motorcycle for regular riding
80 (VAMM, 2018). This makes Vietnam one of the top countries in terms of motorcycle dependence.
81 However, a limited number of studies concerning riding behaviours in Vietnam have been conducted
82 and provided decisive insights for policymakers and traffic managers. Previous research efforts only
83 focused on one specific riding behaviour, such as wearing a helmet, using a mobile phone while
84 riding, drinking-driving or speeding (Bao et al., 2017a; Gruyter et al., 2017; Mohamad et al., 2018;

85 Ngo et al., 2012; Trinh & Le, 2016; Truong et al., 2016). Consequently, this research was motivated
 86 by the urgent need for a more comprehensive understanding of riding behaviours by using MRBQ
 87 and addressing motorcycling safety issues within the context of Vietnam. The purposes of this
 88 study are (i) to analyze the factor structure of Vietnamese MRBQ, and (ii) to investigate the
 89 relationships between the MRBQ factors, background variables, riding information and accident
 90 involvements and traffic violations in Vietnam.

91 2. Material and method

92 2.1. Data collection

93 Data collection was conducted in Vietnam, and consists of three sections: (i) demographic and
 94 riding experience background, (ii) information about self-reported traffic accidents and received
 95 violation tickets, and (iii) the MRBQ. Trained students from the University of Danang delivered
 96 the paper-based questionnaire to the participants at parking lots and residential areas. Only
 97 people who have ridden a motorcycle were invited to participate in this survey, and they were
 98 assured of confidentiality and anonymity. Initially, the total number of motorcyclists interviewed
 99 for this survey was 2823. The final dataset includes 2254 observations after deletion of incomplete
 100 observations. Tables 2 and 3 present the descriptive statistics of the sample.

Variable	Description	N	Mean	Std. Dev.
Age	Age of the motorcyclist	2254	24.3	5.9
Riding years	Total years of riding a motorcycle	2254	6.1	5.2
License years	Total years of holding a driver's license	2254	4.9	4.7
Mileage	Average annual mileage (km)	2233	4863.8	4769.5
Near crashes	Number of near crashes (last 12 months)	2241	1.5	3.5
Crashes	Number of crashes (last 12 months)	2253	0.9	1.8
Offences	Number of penalized traffic violations (last 12 months)	2253	0.24	0.93

Table 2: Basic descriptive statistics: continuous variables

Variable	N	Category	Frequency	Proportion (in %)
Gender	2250	Female	1650	73.3
		Male	600	26.7
Highest education level attained	2254	Elementary school	7	0.3
		Secondary school	23	1.0
		High school	82	3.6
		Bachelor / Engineer	2044	90.7
		Master / PhD	68	3.0
		Others	30	1.3
Holding a driver's license	2254	No	156	6.9
		Yes	2098	93.1
Riding frequency	2254	Everyday	1953	86.6
		Several times per week	253	11.2
		Once a week	14	0.6
		Less than once a week	34	1.5
Main riding purposes	2246	Carry for free	18	0.8

		Yes	882	39.1
Have traffic offence in the past 12 months	2254	No	1918	85.1
		Yes	336	14.9

Table 3: Basic descriptive statistics: categorical variables

101 *2.2. Measures*

102 *2.2.1. Demographic questions*

103 The questionnaire included items asking participants' socio-demographic background, e.g. age,
104 gender, education level, and their riding information, e.g. licence tenure, riding purpose, riding
105 frequency, average riding distance per year and self-reported traffic accidents and traffic violations.
106 To assess riding incidents, the following formulation was adopted: "During the last 12 months,

107 how many near-crashes / crashes / penalized traffic violations have you had?". In this study, we
108 defined "near-crash" as "dangerous traffic situations where motorcyclists are fortunate enough to
109 escape from the collision", and "crash" as "a traffic accident involvement leading to injuries, and/or
110 material damage". Those definitions are consistent with the study in Australia (Sakashita et al.,
111 2014), which defined "motorcycle crashes" as "collisions with someone or something, or coming off
112 the bike but excluding dropping or knocking it over while parked" and "near-crash" as "almost
113 had a crash but did not".

114 2.2.2. The Motorcycle Rider Behaviour Questionnaire (MRBQ)

115 The original MRBQ has 43 items, and for each item, the respondents are asked to rate the
116 frequency of their riding behaviour during last year by choosing one option from the 6-point scale:
117 1=never, 2=hardly ever, 3=occasionally, 4=quite often, 5=frequently, and 6=nearly all the time.
118 The use of this scale provided good reliability with Cronbach alpha coefficients for the five factors
119 ranging from 0.70 to 0.84 (Elliott et al., 2007). Two researchers used the back-translation technique
120 to translate MRBQ from English to Vietnamese. With 20 Vietnamese motorcyclists and two traffic
121 police officers, we held focus group discussions to find out what they understood from each question
122 and noted unclear items. We defined the final list of items by taking into account the feedback
123 from the discussions in the focus group.

124 2.2.3. Methodology

125 Regarding the information gaps within the MRBQ, missing values were replaced by the mean
126 of the non-missing observations for that variable. In this respect, mean imputation was performed
127 on 190 data points, corresponding to a negligible 0.2% of the overall dataset.

128 Before exploring the factor structure of the MRBQ, the models presented in Table 1 were
129 assessed using Confirmation Factor Analysis (CFA) on our collected dataset. The CFA was es-
130 timated with an asymptotically distribution-free estimation configuration. In case those existing
131 models would poorly fit the data, Principal Axis Factoring (PAF) and Direct oblimin rotation
132 methods were applied to investigate the factor structure of the Vietnamese MRBQ. Furthermore,
133 the internal consistency of the MRBQ scale scores was estimated by systematically computing the
134 Cronbach's alpha reliability coefficients.

135 Finally, the associations between demographic variables, riding information, MRBQ factors
136 and self-reported yearly crash outcomes, including near-crashes, crashes and traffic offences, were

137 analyzed using negative binomial regression (see Figure 1).

138 **3. Results**

139 *3.1. Sample description*

140 A basic statistical description of the collected sample is presented in Tables 2 and 3. The
141 mean age was 24.3 years, ranging from 20 to 71 years old, and about 73% of participants were
142 female. Young riders and university graduates accounted for large proportions of our sample.
143 This was the group of Vietnamese people who always wanted to contribute ideas for improving the
144 current traffic conditions (Nguyen-Phuoc et al., 2019; Nguyen et al., 2013). Thus, they participated
145 actively and responsibly in our survey. However, it is important to enlarge the range of demographic
146 backgrounds when sampling of Vietnamese riders in future work.

147 The majority of participants held a driver's licence. 86.6% of respondents said that they rode
148 every day, and almost 96% used the motorcycle to go to work/study sites. The average riding
149 period was 6.1 years, and the mean duration of possessing the licence was 4.9 years. The mean
150 annual riding distance was 4863.8 kilometres. Typically, the motorcycle is used for short trips in
151 motorcycling countries; thus, these findings are within expectations.

152 In terms of crash involvement, 39.1% of the participants reported to be involved in at least one
153 crash over the last 12 months, and 55.8% of the sample reported to have encountered at least one
154 near-crash scenario. In addition, 14.9% of the sample was penalized for traffic violations in the
155 last year.

156 *3.2. MRBQ item scores*

157 The results obtained from this research are in line with most of the previous studies (Elliott
158 et al., 2007; Motevalian et al., 2011; Özkan et al., 2012; Sakashita et al., 2014; Stephens et al.,
159 2017; Sunday, 2010; Topolšek & Dragan, 2018), which find that the MRBQ responses are typically
160 between "never" and "hardly ever". Vietnamese motorists indicated that the most common be-
161 haviours were linked to safe riding. For instance, on the scale ranging from 1 (never) to 6 (almost
162 all the time), the two highest-scoring items were item 35 "Brake or throttle back (slow down)
163 when going around a bend" ($M=4.560\pm 1.309$) and item 36 "Change gears when going around a
164 corner or bend" ($M=4.500\pm 1.360$). The motorcycle's relative lack of protection may cause riders
165 to appreciate their additional vulnerability (Huth et al., 2014). As a result, they generally take a

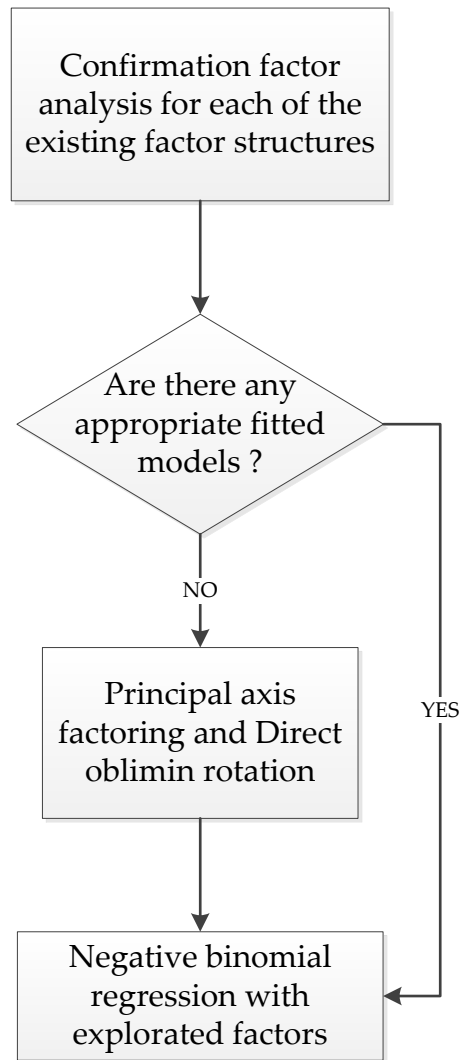

Figure 1: Factor analysis pathway

166 defensive approach on the road, with a tendency to be less aggressive while riding (Rowden et al.,
167 2016).

168 On the other hand, items relating to the use of safety equipment had fairly low ratings, for exam-
169 ple, item 43 "Wear bright/fluorescent clothing" ($M=1.430\pm 0.833$), item 33 "Wear bright fluorescent
170 strips/patches on your clothing" ($M=1.490\pm 0.947$). Noticeably, item 31 "Wear no protective cloth-
171 ing", which also related to the use of protective equipment, had a high score ($M=3.940\pm 1.800$).
172 Generally, those behaviours are extremely rare among Vietnamese motorcyclists due to the lack of
173 road traffic laws on protective gear while riding, except for the mandatory helmet legislation from
174 August 2000 (Hill et al., 2009; Hung et al., 2008; Bao et al., 2017a).

175 3.3. Factor analysis of MRBQ

176 A CFA has been applied to validate the internal structure of the MRBQ. Model fitting is
177 systematically evaluated with the Chi-squared/degree of freedom (χ^2/df) ratio, the Goodness-of-
178 Fit Index (GFI), the Adjusted Goodness-of-Fit Index (AGFI), the Comparative Fit Index (CFI),
179 the Root Mean Square Residual (RMR), and the Root Mean Square Error of Approximation
180 (RMSEA, RMSEA CL90) (Byrne, 2016). In general, appropriate fitted models should have 2/1
181 or 5/1 as χ^2/df ratio, GFI >0.9 (Jöreskog & Sörbom, 1986), AGFI >0.9 (Tanaka & Huba, 1985),
182 CFI >0.9 (preferably >0.95) (Bentler, 1990), and RMSEA and RMR <0.08 or 0.01 (preferably
183 <0.06) indexes (Browne et al., 1993).

184 Since no model had given a reasonable fit of the Vietnamese sample (Table 4), this data was
185 re-examined within an EFA framework (Hu & Bentler, 1998; Thompson, 2007). The 43 items were
186 subjected to PAF in order to determine the factor structure. Initially, eight factors had eigenvalues
187 higher than 1.0. Based on the Scree plot and the parallel analysis, a 4-factor solution was retained.
188 The Direct oblimin rotation method was applied because there had been some relatively high
189 inter-correlations. The factor analysis was then rerun designating four factors.

Model	χ^2/df	GFI	AGFI	CFI	RMR	RMSEA	LO 90	HI 90
UK	5.08	0.84	0.82	0.51	0.2	0.04	0.041	0.044
Turkey	5.65	0.82	0.8	0.44	0.2	0.05	0.044	0.047
Australia (2014)	5.91	0.79	0.76	0.44	0.21	0.05	0.045	0.048
Malaysia	5.13	0.83	0.80	0.53	0.19	0.04	0.041	0.044
Australia (2017)	5.53	0.83	0.80	0.56	0.18	0.05	0.043	0.047
Nigeria	7.22	0.87	0.87	0.42	0.21	0.05	0.050	0.055
Slovenia	5.50	0.90	0.87	0.48	0.18	0.05	0.042	0.047

Table 4: Goodness-of-fit statistics for competing models of the MRBQ

190 The possibility of using the factor analysis results without concerns is checked by applying the
191 Bartlett's Test of Sphericity (BTS) and the Kaiser-Meyer-Olkin (KMO) test (Lohnes, 1971). The
192 BTS value was noticeably significant: $\chi^2(630) = 37916.7$ ($p < 0.001$) and the KMO value was 0.92
193 > 0.5 . Consequently, the BTS and KMO values indicated that the EFA could be reliably used for
194 further analysis, in accordance with the recommendations (Field, 2013).

195 When interpreting the rotated factor patterns, six items from original MRBQ (i.e. item 12, 13,
196 31, 34, 39, 40) had low weights for all factors, and item 19 "Open up the throttle and just go for it
197 on a country road" had high cross-loading. Therefore, these items were removed from the analysis.
198 Based on the remaining 36 MRBQ items, the four factors explained 43.5% of the total variance.
199 Questionnaire items and the corresponding factor loadings were shown in Table 5, while a loading
200 value of 0.3 was used as a cut-off point.

201 The first factor explains 25% of the total variance. It is composed of nine items related to
202 control errors and therefore labelled "Control errors" (CE). Two items (35, 36) were considered
203 as the actions to avoid on-road risks, so they had negative factor loadings. Factor 2 accounts for
204 10% of the overall variance and included 13 items. All items were related to unintended mistakes
205 made by the riders, so factor 2 was named "Traffic errors" (TE). Eight items fall under factor 3,
206 which explains about 5% of the total variance. This factor was referred to as "Safety equipment"
207 (SE), which involved the use of protective gears to improve the safety of the riders. Factor 4
208 included six items relating to speed infringements (with the exception of item 41). Item 41 "Ride
209 when you suspect you might be over the legal limit for alcohol" is the only item of the original
210 MRBQ relating to drunk driving. Subsequently, this factor was labelled "Speed and Alcohol-related

Item	Mean	Std. Dev.	Control errors	Traffic errors	Safety equipments	Speed and Alcohol-related Violations
35 Brake or throttle back (slow down) when going around a bend	4.56	1.31	-0.47			
36 Change gears when going round a corner or bend	4.50	1.36	-0.46			
20 Ride between two lanes of fast moving traffic	1.52	0.83	0.47			
22 Ride so fast into a corner that you scare yourself	1.57	0.85	0.47			
26 Unintentionally do a wheel spin	1.32	0.74	0.56			
21 Got involved in racing other riders or drivers	1.39	0.78	0.58			
24 Pull away too quickly and your front wheel lifted off the road	1.29	0.71	0.65			
25 Intentionally do a wheel spin	1.26	0.72	0.65			
23 Attempt or done a wheelie	1.28	0.70	0.67			
37 Find that you have difficulty controlling the bike when riding at speed (eg steering wobble)	3.09	1.31		0.34		
10 When riding at the same speed as other traffic, you find it difficult to stop in time when a traffic light has turned against you	2.37	1.16		0.34		
38 Skid on a wet road or manhole cover, road making	2.63	1.11		0.38		
3 Not notice a pedestrian waiting at a crossing where the lights have just turned red	2.08	1.05		0.38		
1 Fail to notice that pedestrians are crossing when turning into a side street from a main road	2.64	0.99		0.43		
5 Miss Give Way signs and narrowly avoid colliding with traffic having right of way	2.11	1.05		0.51		
9 Attempt to overtake someone that you had not noticed to be signaling a right turn (in England, left turn in other countries)	2.24	0.97		0.51		
11 Ride so close to the vehicle in front that it would be difficult to stop in an emergency	2.65	1.02		0.57		
2 Not notice someone stepping out from behind a parked vehicle until it is nearly too late	2.75	1.02		0.57		
8 Distracted or pre-occupied, you suddenly realize that the vehicle in front has slowed, and you have to brake hard to avoid a collision	2.86	0.98		0.62		
7 Queuing to turn left (in England, turn right in other countries) on a main road, you pay such close attention to the mainstream of traffic that you nearly hit the car in front	2.58	1.00		0.62		
6 Fail to notice or anticipate another vehicle pulling out in front of you and had difficulty stopping	3.22	1.02		0.63		
4 Pull onto a main road in front of a vehicle you have not noticed or whose speed you misjudged	2.84	1.02		0.63		
33 Wear bright fluorescent strips/patches on your clothing	1.49	0.95			0.57	
43 Wear bright/fluorescent clothing	1.43	0.83			0.62

violations" (SAV), and explained a further 3.5% of the total variance.

All factors had good reliability with the Cronbach's alpha, ranging from 0.82 to 0.89, and shared weak to moderate correlations (Table 6), indicating that each factor appears to measure a conceptually distinct construct. In this context, the four-factor structure proved to be reasonably interpretable.

3.4. Predicting traffic crash accident and offences

The sample data of traffic accidents and penalized violations did not follow the normal distribution, and initially violated the assumption of equi-dispersion. In order to set up a predictive

Table 6: The correlations among demographic variables, the number of traffic accidents, offences, and MRBQ factors. **: $p < 0.01$; *: $p < 0.05$; Gender: 1=Male, 2=Female; Have a driver’s license: 1=Yes, 0=No

219 model for motorcycle accidents and offences in Vietnam, a negative binomial regression analysis
220 was performed (Denham, 2016). The following predictors were selected in the analysis: age, gen-
221 der, highest education level achieved, possession of a driver’s licence, the total number of years
222 already riding a motorcycle (riding years), years of holding a driver’s licence, annual riding dis-
223 tance (mileage), ownership of motorcycle and MRBQ factors. The results of the negative binomial
224 regression analysis were presented in Table 7.

225 As shown in Table 7, the motorcyclist’s gender, age, riding years and traffic errors were the
226 major predictors of accident involvements and traffic offences. According to the incidence rate
227 ratios (IRR), males were expected to have higher rates than females for the annual total number of
228 crashes, near-crashes and offences, i.e. 20%, 16% and 83.3% more, respectively. The motorcyclist’s
229 age was negatively related to the overall number of accident chances and penalized violations,
230 whereas riding years and traffic errors had positive relationships with them. The factor of control
231 errors was associated significantly and positively with the total number of motorcyclists’ crashes
232 and offences. Unexpectedly, 1.092 times more crashes were reported for each increment in the use of
233 safety equipment. The total number of near-crashes and penalized violations grow by about 14%,
234 with each rise of one unit of speed and alcohol-related violation factor. Furthermore, the analysis
235 revealed that unlicensed riders tend to be involved in crash and near-crash circumstances at lower
236 rates than motorists with a valid licence. Participants without private motorcycle appeared to

237 have 23.6% more near-crash experiences than owners of motorcycles.

238 4. Discussion

239 The literature review revealed a research gap on riding behaviour and its outcomes in Viet-
240 nam, a nation with 86% of the households owning at least one motorcycle (United Nations, 2018;
241 Miaschi, 2019). Therefore, this study focused on validating the MRBQ and investigating the re-
242 lationship between Vietnamese motorcyclists' demographic variables, riding information, MRBQ
243 factors, accident risks and traffic offences. There was a difference in the composition of our data
244 sample with respect to the higher proportion of women (73.3% of participants), whereas men pre-
245 dominated in previous studies (Table 1). Since we are correcting for gender, at least the main
246 effects are taken into account, the co-occurrence between gender and other explanatory factors
247 may be neglected, given that the variance inflation factors were all relatively close to 1. Given
248 this study's higher percentage of females, the overall incidence of involvement in accidents is lower
249 than expected, as males are more closely linked to motorcycle crashes (Al-Balbissi, 2003; Stanoje-
250 vić et al., 2018; Vlahogianni et al., 2012). In Vietnam, males participated more frequently in traffic
251 accidents than females, and especially, men were expected to have 83.3% more than women for the
252 annual number of penalized traffic violations (Table 7). In terms of gender differences, men also
253 reported substantially more dangerous driving behaviours than women in prior research (Bachoo
254 et al., 2013). Therefore, new on-road safety initiatives should be specially targeted at males in
255 order to raise their safety awareness (Hoekstra & Wegman, 2011).

256 The MRBQ factor structures identified in earlier research did not apply to the sample of
257 Vietnamese motorists. Instead, the new Vietnamese MRBQ was revealed based on the results of
258 factor analysis, including four factors: control errors, traffic errors, safety equipment and speed &
259 alcohol-related violations. This 4-factor structure was consistent with the Australian and Nigerian
260 studies (Sakashita et al., 2014; Sunday, 2010). Nevertheless, the composition of the factors differed
261 considerably between these studies.

262 With regard to the proposed MRBQ, the control errors factor includes nine items that have
263 been perceived as stunts (items 21, 23, 24, 25, 26), errors (items 35, 36) or speed violations (items
264 20, 22) in previous studies (Table 1). Vietnamese riders recognize these items in the context of
265 losing control or proactively keeping themselves safe instead of intentionally stunting or violating
266 on the road (Hsu et al., 2003; WHO, 2017; ?). This factor shows the critical distinction between

267 countries in riding patterns and on-road safety perceptions of motorcyclists.

268 Considering that traffic errors have been reported as the most frequent cause of collision involve-
269 ment in previous studies ([Gruyter et al., 2017](#); [Hung & Huyen, 2011](#)), our work further underlines
270 the relevance of these traffic errors to the risk of traffic accidents and violations. Recall from
271 (Table 1), that in contrast to factor structures in previous studies, in our study the traffic errors
272 factor does not include items relating to speed infringements (item 13, 16, 22) or control errors
273 (item 12, 35, 36). All thirteen items of the traffic errors factor were related to riders' unintended
274 mistakes while riding. This result complements the idea that traffic errors are often associated
275 with motorcyclists' risk perceptions or observational abilities ([Sunday, 2010](#)). It is worth noting
276 that Vietnamese motorists were more likely to commit to traffic errors than other forms of MRBQ
277 behaviours (Table 5). Moreover, with each increment of one unit in traffic errors, their crash, near-
278 crash and offence rates are increasing by more than 20% (Table 7). The undesired prominence
279 of traffic errors can be explained by the fact that riding a motorcycle is an extremely demanding
280 task with specific skills, much more complicated than driving a car ([Elliott et al., 2007](#)). To avoid
281 traffic errors in Vietnam, the design of on-road warning signs should be more intuitive, and the
282 training program for motorcyclists should include the guidance to identify traffic situations that
283 often cause these errors ([Giang, 2019](#); [Ou & Liu, 2012](#)).

284 The use of personal protective clothing is extremely uncommon in countries with the highest
285 motorcycle usage, including Thailand, Vietnam, Indonesia, Malaysia ([Kumphong et al., 2018](#);
286 [Miaschi, 2019](#); [Lili et al., 2016](#); [Solah et al., 2019](#)). Although the number of motorcycle-related
287 accidents is abnormally high, Vietnamese motorists stated that they are not yet in the habit of
288 using safety equipment when riding ([Bao et al., 2017b](#); [Trinh & Le, 2016](#)). This can be explained
289 by the fact that, aside from the mandatory use of helmets, there are no restrictions on the usage
290 of motorcycle protective clothing in Vietnam. Especially, given the sense of increased protection
291 by using additional protective gear, Vietnamese riders tend to commit more traffic errors, making
292 them more likely to get involved in collisions ([United Nations, 2018](#)). This study shows that the
293 incidence of crash risks among Vietnamese motorists rose by 9.2%, with each increment in the use
294 of safety equipment (Table 7). These findings are different from the studies carried out in developed
295 countries, where most motorcyclists consider the use of protective items as a prerequisite for safe
296 riding ([Stephens et al., 2017](#)). Motorcycling in Vietnam is the result of irregular traffic patterns
297 ([Doan & Hobday, 2019](#); [Ngoc & Thanh, 2020](#); [Nguyen-Phuoc et al., 2020](#)). In this regard, we

298 suggest further research to evaluate the effectiveness of various safety equipment for the riders in
299 motorcycling countries (?).

300 Item 41 “Ride when you suspect you might be over the legal limit for alcohol” was dropped from
301 most of the previous MRBQ factor structures (Table 1) due to low loading scores. In contrast, this
302 item had a moderate factor loading in the Vietnamese MRBQ, so it was retained within the speed
303 and alcohol-related violation (SAV) subscale. The retention of item 41 in the MRBQ is beneficial
304 for the analysis of the association between drunk riding and the traffic risk within the Vietnamese
305 context.

306 Besides, all five remaining items of the SAV factor are related to speed infringements. Our
307 finding highlights a positive correlation between riding under the influence of alcohol and high-
308 risk behaviours, such as speeding and violating traffic rules, which were also emphasized in other
309 research (Cherpitel et al., 2003; Pereira et al., 2011; Tran et al., 2012; Zhao et al., 2014). While there
310 have been "Drunk No Driving" and "Speed Limit Violations Prevention" campaigns in Vietnam,
311 these infringements continue to be critical factors of traffic problems (Ngoc et al., 2012; Phuong
312 et al., 2016; Vu et al., 2019). In this nation, the number of near-crashes and penalized violations
313 increased by approximately 14%, with each rise of the SAV factor (Table 7). It is appropriate to
314 install more speed traps and tighten control over drunk riding to improve road safety and reduce
315 speed and alcohol-related accidents in Vietnam (Barrett et al., 2017; Mohamad et al., 2018; Stewart
316 et al., 2012; Wickramarachchi, 2013).

317 In addition to the points mentioned above, the results of the negative binomial regression
318 analysis provide some additional insights into the current motorcycling environment in Vietnam.

319 Young riders in Vietnam have higher rates of crash/near-crash and traffic offence (Table 7).
320 A combination of lack of experience and a propensity to engage in risky behaviours may explain
321 the higher risk for them, as described in prior studies (?). Similarly, the Vietnamese who borrows
322 a motorcycle has a significantly higher near-crash rate on the road compared to those who own
323 a motorcycle. This finding is in line with the results previously published (Haworth et al., 1994;
324 Reeder et al., 1995; ITF, 2015).

325 Surprisingly, Vietnamese motorists without a riding licence have lower crash/near-crash rates
326 than licensed riders. There is a different tendency in other studies, where unlicensed riders are
327 more likely to violate traffic regulations and to be involved in accidents (Curry et al., 2015; Kraus
328 et al., 1991; ITF, 2015). We assume that unlicensed Vietnamese motorists may be more cautious

329 while riding because they are concerned about being penalized by the traffic police and recognize
330 their additional risks due to a lack of road safety knowledge. This assumption may explain the
331 reduction in their rate of collision involvement. However, future research is suggested to assess the
332 efficiency and effectiveness of Vietnam's motorcycle training and licensing system (Daniello et al.,
333 2009).

334 The probability of motorists' crash/near-crash and offences slightly increased with the cumu-
335 lative riding years in Vietnam (Table 7). In this country, where most people spend considerable
336 time motorcycling inside a traffic system with inherent chaotic characteristics, the number of rid-
337 ing years may positively correlate with the likelihood of traffic accident involvement (Fagnant &
338 Kockelman, 2015). This result poses requirements for further investigations into the relationships
339 between Vietnamese personality traits, attitudes toward on-road safety, traffic environment and
340 riding outcomes. Firstly, given the lack of questions in the current MRBQ to evaluate common rid-
341 ing behaviours in motorcycle-traffic environments, this questionnaire could be extended by adding
342 items related to "use of cell phone while riding," "aggressive riding," "use of impaired motorcycle"
343 or "carrier violations" for potential studies. Secondly, when using the self-reporting approach for
344 data collection, there are some concerns regarding biases. Nevertheless, participants were carefully
345 explained about the purposes of the study and were assured of confidentiality and anonymity; thus,
346 the influence of social desirability bias is likely to be negligible.

347 5. Conclusions

348 The proposed version of the MRBQ was smartly adapted to investigate on-road crash risks and
349 penalized traffic violations among Vietnamese motorcyclists. The factor analysis of the MRBQ
350 using our collected sample data revealed a notable four-factor structure grouping a total of 36
351 items. This study also highlighted the robust relationships between motorists' age, gender, the
352 MRBQ factors and accident risks and traffic offences. The findings with respect to motorcycling
353 in Vietnam may be value for decision-makers and practitioners to improve the motorcycle training
354 and licensing system, on-road safety campaigns and development of more effective traffic inter-
355 ventions. Particularly, avoiding common aberrant riding behaviours such as traffic errors, control
356 errors and speeding and alcohol-related violations would significantly reduce the traffic risks for
357 Vietnamese motorists. Regarding the possible recommendations, more efforts need to be directed
358 towards quantifying and verifying the association between motorists' personality traits, risky riding

359 behaviours and traffic risks in countries with significant usage of motorcycles.

361 This study has been supported by the Wallonie-Bruxelles International (Project 2.17). The
362 authors would like to thank Mr Le Quoc Dan, Deputy Director of Department of Public Security
363 in Danang, Vietnam for his valuable comments regard the content and the validity of the ques-
364 tionnaire, and AMIGOS team (University of Economics – The University of Danang) for the data
365 collection process.

366 **Appendix A. Appendix**

Item	Content
1	Fail to notice that pedestrians are crossing when turning into a side street from a main road
2	Not notice someone stepping out from behind a parked vehicle until it is nearly too late
3	Not notice a pedestrian waiting at a crossing where the lights have just turned red
4	Pull onto a main road in front of a vehicle you have not noticed or whose speed you misjudged
5	Miss "Give Way" signs and narrowly avoid colliding with traffic having right of way
6	Fail to notice or anticipate another vehicle pulling out in front of you and had difficulty stopping
7	Queuing to turn left (in England; turn right in other countries) on a main road, you pay such close attention to the mainstream of traffic that you nearly hit the car in front
8	Distracted or pre-occupied, you suddenly realize that the vehicle in front has slowed, and you have to brake hard to avoid a collision
9	Attempt to overtake someone that you had not noticed to be signaling a right turn (in England; left turn in other countries)
10	When riding at the same speed as other traffic, you find it difficult to stop in time when a traffic light has turned against you
11	Ride so close to the vehicle in front that it would be difficult to stop in an emergency
12	Run wide when going around a corner
13	Ride so fast into a corner that you feel like you might lose control

- 14 Exceed the speed limit on a country/rural road
- 15 Disregard the speed limit late at night or in the early hours of the morning
- 16 Disregard the speed limit on a motorway
- 17 Disregard the speed limit on a residential road
- 18 Race away from traffic lights with the intention of beating the driver next to you
- 19 Open up the throttle and just go for it on a country road
- 20 Ride between two lanes of fast moving traffic
- 21 Got involved in racing other riders or drivers
- 22 Ride so fast into a corner that you scare yourself
- 23 Attempt or done a wheelie
- 24 Pull away too quickly and your front wheel lifted off the road
- 25 Intentionally do a wheel spin
- 26 Unintentionally do a wheel spin
- 27 Wear motorcycle riding boots
- 28 Wear protective trousers – leather or non-leather
- 29 Wear a protective jacket – leather or non-leather
- 30 Wear body armour/impact protection for the elbows and shoulders
- 31 Wear no protecting clothing
- 32 Wear motorcycle gloves
- 33 Wear bright fluorescent strips/patches on your clothing
- 34 Use daytime headlights on your bike
- 35 Brake or throttle back (slow down) when going around a bend
- 36 Change gears when going round a corner or bend
- 37 Find that you have difficulty controlling the bike when riding at speed (e.g. steering wobble)
- 38 Skid on a wet road or manhole cover, road making
- 39 Have trouble with your visor or goggles fogging up
- 40 Another driver deliberately annoys you or puts you at risk
- 41 Ride when you suspect you might be over the legal limit for alcohol
- 42 Wear a full leather-suit
- 43 Wear bright/fluorescent clothing
